**Preserving rubber.** B. D. PORRITT, T. R. DAWSON and RESEARCH ASSOCN OF BRITISH RUBBER & TYRE MANUFACTURERS. Brit. 299,169, Sept. 29, 1927. Rubber goods are coated with a mixt. contg. substances resistant to light and air, e. g., a mixt. formed of soft "mineral rubber" 60, aldol  $\alpha$ -naphthylamine 10, "Oil Red S" 2 and toluene 100 parts.

**Recovery of rubber.** MAURICE dit RENÉ GATTEFOSSE and SOC. FRANÇAISE DE PRODUITS AROMATIQUES, ANCIENS ÉTABLISSEMENTS GATTEFOSSE. Fr. 649,726, July 19, 1927. Vulcanized rubber is recovered by dissolving or treating it with an ester such as ethyl decylate, the alc. of which is not a solvent for rubber, and eliminating the ester by sapon. Cf. C. A. 23, 732.

**Artificial rubber.** KATHERINE B. G. EDMONDSTONE and DONALD CHAUVEL. Australia 10,433, Nov. 16, 1927. Artificial rubber consists of cactus or other wax-like plants, with or without the leaves of vinca or periwinkle plant, white vinegar or AcOH and S.

**Rubber substitute.** HOWARD W. MATHESON (to The Can. Electro Products Co., Ltd.). Can. 288,640, Apr. 9, 1929. The compn. specified includes clay, rubber, S, ZnO, coloring matter, and a product made by treating vinyl ester with an aldehyde

"Synthetic rubber." J. BAER. Brit. 298,889, Oct. 15, 1927. An aldehyde such as  $\text{CH}_3\text{O}$  is treated with alkali metal or alk. earth metal polysulfides in soln. with or without conjoint use of a halogen deriv. of a satd. hydrocarbon such as ethylene or methylene dichloride or dibromide. A rubber-like product is formed.

**Making tires from synthetic rubber produced by polymerization of butadiene.** I. G. FARBERIND. A.-G. Brit. 299,037, Oct. 20, 1927.

**Puncture-sealing composition.** W. C. P. TANNER. Brit. 299,542, Aug. 9, 1927. Gum tragacanth which has been heated to at least  $85^\circ$ , water,  $\text{CH}_3\text{O}$  and a fibrous filler such as asbestos are used together. Carrageen and agar agar may be substituted for part of the tragacanth.

**Aldehyde-amine condensation products for use as rubber vulcanization accelerators.** S. M. CADWELL (to Naugatuck Chemical Co.). Brit. 298,537, Nov. 1, 1926. Derivs. such as those contg. Cl, Br or I are formed from the condensation product of heptaldehyde and aniline or other similar condensation products of an aliphatic aldehyde having 2-7 C atoms and a primary amine. Various examples are given of the prepn. of different accelerators from these condensation products by use of halogenating and other reagents such as Cl, Br, I, acids, alc. and Na, HCl, Zn and Sn, etc. Cf. C. A. 22, 3068.

**Apparatus for vulcanizing tire flaps or other endless bands of rubber.** D. S. HARRINGTON (to Goodyear Tire and Rubber Co.). Brit. 299,005, Oct. 19, 1927.

**Rubber vulcanization.** J. TEPPERMA (to Goodyear Tire and Rubber Co.). Brit. 298,942, Oct. 17, 1927. Accelerators are used comprising mercaptotrazoles or their derivs. such as reaction products with amines such as diphenylguanidine, diethylamine, butylamine and benzylamine (which may be prepd. by mixing solns. of the azole and the amine in hot alc.). Mercaptonaphthotrazole is prepd. by treating  $\beta$ -naphthol with  $\text{HNO}_3$  to form a nitroso deriv., which is then treated with Na hydrosulfide and  $\text{CS}_2$ .

**Vulcanizing rubber.** J. TEPPERMA (to Goodyear Tire & Rubber Co.). Brit. 298,622, Oct. 13, 1927. An accelerator is used which comprises the reaction product of a hydroxy aromatic aldehyde and an amine, e. g.,  $\beta$ -hydroxynaphthaldehyde and aniline may be heated under a reflux condenser to produce a yellow cryst. compd. which on heating gives off an oil and leaves a resinous residue which acts as an accelerator; or the aldehyde and amine may be heated for 1-2 hrs. in a closed vessel at  $300^\circ$  to form the accelerator.

# CHEMICAL ABSTRACTS

Vol. 23.

JULY 20, 1929

No. 14

## 1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

**An apparatus for exhibiting determinations of melting and boiling points.** WALTER SCHMIDT. *Chem. Fabrik* 1929, 279.—A modified Thiele m.-p. app. for use with a projector. J. H. MOORE

**A dispensing buret for strong alkali.** E. F. ALMY. *J. Chem. Education* 6, 734-5 (1929).—An inverted 1.25 X 8" lipless test tube has a 3-hole stopper, 1 for the supply tube from the elevated stock bottle, 1 for the delivery tube and 1 for a vent tube, the inner arm of which extends to the top of the test tube and the outer arm to the level of the top of the stock bottle. The test tube is marked with labels for different vols. of soln. J. H. MOORE

**Apparatus for filling pipets and burets with corrosive substances.** ROBERT F. McCrackan. *J. Chem. Education* 6, 733(1929).—A 2-hole stopper in the stock bottle carries a rubber bulb pump, with hole in the neck to relieve pressure, and a funnel tube reaching nearly to the bottom of the bottle. A ground-glass stopper in the mouth of the tube carries a No. 00 rubber stopper through which the tip of the pipet or buret passes into the soln. when blown up the funnel tube. Cf. *C. A.* 22, 1499; 23, 1779. J. H. MOORE

**An automatic pipet.** MAURICE HYMAN. *J. Soc. Chem. Ind.* 47, 368T(1928).—The measuring pipet is cut off at the graduation mark and the neck fitted into a wide overflow stoppered tube having a mouth piece connected with rubber tubing. C. H. B.

**New desiccator and inset.** H. LIESEGANG. *Chem. Fabrik* 1929, 256-7.—The app. is rectangular, giving a better utilization of the inner space. J. H. MOORE

**A simple interferometer for measuring small layer thicknesses.** HANS FROMHERZ AND WILHELM MENSCHICK. *Z. physik. Chem., Abt. B*, 2, 399-404(1929).—The app. and method of operation are described. The layer thicknesses of 2 flat bulbs of about 10 $\mu$  and 50 $\mu$  thickness were measured to 0.2%. F. D. ROSSINI

**A safeguard for stock solutions.** E. F. ALMY. *J. Chem. Education* 6, 735(1929).—Description, with 1 cut, of a device for operating a pinchcock placed near the top of the siphon supply line from the stock bottle to the bottom of burets with a 2-way cock, to prevent loss of soln. due to a break in the line. J. H. MOORE

**A new viscometer; system Michell.** ANON. *Mat. grasses* 21, 8459-65(1929).—The viscometer consists of a steel or cast-iron head with a concave surface; it is provided with a handle in which fits a thermometer reaching to the steel head. Three small protrusions in the head prevent a ball made of steel from coming in contact with the head and at the same time regulate the thickness of the film of liquid under test. The viscosity is measured by the time necessary for the ball to detach itself from the head, when suspended downward. A great rapidity of test, precision, simplicity and direct measure of viscosity, irrespective of the density of the liquid, are claimed. P. T.

**The Plonait colorimeter.** I. MEYER. *Farben-Ztg.* 34, 1955-6(1929).—The soln. (2 g./50 cc.) of the sample contained in a cell 20 mm. thick and the soln. of the standards contained in hollow glass wedges are, by means of totally reflecting prisms, simultaneously viewed through a slit. The wedges are moved until a color match is obtained. Two standards are provided, one a soln. of a very pale rosin, two a soln. of a very dark grade. Either or both of the wedges may be used in obtaining the color match. The app. may also be used to det.  $p_H$  values by filling the wedges with basic and acidic solns. contg. an indicator. From the relative positions of the wedges when the sample contg. the same percentage of indicator is matched, the  $p_H$  value may be calcd. G. G. S.

**Differential manometer functioning by air under pressure; determination of the velocity and of the flow of fluids.** F. BORDAS AND F. TOUPLAIN. *Bull. soc. encour. ind. natl.* 1929, 257-65.—The following are discussed in considerable detail: 1. Detn. of flow by the use of manometers: (1) general considerations; (2) differential manometers of 1 or 2 liquids furnished with Pitot outlet tubes and functioning by means of

air under pressure. II. Principles and characteristics of the manometric system: (1) simple manometer; (2) differential liquid manometer; (A) remarks and observations: (a) influence of the aperture of the air exit tubes; (b) density of manometric liquids; (3) manometer of 2 liquids; (A) the law regulating its functioning; (4) static and dynamic outlet tubes. III. Installations of the app.: (1) manometer app. and its accessories; (2) one-liquid manometer; (3) two-liquid manometer; (A) manometer scales; (B) mode of operation; (C) calibration of the app.; (D) characteristics and advantages of the process. IV. Recording manometer. A. J. MONACK

The Pulfrich stage photometer as a turbidity-measuring instrument. STEFAN GÄRTNER. *Kolloid-Z.* 48, 10-5(1929).—Directions are given for the use of the Pulfrich stage photometer with slight changes in the glass receptacles for the measurement of turbidity. If the extinction coeff. of the turbid soln. is directly proportional to the concn., then the concn. may be exactly evaluated from the extinction coeff. by this method; otherwise, it cannot. L. F. MAREK

Filtering equipment and the systematic and continuous extraction of sludges, precipitates and ores. G. FOURTON. *Chimie & industrie* Special No., 175-80(Feb. 1929).—A discussion of the advantages of the horizontal, continuous, rotary vacuum filter and its application in the production of phosphoric acid from phosphate rock, in the extn. of Zn from low-grade ores, in the washing of sugar-house scums and in the extn. of drainings from centrifuges in the manuf. of sugar. A. PAPINEAU-COUTURE

Jena glass filtering crucibles. R. H. SIMON. *J. Assoc. Official Agr. Chem.* 12, 209-11(1929).—A brief discussion of the advantages of glass filtering crucibles, particularly for the detn. of  $P_2O_5$  by the volumetric method and for the detn. of K. A. PAPINEAU-COUTURE

The use of vitrified silica apparatus for the determination of metals as sulfates. A. A. GUNTZ AND J. BARBIER. *Chimie & industrie* 21, 711-2(1929).—In the detn. of Na as  $Na_2SO_4$ , ignition can be carried out in semi-transparent  $SiO_2$ -ware at  $1000^\circ$  without attacking the  $SiO_2$ , but there is appreciable loss by volatilization above  $950^\circ$ ; a min. temp. of  $700^\circ$  is required to decomp. the bisulfate or pyrosulfate formed. In the detn. of Mg, ignition should be carried out between  $600^\circ$  and  $850^\circ$ . In the detn. of Li, ignition should be carried out at  $500$ - $950^\circ$ , considerable attack of the  $SiO_2$  taking place above  $1000^\circ$ . Cd can be detd. as sulfate in  $SiO_2$ -ware at  $450$ - $800^\circ$ , above which the sulfate is decompd. into oxide, which is volatile and which attacks the  $SiO_2$ . Pb is readily detd. by ignition at  $450$ - $800^\circ$ . Mn can be detd. as sulfate by ignition at  $400$ - $750^\circ$ ; but ignition at higher temp. to obtain  $Mn_2O_3$  is not recommended. Zn can be detd. very accurately as  $ZnSO_4$  by ignition at  $400$ - $600^\circ$ ; ignition to  $ZnO$  above  $900^\circ$  results in loss by volatilization, if an open crucible is used, but is accurate with a covered crucible. Detn. of Ni and Co as sulfates is not recommended because the permissible temp. range for ignition is too small. A. PAPINEAU-COUTURE

Heat exchange in recuperators. E. TERRES AND W. BESECKE. *Gas u. Wasser-fach* 72, 417-21, 447-9, 466-9 and 476-7(1929).—Measurements and computations as to the heat exchange in recuperators are given. R. W. RYAN

Design of superheaters for high pressures and high temperatures. R. M. GATHS AND C. W. GORDON. *Power* 69, 869-72(1929).—Low-C steel can be used in superheaters up to a steam temp. of  $800^\circ F.$ , medium-C steel, up to  $850^\circ$ , *calorized steel*, up to  $1000^\circ$  and *Cr-Ni steel*, up to  $1100^\circ$ . A chart shows the relation between unit stresses and wall temps. up to  $1200^\circ$  for these materials. D. B. DILL

Small gas muffle furnace. F. W. HORST. *Chem. Fabrik* 1929, 280-1.—An improved Hempel muffle made by F. Hegershoff, Leipzig. J. H. MOORE

Boiler house Orsat set. R. N. C. PUCKERING. *Eng. Boiler House Rev.* 42, 608-12(1929). E. I. S.

Welded aluminum in the chemical and process industries. W. M. DUNLAP. *Am. Mach.* 70, 747-8(1929). E. I. S.

High-vacuum technic (KNIPP) 2. The determination of gas density with the vacuum balance. III. The electromagnetic balance for laboratory use (Strock) 2.

Air filter. LEWIS L. DOLLINGER. U. S. 1,714,854, May 28. Structural features.

Bag filter, etc., for separating dust from air. CLARENCE E. BILLINGS (to New Haven Sand Blast Co.). U. S. 1,715,273, May 28.

Centrifugal separator for dust, etc., from air or gas. CLAUDE H. CRAIG and ALBERT E. HAMILTON. Fr. 652,411, April 10, 1928.

Device for separating oil, water and air. EMIL H. STEPHAN (to William H. Gast). U. S. 1,714,825, May 28.

**Filter and gravity separator for oil and water, etc.** A. C. HANDLEY. Brit. 299,648, Jan. 20, 1928. An app. is described comprising a sepg. chamber with baffles and assoc. filtering material such as coir fiber or artificial silk.

**Filter press.** WALTER A. TYLER and RAYMOND STARK (to L. A. Dreyfus Co.). U. S. 1,714,331, May 21.

**Filter for liquids under pressure.** GRÉGORI JAVITCH and SIMON JAVITCH. Fr. 652,232, April 5, 1928. Constructional details.

**Devices for regulating temperatures according to a definite time-temperature curve.** LIVERPOOL RUBBER CO., LTD., F. AMENDE and E. D. GRIFFITHS. Brit. 300,-226, Aug. 9, 1927.

**System for calibrating thermometers and pyrometers.** N. M. HOPKINS. Brit. 300,112, Nov. 5, 1927.

**Radiation pyrometer.** CHARLES E. FOSTER. U. S. 1,714,664, May 28. Structural features.

**Vacuum tubes.** COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 652,667, April 6, 1928. Method of maintaining the electrodes in position.

**X-ray tube.** CLAYTON T. ULREY and HARRY DEF. MADDEN (to Westinghouse Lamp Co.). U. S. 1,715,150, May 28. Structural features.

**X-ray tubes.** CLAYTON T. ULREY and LOUIS F. EHREKE (to Westinghouse Lamp Co.) U. S. 1,715,151-2, May 28. Structural features.

**X-ray anode.** WILLIAM D. COOLIDGE (to General Electric Co.). U. S. 1,714,975, May 28. Structural features.

**Thermionic tubes.** ERNEST A. TUBBS. Fr. 652,568, April 6, 1928.

**Thermionic lamps.** ARCHIBALD F. POLLOCK and DAVID A. POLLOCK. Fr. 652,600, April 12, 1928.

**Thermionic valves.** J. W. MARDEN (to Westinghouse Lamp Co.). Brit. 299,715, Oct. 27, 1927. Various structural details are specified. A pellet of an alkali metal compd. and a reducing agent may be supported by a loop in a metal strip secured to the grid support. Before mounting, the anode and grid are baked in H for 5-10 mins. at 1000° to remove O, oxides and grease and the filament is straightened by flashing at 1000° in an inert gas such as "forming gas" contg. H admixed with 80% its volume of N. The completed mount is heated for 30-60 mins. at 300° in air to remove grease and dirt by volatilization or oxidation. A soln. of petroleum jelly in CHCl<sub>3</sub> or shellac, or the like, may be used to assist in sealing. In order to form a layer of electronegative gas on the filament, O or air is admitted and the filament flashed at 2000° for about 30 mins. to remove grease and hydrocarbons and to insure retention of the oxide layer formed on the filament; or, instead of directly admitting O, a pellet of CsMnO<sub>4</sub> and Si may be used and heated to a low temp. to evolve O and then further heated to 900° to drive off Cs.

**Electron discharge devices.** ALLGEMEINE ELEKTRICITÄTS-GES. (to International General Elec. Co.). Brit. 299,857, Nov. 2, 1927. Introduction of alk. earth metals into an electron discharge device is effected by heating within the envelope a mixt. of a reducing agent, which does not appreciably volatilize at the temp. of the reaction, such as Al, Be or one of the rare earth metals, and a stable alk. earth compd., which does not emit deleterious gases during the reaction, such as alk. earth oxides, aluminates or silicates. Metals such as Cu or Al, which form alloys with the alk. earth metals, may also be added. Various details of operation are given.

**Electron discharge tubes.** NAAMLOOZE VENNOOTSCHAP PHILIPS' GLOEILAMPEN-FABRIEKEN. Fr. 652,324, April 6, 1928.

**Electric discharge devices.** H. PLAUSON. Brit. 299,735, May 30, 1927. A cathode-ray app., which may be used for sterilization, for synthesis of chem. compds., for polymerization, as for conversion of isoprene into rubber, for oxidation, for chlorination and for hydrogenation of inorg. oils, is described. Part of the cathode rays may be converted into Röntgen rays by inserting a piece of quartz, mica or glass inside or outside the envelope. The window may be of flat or cellular foil of Ni, Al or Be, or alloys of Be, Mg and Al. The envelope is highly evacuated and residual gas such as N is removed by Li. Various structural details are described.

**Gas-filled discharge tube for radiation of ultra-violet light.** NAAMLOOZE VENNOOTSCHAP PHILIPS' GLOEILAMPEN-FABRIEKEN. Brit. 299,931, Aug. 12, 1927. An incandescent oxide or oxide-contg. cathode is used with one or more solid anodes (which may be C cylinders) and a gaseous filling comprising Hg vapor and a rare gas such as A; at least part of the wall is formed of quartz or of glass with an extremely low coeff. of expansion. Various structural details are described.

**Furnaces.** AMERICAN ENGINEERING Co. Fr. 652,084, April 2, 1928. Construction of walls.

**Furnaces.** FRANK B. BIGELOW. Fr. 652,508, Feb. 16, 1928. Construction of walls.

**Furnaces.** STOCKHOLMS AKTIEBOLAGET PRIVAT. Fr. 651,936, Mar. 29, 1928. Gases are withdrawn from the back of the furnace, mixed with air and introduced at the front, the rest of the furnace receiving combustion air, which has been heated only a little or not at all. If a very damp fuel is used, the gases charged with steam formed at the front of the furnace are evacuated separately.

**Gas furnace.** H. VOGT-GUT A.-G. Fr. 651,713, Mar. 24, 1928. The gas leads are arranged in a horizontal circle, the gas being directed on to a conical surface of ceramic material, so that the flames reach the center of the hearth.

**Tunnel furnaces.** RENIER JONKERGOUW. Fr. 652,616, April 12, 1928. Method of equalizing the temp. at the top and bottom of the furnace.

**Furnace for annealing ring-shaped articles such as magnetic cores for loading coils.** WILLIAM A. TIMM (to Western Elec. Co.). U. S. 1,713,790, May 21. Structural features.

**Continuous push furnace for heating billets, etc.** WILLIAM B. CHAPMAN (to Chapman-Stein Furnace Co.). U. S. 1,713,995, May 21. Structural features.

**Apparatus for indicating and regulating the air supply to furnaces utilizing different gaseous fuels.** C. LÖBBECKE. Brit. 300,204, Nov. 8, 1927. An app. is described suitable for use in regulating the use of different fuels such as coke-oven gas and blast-furnace gas.

**Automatic temperature regulators, particularly for furnaces.** FELIX JOMBART. Fr. 652,160, Nov. 7, 1927.

**Oil furnace.** M. M. SILATYEBV. Russ. 5578, June 30, 1928. Constructional features are specified.

**Oil burner.** SIDNEY E. MAJOR and EMRYS F. BAKER. Australia 12,471, Mar. 24, 1928.

**Oil burner.** V. P. KAZAKOV. Russ. 5544, June 30, 1928.

**Oil burner.** V. S. KOLOBOV. Russ. 5736, June 30, 1928.

**Oil burner.** A. I. KOTLYARENKO, F. I. KOTLYARENKO and V. I. KOTLYARENKO. Russ. 5104, April 30, 1928.

**Oil burner.** A. I. KOTLYARENKO, F. I. KOTLYARENKO and V. I. KOTLYARENKO. Russ. 5654, June 30, 1928.

**Oil burner.** M. V. PAPA-FEDOROV. Russ. 5659, June 30, 1928.

**Oil burner.** P. I. SLEPCHENKO. Russ. 5118, April 30, 1928.

**Oil burner.** V. K. VASILYEV. Russ. 5731, June 30, 1928.

**Thermostatic oil burner.** LEE S. CHADWICK (to Perfection Stove Co.). U. S. 1,715,334, May 28.

**Air-delivery apparatus for an oil burner.** GOVERNMENT SHIP BUILDING TRUST IN PETROGRAD. Russ. 5641, June 30, 1928.

**Gas burner.** ARTHUR STOCKSTROM and ISAAC V. BRUMBAUGH (to American Stove Co.). U. S. 1,714,409, May 21. Structural features.

**Gas burner.** JOHN S. ZINK. U. S. 1,715,051, May 28.

**Tunnel-type gas burner.** WILLIAM M. HEPBURN (to Surface Combustion Co.). U. S. 1,714,473, May 21. Structural features.

**Apparatus for heating fluids with steam under any desired pressure.** ARTURO CASTELLAZZI. Fr. 652,321, April 6, 1928.

**Acetylene generator.** LÉON HENRY and GUSTAVE DÉJARDIN. Fr. 652,288, April 6, 1928.

**Acetylene generator.** ERNEST MOREL and AUGUSTE ROQUET. Fr. 651,994, Mar. 30, 1928.

**Acetylene generator.** P. I. NIKULIN. Russ. 5636, June 30, 1928.

**Acetylene-gas generator under high pressure.** HANS GEBHARDT. Fr. 652,136, April 4, 1928.

**Carbide indicator for acetylene generators.** EMIL MENZ. Fr. 652,041, Mar. 31, 1928.

**Apparatus for scrubbing gas or for effecting other operations involving direct contact of gases with liquids.** FREDERICK W. SPERR, JR. (to Koppers Co.). U. S. 1,715,252-3, May 28. Structural features.

**Gas-purifying trap with a heating device for restoring absorbent qualities of material in the trap.** FRANK SCHAEFER (one-half to American Signs Corp.). U. S. 1,714,245, May 21.

- Apparatus (with rotary pumps) for mixing or blending gases.** RALPH B. STITZER and KENNETH M. WADDELL. U. S. 1,714,284, May 21.
- Apparatus for the recovery of gases or vapors by solid absorbents.** SOC. DE RECHERCHES ET D'EXPLOITATIONS PÉTROLIFÈRES. Fr. 33,710, Mar. 21, 1927. Addn. to 612,386.
- Apparatus for reëvaporating liquefied gases.** GESELLSCHAFT FÜR INDUSTRIE-GASVERWERTUNG. Fr. 651,750, Mar. 24, 1928.
- Apparatus for impregnating liquids with gases such as carbon dioxide.** HUGH S. STINSON and LESLIE STINSON (to Stinson Carbonator Co.). U. S. 1,713,787, May 21.
- Apparatus for concentrating and distilling liquids.** ANTOINE MONTUPET. Fr. 33,717, Mar. 30, 1927. Addn. to 629,395. Constructional improvements.
- Apparatus and method for mixing liquids by impinging a mist or stream of one liquid on a film or thin stream of the other.** F. E. SMITH, A. P. H. DESBOROUGH, W. T. THOMSON, H. F. REYNOLDS and E. W. BLAIR. Brit. 299,942, Aug. 26, 1927.
- Closed-circuit crystallization system.** METALLBANK UND METALLURGISCHE GESELLSCHAFT A.-G. Fr. 652,055, April 2, 1928.
- Apparatus for the production of carbon dioxide snow.** L'ACIDE CARBONIQUE PUR (SOC. ANON.). Fr. 652,094, April 3, 1928.
- Acid-proof self-lubricating cock.** MATHEW LOTZ. U. S. 1,714,606, May 28. Structural features.
- Surface condenser for steam.** JOHN F. KIRGAN (to Ingersoll-Rand Co.). U. S. 1,713,534, May 21. Structural features.
- Scrubber for preventing loss of vapors of gasoline or other volatile liquids from storage tanks.** HAROLD V. ATWELL (to Standard Oil Co. of Ind.). U. S. 1,715,112 May 28. Oil may be passed through the scrubber and into the tank.
- Rotary-drum apparatus for drying, charring, or similar treatment of loose materials.** OTTO DOBBELSTEIN. U. S. 1,714,853, May 28. Structural features.
- Digester cover.** SOC. ANON. RECORD. Brit. 299,706, Oct. 29, 1927.
- Apparatus (with screw conveyors) for continuous cooking of seeds, garbage, etc.** STANLEY HILLER. U. S. 1,715,065, May 28.
- Apparatus for distributing fire-quenching foam on floating decks of oil tanks.** CHARLES R. GALLAGHER (to Consolidated Steel Corp.). U. S. 1,714,015, May 21.
- Apparatus for applying fibrous pulp to a core such as wire.** HELGO W. JESPERSEN (to Western Electric Co.). U. S. 1,713,904, May 21. Structural features.
- Mercury air pump.** A. I. ZVEREV. Russ. 5718, June 30, 1928. Constructional features are described.
- Thermostatic valve for controlling gas supply to burners.** F. W. ROBERTSHAW and G. A. ROBERTSHAW. Brit. 300,145, June 30, 1927.
- Thermostatic control for electric circuits.** ALBERT E. WHITTIER. U. S. 1,713,578, May 21.
- Device for thermostatic and time-interval regulation of electric furnaces or other apparatus.** L. D. WEILL. Brit. 299,714, Oct. 28, 1927. Structural and electrical features are described.

**Origin of the term saponin.** FRITZ FERCHL. *Arch. Pharm.* 267, 290-309(1929).—A historical study appears to indicate Gmelin and Grothus as the first to employ the term saponin (in all probability developed from their earlier expressions: Saponarien-gummi, Kalksaponyl, Saponyl). W. O. E.

**Application of the logistic function to experimental data.** LOWELL J. REED AND JOSEPH BERKSON. *J. Phys. Chem.* 33, 760-79(1929).—A mathematical paper investigating the basic properties and some methods of analysis of the equation  $y-d = K/(1 + Ce^{rt})$ , which in logarithmic form is  $\ln\{[K-(y-d)]/(y-d)\} = \ln C + rt$  and in differential form is  $dy/dt = (r/K)[y-d][K-(y-d)]$ .  $y$  is the dependent variable,  $t$  the independent variable and the difference,  $y-d$  (in which  $d$  may equal 0) varies logarithmically with  $t$ . Mathematically the method of least squares is most proper to det. the parameters but practically this is a difficult or a useless refinement. The methods used are essentially graphic approximations which R. and B. illustrate in the evaluation of equations for positive and negative autocatalysis, bimolecular reactions with and without equal initial concns. of reactions, and oxidation and reduction potentials. A. P. SACHS

**The work of H. G. Grimm on the chemistry of atoms.** GULBRAND LUNDE. *Tids Kemi Bergvesen* 8, 27-30, 46-48, 59-62(1928). A. DROGSETH

**Fundamental atomic weights. VII. The atomic weight of potassium.** (HÖNIGSCHMID AND J. GOUBREAU. *Z. anorg. allgem. Chem.* 177, 102-8(1929).—By analysis of KBr, the value for the at. wt. of K found previously by analysis of KCl was confirmed. K oxalate was recrystd. five times, the mother liquors and small head fractions being discarded. The bromide was prepd. from purified Br, and then recrystd. The salt was dried in pure  $N_2$  at gradually increasing temp., and finally fused. Comparison with Ag was made as AgBr. The value is 39.104. L. L. QUILL

**Revision of the atomic weight of cerium.** Analysis of cerium trichloride. O. HÖNIGSCHMID AND H. HOLCH. *Z. anorg. allgem. Chem.* 177, 91-101(1929).— $CeCl_3$  was analyzed, the Ce being obtained free from La and Nd as the double Mg nitrate. The recrystd.  $CeCl_3$  was dehydrated, first in a current of  $N_2$  and HCl, then in pure HCl and finally fused. Comparison with Ag was made in the usual way, weights being corrected to vacuum. The value found is 140.125; Brauner found 140.25. L. L. Q.

**Determination of particle sizes.** DONOVAN WERNER AND STIG GIERTZ-HEDSTRÖM. *Tek. Tid. Uppf. C (Kemi)* 58, 17-23(1928); cf. C. A. 22, 4752.—A description of the app. and method for the detn. of the distribution of particle sizes in cement, emery, soils and similar materials by sedimentation analysis, previously described by D. Werner, C. A. 20, 469. Illustrated. C. A. ROBAK

**Experiments on para- and orthohydrogen.** K. F. BONHOEFFER AND P. HARTECK. *Sitzb. preuss. Akad. Wiss.* 1929, 103-8.—Quantum theory has led to the claim that mol. H is a mixt. of para- and orthohydrogen. The heat cond. of liquid H was studied at low pressure and liquid-air temp. No change was noted after 3 weeks. Gaseous H, however, contained in a brass cylinder under a pressure of 350 atm. at room temp., and then transferred to a liquid-air bath, showed a change in the ratio para- to orthohydrogen from 25/75 to 45/55. Liquid H at the same pressure showed a change in the ratio from 25/75 to 29/71 after 5 hrs., and 40/60 after 30 hrs. The heat of transition of ortho- into parahydrogen is 329 cal. at zero abs. Pure parahydrogen was obtained by adsorption on charcoal from gaseous H at the temp. of liquid H. Its heat conductance is  $1/4$  higher than that of the 1:3 mixt. At room temp. and 1 atm. parahydrogen is stable for several days. At 100 atm. conversion into orthohydrogen occurs. The temp. coeff. is small. Platinized asbestos brings about conversion in a short time. An elec. discharge has the same effect. FRANK URBAN

**Action of helium on platinum.** HORACIO DAMIANOVICH. *Compt. rend.* 188, 790-2 (1929); cf. C. A. 23, 1537.—The probable existence of He compds. in processes involving cleanup of He or He products at low temp. after activation by elec. discharge has an important bearing on valence theories. D. has made quant. expts. illustrating the absorption or chem. combination of He with Pt. One set-up consisted of a discharge tube 20 cm. long with 2 very pure Pt electrodes. Receiver tubes were inserted near the electrodes to catch the Pt-He compd. of brownish tinge. The other tube was built of quartz and had demountable electrodes. With Tube I pressure decreases of 0.23 and 0.63 mm. were noted, and with Tube II, a 2-mm. decrease. The initial pressures varied from 0.75 to 5 mm. The ratio  $(He_{abs}/Pt \text{ used})$  could be taken as an index of

the extent of compd. formation. The vol. of He consumed per g. of Pt was 14–34 cc.

**The action of helium on platinum.** H. DAMIANOVICH AND J. J. TRILLAT. *Compt. rend.* 188, 991–2 (1929); cf. *C. A.* 23, 1537.—X-ray powder diagrams were made of Pt prep'd. by elec. discharge in He and in air and of Pt so prep'd. after heating. The Debye-Scherrer rings showed a particle size varying with the method of prep'n. In Pt prep'd. in He, a very fine extra ring indicated a small proportion of a new form of Pt or of some kind of Pt-He combination.

**Thermal expansion of tantalum.** PETER HEDNERT. *Bur. Standards J. Research* 2, 887–96 (1929).—Measurements were made on the linear expansion of three samples of worked and annealed Ta over various temp. ranges between  $-190^{\circ}$  and  $500^{\circ}$  with app. previously described (*C. A.* 22, 750, 1313). Worked Ta expanded practically the same as annealed Ta. The most probable second-degree equation for the expansion of Ta between  $20^{\circ}$  and  $500^{\circ}$  is  $L_t = L_0[1 + (6.59t + 0.00008t^2)10^{-6}]$ . The coeff. of expansion increases slightly with temp. Between  $20^{\circ}$  and  $100^{\circ}$  the av. coeff. of expansion is  $6.6 \times 10^{-6}$  per degree C.

**Solid helium at high temperatures.** F. SIMON. Univ. Berlin. *Naturwissenschaften* 17, 256 (1929).—Recently it has been shown (*C. A.* 23, 2640) that the curve of m. p. vs. pressure for He does not approach lower temps. or reach a limit but rises continuously according to the relation  $\log(a + p) = c \log T + b$ . Exptly. it was to be found whether this curve is bounded by a crit. point of cryst. and liquid phases. Work of S. (*C. A.* 23, 2860) comprises the data from  $12^{\circ}$  to  $20^{\circ}$  abs., represented well by the equation. In order to go to higher pressures, the plugging of a capillary was used as the criterion of solidification; 14 points of the m.-p. curve between  $20.4^{\circ}$  and  $32.4^{\circ}$  abs. were det'd. The accuracy was 1.5%. The pressures corresponding to m. ps. of  $1^{\circ}$ ,  $4^{\circ}$ ,  $8^{\circ}$ ,  $12^{\circ}$ ,  $16^{\circ}$ ,  $20^{\circ}$ ,  $24^{\circ}$ ,  $28^{\circ}$  and  $32^{\circ}$  abs. are, resp. (Keesom values), 26, 131, 425, 813, 1270, 1800, 2380, 3010 and 3690 kg. per sq. cm. The pressure range is being further extended; if no crit. point appears, the pressure at  $80^{\circ}$  abs. should be 15,000, at room temp. 100,000 kg. per sq. cm. It is significant that for He solidification is possible at a temp. sixfold the ordinary crit. temp. The greatest excess previously known is 20% for  $\text{CO}_2$ . The importance of this for the knowledge of the condition of elements in the interior of stars is evident.

**Quantum mechanics and chemical linkage.** F. HUND. *Z. Elektrochem.* 34, 437–42 (1928).—A summarizing review.

**The different types of chemical union.** H. G. GRIMM. *Z. Elektrochem.* 34, 430–7 (1928).—A summarizing review.

**The determination of the forces of attraction from chemical equilibria.** RICHARD LORENZ. *Z. physik. Chem., Abt. A., Haber Bd.*, 139, 1–11 (1928).—In his book "The law of chem. mass action" (cf. *C. A.* 22, 1530) L. has developed a new equation for condensed systems, calcd. with the thermodynamic potential and the equation of van der Waals. The new equation is applied to a series of chem. equil. and a better insight into the forces of attraction between mols. and atoms is obtained.

**The different magnetic states of an ion.** G. FOEX. *Trans. Am. Electrochem. Soc.* 55 (preprint) 5 pp. (1929).—The  $\text{Fe}^{++}$  ion occurs in 3 distinct magnetic states; it is difficult to account for the differences between the 3 magneton values. Measurements made with different samples of  $\text{NiSO}_4 \cdot 7\text{H}_2\text{O}$  have always given the value = 16 magnetons. The Co ion value is 25 magnetons. The dehydrated  $\text{CoSO}_4$  put into soln. gave a value of 26, but after long standing the value decreased to 25. However, when a Co salt ( $\text{CoCl}_2$ ) is put into soln. in alc., the value for the Co ion is only 23 magnetons. In conc'd.  $\text{H}_2\text{SO}_4$  the value is 25.66. Upon crystallizing  $\text{CoCl}_2$  out of soln. in alc., the value shifts from 23 (soln.) to 26 (crystal). It follows that the ion in soln. is not the same as the ion in crystal. It seems probable that the different magnetic states correspond to a different structure in the outer layer of electrons in the atom. It is to be expected that other properties of the ion, which depend on that outer layer, will change with the changes which occur in this layer.

**Molecular form and dipolar moment.** WALTER HÜCKEL. *Z. physik. Chem., Abt. B*, 2, 451–7 (1929).—The existence of dipolar moments in compds. of the type  $\text{Ca}_4$  is not contradictory to the ideas of classical stereochemistry and cannot be used as an argument for the pyramidal form of such mols. The arguments are based on the equivalence and freedom of rotation of the groups attached to the C atom.

**The electric moment of primary alcohols.** P. N. GHOSH. *Nature* 123, 413–14 (1929).—The primary alcs. have very nearly the same dipole moment  $\mu = 1.63 \times 10^{-18}$ . The secondary alcs. have a different elec. moment of roughly  $1.78 \times 10^{-18}$ .

**Solution velocity of substances being reduced to fragments.** WAWRZYNIEC

JACEK. *Roczniki Chem.* 9, 19-38(38-40 French)(1929); cf. *C. A.* 22, 2096.—The soln. consists of two simultaneous processes: (a) the penetration of the constituent fragments of substances (atoms, ions, molecules, etc.) in the solvent and (b) their simultaneous deposition from the soln. on the surface of the solid substances. The velocity of the first process is in the simplest case const.; that of (b) is proportional to the concn. of the soln. at a given moment. If  $\nu'$  is the no. of constituent fragments detaching at a given moment from the surface unit and penetrating the soln. in the time unit, and  $n$  the no. of fragments already dissolved at the time  $t$ , then the no. of the fragments  $dn$  actually dissolving in the interval of time  $dt$  from the surface unit is expressed by (I)  $dn = [\nu' - K'(n/v)]dt$ , where  $v$  is the velocity of soln. and  $K'$  the proportionality factor. At the satn. point  $dn/dt = 0$ ,  $\nu' = K'(N/v)$  (II),  $N/v$  denoting the concn. of the satd. soln. If  $P$  is the surface of the dissolving fragments, then according to I and II  $dn/dt = (P/\text{surface unit})(K'/v)(N - n)$  and (III)  $dn/dt = (P/\text{surface unit})(\nu'/N)(N - n)$ . If the surface  $P$  is variable during the processes, the last equation can be transformed, replacing the fragments of  $N$  by spheres; thus  $N = (4/3)\pi a_1^3(\delta/m)$  where  $a_1$  is the radius of the sphere,  $\delta$  its density,  $m$  the mass of the fragments. Similarly,  $n = (4/3)\pi(a^3 - r^3)(\delta/m)$ , where  $a$  is the radius of the spheres of fragments going into soln. at  $t = 0$  and  $r$  is the radius of the sphere at the time  $t$ . Finally  $\nu' = \rho' \times \text{surface unit} \times (\delta/m)$  is deduced,  $\rho'$  being the thickness of the layer of dissolving fragments in the unit of time if the solvent is in excess, for in this case only can the process (a) take place. On substitution in place of III (IV)— $dr/dt = (P/4\pi r^2)(\rho'/a_1^3)(C - r^3)$  or more simply  $c = (a_1^3 - a^3)$  (cf. *C. A.* 22, 2095).  $P$  is the variable surface value of the fragments being dissolved. The equation IV is applicable even if  $P$  expresses the sum of surfaces of small fragments which are dissolved. These fragments were cubes in the case of NaCl. Here they are of equal size and, therefore,  $P/4r^2\pi = \text{const.}$   $\rho'$  is the actual velocity const. of soln. (of dimensions  $L/T$ ). For the crystals  $\rho'$  is a variable quantity on account of their anisotropy and it is necessary to take an average value in this case. J. K.

**Prism refractometry and certain goniometrical requirements for precision.** L. W. TILTON. *Bur. Standards J. Research* 2, 909-30(1929).—From a crit. review of sixth-decimal prism refractometry and refraction methods it is concluded that the method of min. deviation is the most sensitive for solid or liquid media. The use of four or more equidistant microscopes for scale observations, in which accidental and periodical errors are eliminated and an accuracy of  $\pm 1$  unit in the sixth decimal place is obtained even on uncalibrated circles, is prescribed. Micrometer errors and variable residual mech. strains in the goniometer are discussed. H. W. WALKER

**The crystal structure of some binary compounds of the platinum metals.** L. THOMASSEN. *Z. physik. Chem., Abt. B*, 2, 349-79(1929); cf. *C. A.* 22, 4289.—X-ray powder-method photographs reveal a pyrites structure for  $\text{OsTe}_2$  with  $a = 6.369$  A. U.,  $\text{OsSe}_2$  with  $a = 5.933$  A. U.,  $\text{RuTe}_2$  with  $a = 6.360$  A. U.,  $\text{RuSe}_2$  with  $a = 5.921$  A. U. and  $\text{PtSb}_2$  with  $a = 6.428$ . It is concluded that  $\text{PdTe}_2$  with  $a = 4.028$  and  $c = 5.118$  A. U.,  $\text{PtTe}_2$  with  $a = 4.010$  and  $c = 5.201$  A. U.,  $\text{PtSe}_2$  with  $a = 3.724$  and  $c = 5.062$  A. U., and  $\text{PtSb}_2$  with  $a = 3.537$  and  $c = 5.019$  A. U., possess the  $\text{CdI}_2$  type of structure.  $\text{PdTe}$  has the Ni arsenide structure with  $a = 4.127$  and  $c = 5.663$  A. U. Attempts to prep.  $\text{OsTe}$ ,  $\text{OsSe}$ ,  $\text{RuTe}$  and  $\text{RuSe}$  were unsuccessful. Systems of these compns. were mixts of the corresponding binary compd. and free metal. These binary compds. together with the corresponding Ir and Rh derivatives were found to be slightly para- or diamagnetic but not ferromagnetic. H. W. WALKER

**The numerical determination of the speed of crystallization.** HANS SCHWERDT-FEGER. *Chem. App.* 16, 45-7, 82-5(1929).—A mathematical paper designed solely for lab. use, and in no sense a contribution to the theory of crystal structure. J. H. MOORE

**Chemical valency considered as an electrostatic phenomenon.** A. E. VAN ARKEL AND J. H. DEBOER. *Chem. Weekblad* 26, 282-6(1929); cf. *C. A.* 23, 3135. G. C. Berthelot's principle of maximum work from the molecular kinetic point of view.

N. V. TANTZOV. *J. Russ. Phys.-Chem. Soc.* 60, 361-8(1928). J. KUČERA

**A new equation of state for fluids.** JAMES A. BEATTIE AND OSCAR C. BRIDGMAN. *Proc. Am. Acad. Arts Sci.* 63, 229-308(1928); cf. *C. A.* 23, 1032.—On the basis of the kinetic theory, the following equation of state is derived:  $p = [RT(1 - \epsilon)/V^2](V - B) - (A/V^2)$ , in which  $A = A_0[1 - (a/V)]$ ,  $B = B_0[1 - (b/V)]$  and  $\epsilon = c/VT^2$ . In the derivation, it is assumed that the kinetic and cohesive pressures can be considered separately, and, with respect to the law of force between mols., it is assumed only that the force diminishes rapidly with distance. Among the advantages of the proposed equation are: (1) the ease and uniqueness of the detns. of the values of the consts. from measurements of pressure, vol., and temp.; (2) simplicity in mathematical form; (3)

applicability over wide ranges of temp. and density; (4) provision for extension of the vol. and temp. functions  $A$ ,  $B$  and  $c$  without change in the general form of the equation. A critical study of the equation is made from the point of view of the exptl. facts regarding the isotherms and isometrics of a gas. The method of detg. the consts. from exptl. data is illustrated,  $O_2$  being used as an example. A critical bibliography is given of the compressibility data for He, Ne, Ar,  $H_2$ ,  $N_2$ ,  $O_2$ ,  $CO_2$ ,  $CH_4$  and  $(C_2H_5)_2O$ . Detailed comparisons are made of observed pressures with pressure calcd. from the equation. The av. deviation at 1777 points of comparison for the ten gases studied is 0.18%. The use of the equation in thermodynamic calcs. is discussed. MERRILL W. SEYMOUR

**The fundamental equation in the kinetic theory of liquids and gases.** D. ENSKOG. *Arkiv. Mat. Astron. Fysik.* 21A, No. 13, 28 pp. (1928).—By using van der Waals' assumption concerning the mol., complicated mathematical reasoning can be avoided, although many difficulties still remain. The term contg. the vol. is estd. from an av. of a great no. of identical systems. A further difficulty met with is the no. of impacts. A new derivation for the transport equation is given which includes the no. of impacts. The new definition agrees with earlier work of the author. The equation applies satisfactorily to liquids. Boltzmann's fundamental equation for dil. gases has also been remodeled. The article is largely mathematical. RAYMOND H. LAMBERT

**The determination of gas density with the vacuum balance. III. The electromagnetic balance for laboratory use.** ALFRED STOCK. *Z. physik. Chem., Abt. A*, Haber Bd., 139, 47–52 (1928); cf. *C. A.* 21, 679.—Details of construction and method of operation are given. The balance permits a quick detn. with an accuracy of from one to several tenths of one percent. It may also be used for the identification of gases, for the analysis of gas mixts. (also flue gas), etc. EMIL KLARMANN

**High-vacuum technic.** C. T. KNIPP. *Trans. Illinois Acad. Sci.* 21, 212–8 (1928).—Diagrams of various types of Hg vapor pumps are given. The quant. study of the speed of exhaustion of these pumps, and curves showing this behavior are discussed. L. L. QUILL

**Specific heat of gases in combustion technic.** HOLGER A. LUNDBERG. *Jernkontorets Ann.* 82, 217–46 (1927); *Ingeniors-Vetenskapsakad. Hand* 58, 1–32.—A survey of data concerning sp. heat of  $CO_2$ ,  $N_2$ ,  $O_2$ , CO,  $CH_4$  and steam. Schacks' formulas (Mitteilungen der Wärimestelle Düsseldorf, No. 87, 1926) are used for calcn. of theoretical combustion temp.

**Thermal diffusion of rare constituents in gas mixtures.** SIDNEY CHAPMAN. *Phil. Mag* [7], 7, 1–16 (1929).—Thermal diffusion in gases is capable of producing concn. gradients of the same order of magnitude as are found in the Soret effect in many liquid solns. The prospect of arriving at even an approx. correct theory, where pure thermal diffusion is the main cause, is at present rather remote. The law of force between He mol. and Rn is detd. L. H. REYERSON

**The thermal properties of carbon dioxide in the gaseous, liquid, and solid states.** R. PLANK and J. KUPRIANOFF. *Z. ges. Kälte-Ind.* 36, 41–8 (1929).—See *C. A.* 23, 2644. F. D. ROSSINI

**Flow of gases from orifices.** O. WALGER. *Arch. Wärmewirt.* 9, 368–9 (1928).—The thermodynamic correction factor which takes account of compressibility in the flow of gases from orifices is very nearly a linear function of the pressure-drop ratio for any given value of the sp. heat ratio. This makes possible a convenient approximation formula which is accurate to 0.5%. ERNEST W. THIELE

**Viscosity of mixtures of rare gases.** I. A. G. NASINI and C. ROSSI. *Gazz. chim. ital.* 58, 898–912 (1928); cf. *C. A.* 23, 1033.—The kinetic theory of viscosity deals with monatomic gases, and so the rare gases are of special interest in this connection, not only because they are monatomic but also because the ratio of their mass to viscosity varies in a way which lends itself particularly well to theoretical deductions. New viscosity measurements were therefore made, mixts. of He and Kr and of He and Ne being chosen. The viscometer and technic were essentially the same as already described in previous work. The viscosity-concn. curve of the He-Kr mixts. showed a max. of the already known character, whereas there was no max. for Kr-Ne mixts. The data obtained for these mixts. agree well with those calcd. by the formula of Pulu. The formula of Kuenen (cf. *Die Eigenschaften der Gasen*, Leipzig, 1919) and its relation to the const. of mol. attraction is discussed. C. C. DAVIS

**Viscosity of gaseous mixtures.** I. A. G. NASINI and C. ROSSI. *Gazz. chim. ital.* 58, 912–21 (1929); cf. preceding abstr.—Mathematical. Analysis of the formula of Pulu. allows the calcn. of the temp. limits between which it is possible for maxima to exist in the curves showing the viscosities of gaseous mixts. as a function of the proportions of the components. Deductions show that the max. can at times be proved only be-

tween 2 well-defined limits of temp., whereas in other cases the max. may exist and yet not be established. The results which are obtained agree well with exptl. data

C. C. DAVIS

The state called "Sama-Zustand." ERIC A. HOLM. *Compt. rend.* 187, 531-7 (1928).—The Sama-Zustand is defined as a state in which there is temp. difference and yet complete equil. (no thermal flow). With gases at low pressure such a state is reached in a gravitational field, the force downward counterbalancing a higher temp. in the lower part of the gas. The temp. gradient is of the order of  $13 \times 10^{-6}$  degree/cm. at pressures of  $10^{-4}$  mm. This effect has been detected by the use of a microbalance.

F. R. BICHOWSKY

Electric conduction of salt vapors. HJ. V. BROTHÉRUS. *Ann. acad. sci. Fennicae* 28A, No. 6, 1-20 (1928).—Elec. conduction of vapors of LiI and CdI<sub>2</sub> was studied. A const. and homogeneous stream of vapor was obtained by inserting a capillary tube and a glass screen between the vaporization chamber and the electrodes. Upon applying the potential the current strength decreases rapidly and after a few mins. becomes const. Data and curves are given showing the effect of varying pressure, temp. and voltage on the time before const. current is obtained. The time is greater at the higher pressures, higher voltages and lower temps. The current decrease is thought to be due to an initial thermal ionic equil., which is displaced to a new value upon closing the circuit. Data and curves are given for CdI<sub>2</sub> vapor showing the current increase with temp. from 400° to 550°. The no. of mol. impacts per sec. was calcd. and found to be too few to attribute the ionization phenomena to simple inelastic impacts of neutral unexcited mols. The Saha equation,  $2 \log (i_1/i_2) = -5048 V[(1/T_1) - (1/T_2)] + 1.5 \log (T_1/T_2)$ , gives 5.4 as the ionization potential,  $V$ , for CdI<sub>2</sub> vapor;  $i_1$  and  $i_2$  are the c. ds. at the resp. temps.  $T_1$  and  $T_2$ .

J. E. SNYDER

The conductivity of insulating liquids and the electromotive force of galvanic chains with those liquids determined by an electrostatic method. H. G. BOS. *Physica* 9, 128-41 (1929).—For the detn. of the cond. of insulating fluids a measuring vessel was used (tinned beaker  $50 \times 72$  mm.) with brass rod ( $7 \times 50$  mm.) as center electrode. The elec. app. was ventilated with warm, dust-free air or gas to eliminate moisture leakage effects. The beaker electrode was held at a const. potential. The rise in potential of the rod electrode, initially zero, was detd. by electrometer; it indicates the cond. The sign of the potential used was repeatedly reversed. At any moment the electrometer potential  $V$  is detd. by  $dV/dt = [q_1 - k(V + E_0 - B) - (KV + L)] / (cD + C_0 + C_b)$  in which  $q_1$  is the "primary effect," i. e., elec. charges from gas or liquid flow friction, space charges, etc.,  $k$  the cond. of the liquid,  $V$  and  $B$ , resp., are potentials of rod and beaker,  $E_0$  is the e. m. f. of the rod-liquid-beaker galvanic element,  $KV + L$  the sum of all elec. fluxes outside the measuring vessel,  $D$  the dielec. const. of the liquid,  $c$  the capacity of the vessel in vacuo, and  $C_0$  and  $C_b$  are capacities of app. and addnl. measured capacity. A no. of equations are derived for the detns. with blank expts. of various consts., part of which can safely be neglected. The limiting value of  $V_1$  is found to be  $\Delta = [q_1 - k(E_0 - B) - L] / (k + K)$  and of  $k + K = (cD + C_0 + C_b) / t_1 \ln (1/a)$  if  $t_1$  is the time necessary to make  $\Delta - V_1$  equal to  $a(\Delta - V_0)$ . A commercial gasoline was used for control of the theory. The potential of the electrometer was read every 5 secs. For the cond.  $k$  was found  $3.0 \times 10^{-12}$  mho, sp. cond.  $\lambda = 1.9 \times 10^{-14}$  mho, the value of  $E_0$  was  $-0.20$ . No polarization of the electrodes was observed, Ohm's law being followed by the element.

B. J. C. VAN DER HOEVEN

A capillary-tube method for the simultaneous determination of surface tension and of density. ALLAN FERGUSON and J. A. HAKES. *Proc. Phys. Soc. London* 41, 214-23 (1929).—A capillary tube of radius  $r$  is immersed vertically to a depth  $h_1$  in the liquid of d.  $\rho_1$  under test. The pressure  $gph$  required to force the meniscus down to the lower end of the capillary and hold it there is measured. If  $h_1$ , and consequently  $h$ , be varied, a plot of  $ph$  against  $h_1 - (r/3)$  gives a straight line from whose slope and intercept the surface tension and the d. of the liquid may be inferred. Two cuts of the app., 2 graphs and 3 tables of results are given and the theory of the method is treated mathematically, with references.

J. H. MOORE

The process of adsorption. II. W. KÄLBERRER and C. SCHUSTER. *Z. physik. Chem., Abt. A*, 141, 270-96 (1929); cf. *C. A.* 23, 1036.—The magnitude and properties of the interface of silicic acid gel were studied by measurements of the isotherms and heats of adsorption of gases. The heat of adsorption of A detd. experimentally agrees with that calcd. from the isotherms. It is 2500 to 3200 cal. at 0°, the higher values being for the more completely outgassed gels. The isotherms for CO<sub>2</sub> are sometimes linear in the lower range of pressures (indicating adsorption on plane surfaces), sometimes have a steep initial portion (indicating active areas in the gel), and sometimes

have convex curvature (indicating capillary condensation). These effects may be superimposed upon each other. The heat of adsorption of  $\text{CO}_2$  on plane surfaces is 7200 cal. at  $0^\circ$ . The heat of adsorption of  $\text{N}_2$  at  $0^\circ$  is 3000 cal., but varies with the method of prepg. the gel. For  $\text{C}_2\text{H}_4$  the heat of adsorption is 7300–7700 cal. The adsorption vol. is a function of the heat of adsorption, being smaller the higher the heat of adsorption. The interface of silicic acid gel is  $100 \times 10^4$  sq. cm. per g.

F. L. BROWNE

Calculated conceptions from viscosity in the realm of plastic flow. WOLFGANG OSTWALD. *Kolloid-Z.* 47, 176–87(1929).—The theoretical equation for viscosity and pressure by Blair (*C. A.* 23, 1798) is not generally applicable because it fails to agree with published data. Since a well-defined yield value is often present, the curve for low rates of flow is necessarily not linear so that Blair's linear relationship would apply only to some middle portion of the curve. Such colloids as clays may obey the formula. Data obtained from various sources and with quite different instruments are compared and found to be identical with calcd. values obtained from the author's formula.

RAYMOND H. LAMBERT

Adsorption at the surface of binary liquid mixtures. R. S. BRADLEY. *Phil. Mag.* [7], 7, 142–5(1929).—Too much attention has been paid to the adsorption of one constituent in binary liquid mixts. without considering the changes in the surface concn. of the other. Rideal and Schofield (cf. *C. A.* 19, 3397) were not dealing with surface concn. of alc. in alc. mixts. but with  $\Gamma_1 - \Gamma_2(N_1/N_2)$  where  $\Gamma_1, \Gamma_2$  are the Gibbs surface excesses and  $N_1, N_2$  the mol. fraction of alc. and water, resp. From the measurements of Frumkin (cf. *C. A.* 19, 1799) an expression is deduced which permits calcn. of the surface excesses for the alc.-water mixts. When surface concn. is plotted against mol. fractions a max. is found in the curve for each constituent. The calcn. is checked by plotting the surface concn. of alc. against that of water. A straight line results.

L. H. REYERSON

The influence of adsorbed films on rates of evaporation. RONALD P. BELL. *J. Phys. Chem.* 33, 99–117(1929).—Measurements were made of the rate of evapn. of Cl from its soln. in  $\text{CCl}_4$  under different conditions of Cl concn. and velocity of flow. The influence on the evapn. rate of  $\text{CCl}_3\text{COOH}$  dissolved in  $\text{CCl}_4$  was measured and the decreased rate of evapn. attributed to surface adsorption. From the results it is deduced that a satd. surface film, presumably monomol., is formed at all concns. greater than about 1.4 g. of acid per 100 g. of soln. This value is in agreement with that obtained by the application of Gibbs' adsorption equation to surface tension measurements of  $\text{CCl}_3\text{COOH}$  solns. The author suggests that the measurement of rates of evapn. may prove of general utility in the investigation of adsorption from soln.

P. T. NEWSOME

Capillarity. X. Further formulation of capillary structure. KARL SCHULTZE. *Kolloid-Z.* 47, 310–3(1929).—A theoretical discussion of the influence of the capillary cross section on the flow of fluids by the aid of a novel system of formulation. L. F. M.

The influence of capillary size on the flow of colloidal solutions in the capillary viscometer. W. HALLER AND V. TRAKAS. *Kolloid-Z.* 47, 304–10(1929).—A critical no. characteristic of the structure viscosity, was detd. for the flow of colloidal solns. similar to the Reynolds no. for turbulence. The exptl. results confirmed the theory. On the basis of certain assumptions, similar relations for the whole structure viscosity range may be detd. Certain anomalous viscosities of colloidal solns. may be explained by means of the relation between viscosity and turbulence. The equation of A. de Waele Wo. Ostwald was altered so that the const. are independent of dimensions of app. and are functions of the material only.

L. F. MAREK

Rigidity in weak clay suspensions. R. K. SCHOFIELD AND B. A. KEEN. *Nature* 123, 492 3(1929).—In the course of work necessitating the purification of quantities of the smallest soil particles (the so-called clay fraction) a striking phenomenon was observed during the flocculation and sedimentation of the material in dil. HCl. When the concn. of the suspension exceeds a crit. value a no. of sharp ramifying fissures develop contg. clear liquid. The density of this being less than that of the surrounding clay-laden liquid a circulation is set up, clear liquid rising through the fissures while the remainder sinks. Near the bottom of the vessel the fissures tend to close, and to enlarge progressively towards the top of the column into conical chimneys. There is no doubt that the suspension has acquired rigidity. The surface of the settling suspension has the appearance of a region covered with many craters. GEO. GLOCKLER

The colloids and industry. H. PERPEROT. *Science & ind.* 13, 177–80(1929).—A study of colloidal substances, their chem. constitution, their prepn. and some of their

properties. Flocculation and coagulation, osmosis, dialysis, flotation and ultrafiltration are discussed.

**Dispersion and size of particles.** REINHOLD FÜRTH. *Kolloidchem. Beihefte* 28, 293-5(1929).—A review of the conceptions of the size of particles in relation to their properties.

**Chemical combination and dispersion of crystalline particles.** WO. OSTWALD AND A. VON BUZÁGH. *Kolloid-Z.* 47, 314-23(1929).—The stereochem. combination of the elementary micelle of crystals as shown by x-rays is recognizably different from the stoichiometric combination of macrocrystals. The first combination must result from the growth of the particles themselves. The transition for the growth of particle size was detd. and plotted for a series of lattice types. It is shown that the convergence of the stereochem. and stoichiometric combinations occurs in crystals of the rock salt type at  $1-2 \times 10^3$  elementary cells arranged in a hexahedron; in fluorite at  $4-5 \times 10^4$ ; in the others at about  $10^5$  elementary cells. The edge of these first crystallites from practically stoichiometrical combination varies between  $10^{-6}$  and  $10^{-5}$  cm. This is the typical colloidal dimension. Also the not stoichiometrically related surface tension or adsorption phenomena of crystals may be assumed of the same order of magnitude. From this it follows that, theoretically, the combination of colloidal particles in sols or highly dispersed ppts. can vary with the particle size. As examples, a cryst.  $\text{CaF}_2$  sol formed by condensation at high dispersions is Ca-richer than at lower; an old  $\text{CaF}_2$  ppt. is altered by recrystn.; changes in H-ion concn. occur on standing, etc. By use of the Smekal theory it is shown that the lattice structures postulated by this author are essentially identical with crystallites which have reached stoichiometric relations. The Smekal elements are of colloidal dimensions. The change from stereochem. to stoichiometric combination is apparently related to a peculiar stabilization of the crystallites concerned.

**Lyophilic colloids. I. Osmotic pressure and viscosity measurements of rubber solutions.** H. KROEFELIN. *Kolloid-Z.* 47, 294-304(1929).—The expt. was carried out on the cold ether ext. of acetone-extd. crepe rubber. Through measurement of the osmotic pressure at  $11^\circ$  and  $40^\circ$  the vapor pressure of rubber solns. and then temp. coeff. were detd. From the values the heat of diln. was calcd. From the simplified van der Waal's equation the micelle wt. was detd. as 200,000. The present exptl. work may be presented by use of Freundlich's swelling equation, as Wo. Ostwald has shown for the "sol-swelling" of other systems. For the evaluation of viscosity measurements, the mean value of the velocity of flow of a stream through a capillary was used. From the results it is shown that the apparent viscosity is a function of the mean velocity of flow. Measurements in different capillaries gave the same value for the apparent viscosity, when the mean value of the velocity is selected as the independent variable. The apparent viscosity is a linear function of the log of the velocity with all rubber solns. used. No simple relation was found to exist between viscosity and osmotic pressure.

**The stability of colloids. I. Lyophobic colloids.** H. R. KRUYT. *Rev. gén. colloides* 6, 118-33(1928).—This is a general review of the history and properties of lyophobic colloids, as developed by students of the subject from the time of Thomas Graham to the present time. **II. Lyophilic colloids.** *Ibid* 149-60.—This is a general review.

**A method for investigating the appearance of coagulation and peptization.** A. V. BUZÁGH. *Kolloid-Z.* 47, 370-2(1929).—By counting the pieces of pulverized glass which settle from a suspension in  $\text{H}_2\text{O}$ , it was shown that the addn. of increasing quantities of sodium oleate and NaOH has a peptizing effect on the pulverized glass, while  $\text{KCl}$ ,  $\text{BaCl}_2$  and  $\text{ThCl}_4$  have coagulating effects. A max. coagulating effect is reached with  $\text{ThCl}_4$  at the isoelec. point.

**The behavior of hydrotropic mixtures.** A. NOLL. *Chem. tech. Fabr.* 26, 43-6, 47-50(1929).—The soly. and emulsifying property are given for many mixts. in which the following substances were used in varying proportions:  $\text{H}_2\text{O}$ , hexalin, methylhexalin, majamin, soaps, terpineol, castor oil, savonette oil, fusel oil, rosin, Nekal A, Nekal BX, Idrapid and naphthalene salt.

**Emulsions and the effect of hydrogen-ion concentration on their stability.** JOHN C. KRANTZ, JR., AND NEIL GORDON. *Colloid Symposium Monograph* 6, 173-206(1928).—Oil-in-water emulsions are given by Na oleate, arabic acid; arabates of Na, Mg and Fe; valerates of  $\text{NH}_4$  and Na; Na gluconate, galactonate, dihydroxystearate, salicylate and gallate. Water-in-oil emulsions are given by oleates of Mg, Ca, Co(ous), Mg and Al; Mg and Zn valerates; dihydroxystearate. Pb arabate would not serve, and the following were amphoteric: Ca gluconate, Cd galactonate, Ca salicylate

and gallate. In emulsions of vegetable or mineral oil with acacia, greatest stability exists when the  $p_H$  of the external phase is between 2 and 10. With tragacanth, the  $p_H$  range is 1.9 to 2.3. Greatest stability for acacia,  $p_H$  4.11 to 4.28; for tragacanth, about 2.5. Particle size, surface tension, interfacial tension and viscosity were detd. at various  $p_H$ , which affects particle size and viscosity in tragacanth emulsions, but not in acacia emulsions, except that particle size increased in the latter with  $p_H$  over 7. "There are indications of Fischer's hydrate theory being substantiated in emulsions prepd. with tragacanth." Olive oil gives a more stable emulsion with Mg oleate than does mineral oil, the most stable emulsion range being  $p_H$  11–12.5, with an extremely unstable range at  $p_H$  2.5. Surface tension of water-in-oil emulsions is unaffected by  $p_H$  changes of the internal phase; unstable emulsions had lower viscosity than stable ones; particle-size variations, up to  $30\mu$  average, did not alter stability. J. A.

**Colloidal platinum. V. The coagulation by electrolytes in acid solution.** STUART W. PENNYCUICK. *J. Chem. Soc.* 1929, 618–23; cf. C. A. 22, 4306.—The addn. of a salt causes cationic interchange at the surface with the liberation of the free acid of the salt. In agreement with Pauli and Schmidt, P. shows that this interchange leads to coagulation of the colloid. The change is followed by conductance measurements. In acid solns. cationic interchange is partial. The coagulum contains some of the surface acid. Highly hydrolyzed salts of strong acids show the symptoms of acid coagulation. As the  $p_H$  is lowered, the coagulating value of the salt increases. VI. The behavior of platinum sols in basic solution. *Ibid* 623–33.—By titrating Pt sols with the hydroxides of Na and Ba, P. concludes that 25% of the surface of a colloidal Pt sol consists of hexahydroxyplatinic acid. The rest of the surface is composed of lower, less active acid oxides which are too weak to form acids with water but form salts with bases. These conclusions enable P. to explain the different actions of NaOH and Ba(OH)<sub>2</sub>. P. also shows that Pt sols are reversible if the correct conditions are obtained. The pptd. particles obtained by freezing a sol are not peptized by washing or warming with NaOH soln. F. W. LAIRD

**Bright-colored silver sols by use of hydrogen peroxide. I. ERNST WIRGEL.** *Kolloid-Z.* 47, 323–5(1929).—A method is described for the prepn. of Ag sols from AgNO<sub>3</sub> solns. by the use of alk. dextrin solns. The Ag sols may then be colored from an orange-yellow, to shades of red, to shades of violet and blue, to colorless by the addn. of varying amts. of a 9% soln. of H<sub>2</sub>O<sub>2</sub>. Results are tabulated with a description of the ultra-microscopic appearance of the sols. L. F. MAREK

**Equilibrium in the system: colloidal iron hydroxide-hydrochloric acid-water.** ERICH HEYMANN. *Kolloid-Z.* 47, 325–30(1929); cf. C. A. 23, 1797.—The reaction: colloidal Fe(OH)<sub>3</sub> + 3HCl → FeCl<sub>3</sub> + 3H<sub>2</sub>O was studied. For const. concn. of HCl a higher concn. of Fe(OH)<sub>3</sub> gave a higher concn. of FeCl<sub>3</sub>. The ratio [HCl]<sup>3</sup>/[FeCl<sub>3</sub>] is only fairly const. In accordance with Herzfeld's findings it is assumed that the reaction occurs throughout the particle rather than on the surface only. The equil. is influenced by the degree of dispersion of the hydrolysis products, in that coarsely dispersed Fe(OH)<sub>3</sub> is in equil. with a lower concn. of FeCl<sub>3</sub> than is finely dispersed Fe(OH)<sub>3</sub>. The degree of dispersion varies with the age of the sol. Micelles of varying chem. compn. were obtained by varying the age of the sol or by varying the procedure at equil. conditions. An explanation is offered based on the work of Wintgen and Biltz. L. F. MAREK

**Colloidal solutions of alumina and of chromium oxide and their desiccation.** PAUL BARY AND JOSÉ V. RUBIO. *Compt. rend.* 188, 625–6(1929).—Colloidal solns. prepd. by the dialysis of Al(OAc)<sub>3</sub> and of CrCl<sub>3</sub> were allowed to evapor. Concentric rings alternately colorless and colored were formed due to the lamellar arrangement of the dried film. L. B. MILLER

**Method of ebullioscopic and tonometric researches.** WOJCIECH ŚWIĘTOSŁAWSKI. *Roczniki Chem.* 9, 266–307(307–8 French)(1929).—Several simple and differential ebullioscopes and the methods of using them are described. They were used in the following physicochem. researches: graduation and comparison of thermometers, verification of the thermometric scales, tonometrical measurements, detns. of coeff.  $dp/dT$  and heat of vaporization, of b. ps. of liquids or their mixts., of the coeff. of variation of the soly. with temp., of esterification const. in the gaseous and liquid phase  $K_p$  and  $K_l$ , of the velocity const.  $K$ , and in the investigation of azeotropic mixts. and displacement of the max. or min. point with pressure. An app. for ebullioscopic researches allowing pressures up to 20–30 atm. is described. J. KUČERA

**Ebullioscopic studies of mixtures of salt solutions.** GRZEGORZ PRONIEWSKI. *Roczniki Chem.* 9, 115–28(129–30, French)(1929).—Bourion and Rouyer's data concerning the deviations of b. ps. of mixts. of salt solns. were verified and their method (C. A.

21, 3009) was applied to saline solns. in which the cations were alkali metals and most metals of the second group and the anion was  $\text{Cl}^-$ . The mixts. of alkali and alk. earth chlorides with the chlorides of Zn, Cd and Hg show particular lowering of b. ps. The max. of the deviation curves for the mixts. with  $\text{CdCl}_2$  and  $\text{ZnCl}_2$  are at the point corresponding to 60% of alkali or alk. earth chloride in the mixt.; the position of max. practically does not vary when the solns. cease to be equimol. and their concns. become two, three or four times as great. By using the same method for the mixts. of alkali chlorides with water (and also alk. earth chlorides), a curve is obtained with a max. close to 50% of water content. On addn. of water to the solns. of  $\text{CdCl}_2$ ,  $\text{ZnCl}_2$  and  $\text{HgCl}_2$ , deviation curves are obtained different from the preceding ones, deviations being positive or negative depending upon the kind of chloride or concn. By comparing the curves it can be seen that the deviation of b. p. depends principally on the process taking place during the mixing of the solns. of alkali chlorides (and alk. earth chlorides) with water. This is the cause of the deviation and the influence of  $\text{CdCl}_2$ ,  $\text{ZnCl}_2$  and  $\text{HgCl}_2$  consists in a considerable increase of deviations, due to the mixing of solns. of  $\text{MCl}$  with water, and in insignificant displacement of max. Therefore, conclusions are drawn that the deviation of b. ps. and the position of max. observed by mixing  $\text{CdCl}_2$ ,  $\text{ZnCl}_2$  and  $\text{HgCl}_2$  solns. with  $\text{KCl}$  or  $\text{CaCl}_2$  solns. cannot serve as an indication for detg. the compn. of double salts as Bourion and Rouyer believe. J. KUČERA

The boiling temperatures of the homologous series. BORIS NEKRASOV. *Z. physik. Chem., Abt. A*, 140, 342-54 (1929).—If it is assumed that the boiling temp. is a function of two variables, mol. mass and mol. vol., then  $T_b \sqrt{R} / \sqrt{M(1-R)} = \text{const.}$ , wherein  $M$  is the mol. wt. and  $R$  the sp. refraction corresponding to the mol. vol. In simple compds. such as the satd. hydrocarbons the sp. refraction can be calcd. from optical data. In polar compds. another empirical factor must be introduced. The equation retains its validity for the boiling temps. of satd. hydrocarbons at reduced pressures. Another equation can be derived from it by substitution which holds even at crit. temps.; it indicates the differences of vapor pressure of the individual constituents of a homologous series with satisfactory accuracy. EMIL KLARMANN

The "ebullioscopic paradox." A. BERTHOUD, E. BRINER AND A. SCHIDLOF. *J. chim. phys.* 26, 149-51 (1929); cf. *C. A.* 22, 11, 535.—The priority of Mazzucchelli (*C. A.* 22, 1712) in a similar treatment of this subject is acknowledged, but a polemical reply is made to the criticisms of Verschaffelt (*Wis. en nat. Tijds.* 4, 1 (1929)). T. H. CHILTON

A study of some complexes by the polarigraphic method. MME. N. DEMASSIEUX AND J. HEYROVSKY. *Bull. soc. chim.* 45, 30-5 (1929).—Study of complex formation by means of a modified dropping Hg cathode was extended to salts of Pt, Hg and Cu.  $\text{K}_2\text{PtCl}_6$ ,  $\text{K}_2\text{PtCl}_4$ ,  $\text{K}_2\text{PtBr}_6$  and  $\text{K}_2\text{PtBr}_4$  are completely dissocd. in soln.  $\text{K}_2\text{Pt}(\text{CN})_4$  is not dissocd. The metal cannot be deposited from the complex cyanides of Fe, Zn and Cu, but from Ag, Au and Cd complexes the metal can be deposited easily and reversibly at the cathode.  $\text{Hg}(\text{CN})_2$  behaves peculiarly in the presence of excess KCN. A sharp increase is observed on the polarization curve which is attributed to the adsorption of ions on the Hg drops. The cyano, oxalato, tartrato, and hyposulfito complexes of Cu were studied. The cyano complex is not dissocd. in a freshly prepd. soln. but is partly so in solns. which have stood for a time or which have been dild. L. L. Q

The connection between the osmotic coefficient and the chemical constitution of the ions of tetraalkylammonium salts. L. EBERT AND J. LANGE. *Z. physik. Chem., Abt. A, Haber Bd.*, 139, 584-96 (1928).—Debye and Hückel (cf. *C. A.* 17, 2665) have developed the following function for the osmotic coeff.  $1 - \phi = 0.37 v$  ( $v$  = mol. concn.). Several inorg. salts show discrepancies and the current theories to explain this are discussed. A series of salts of the  $\text{NR}_4$  base type are cryoscopically investigated in dilns. from 0.05 to 1 mol. per 1000 g.  $\text{H}_2\text{O}$ . They show a pronounced individuality. With the inorg. salts the halides were close together but with the org. salts the curves show great differences, which become more pronounced with the higher radicals. The salts  $\text{N}(\text{C}_2\text{H}_5)_4\text{I}$  and  $\text{N}(\text{C}_2\text{H}_5)_4\text{I}$  show the smallest lowering of the f. p. for salts with univalent cation and anion. They may give the best data to compare the different theories of the strong electrolytes. E. SCHOTTE

Equilibrium law of electrolytes. Association. K. JABLČEVŇSKI. *Roczniki Chem.* 9, 97-109 (109-10, French) (1929).—On the basis of the equil. law (*C. A.* 16, 3021) the cryoscopic data for the nitrates of alkali metals were recalcd. From the decrease of the coeff. with increasing concn. of nitrates it is concluded that the nitrates associate,  $\text{NO}_3^-$  combining with undissocd. mols., e. g.,  $\text{KNO}_3$  forming the complex anions  $(\text{KN}_3\text{O}_6)^-$ . Consequently the following equations were proposed:  $K_1 = (n_1 P)^{1/2} / (N - 2n_1)$  and

$K_2 = (n_1 P)^{1/2} / P^{1/2} (N - 2n_1)$ ,  $K_1$  being the equil. coeff. of concns.:  $n_1$  of alkali cation and  $n_2 (= P)$  of the anion  $\text{NO}_3^-$  and  $n_0$  of undissocd. mols.;  $K_2$  is the equil. coeff. of concns.:  $n_2$  of  $\text{NO}_3^-$  and  $n_0$  of undissocd. mols. and  $n_3$  of the complex anion  $(\text{MN}_3\text{O}_6)^-$ . The total no. of mols. is  $N$ . Calcn. gave the following results for  $\text{HNO}_3$ ,  $\text{LiNO}_3$ ,  $\text{NaNO}_3$ ,  $\text{KNO}_3$ ,  $\text{RbNO}_3$  and  $\text{CsNO}_3$ , resp.:  $K_1 = 3.36, 2.16, 2.16, 1.99, 2.11, 1.94$ ;  $K_2 = 0, 0, 1.1, 4.0, 4.0, 5.0$ ; hydration  $9\text{H}_2\text{O}, 11\text{H}_2\text{O}, 3\text{H}_2\text{O}, 0, 0, 0$ . The nitrates of Li, Na, K, Rb, Cs have almost identical equil. coeffs.; the coeff. for  $\text{HNO}_3$  is greater, as  $\text{HNO}_3$  behaves as an electrolyte far stronger than the salts. The same is true for  $\text{HCl}$  and its salts. There is no assocn. of mols. in the case of  $\text{HNO}_3$  and  $\text{LiNO}_3$ ; assocn. increases however, with increasing mol. wt. The tendency to assocn. depends upon the kind of cation. The degrees of hydration of cations of nitrates are identical with those of the chlorides.

JAROSLAV KUČERA

**The transport number of aqueous acetic acid.** JAMES W. MCBAIN AND CHARLES E. HARVEY. *Trans. Am. Electrochem. Soc.* 55 (preprint) 11 pp. (1929).—The migration number of a weak electrolyte has been ascertained and compared with the conflicting predictions from the data for corresponding strong electrolytes. The transport number of  $\text{HOAc}$  over the whole range of concns. and temps. studied is 0.108. It is shown that the anions of  $\text{HOAc}$  itself are simple and it is suggested that the anomalies in the data deduced for the strong electrolytes may be traceable to the presence of complex ions, even when they are in fairly dil. solns.

C. G. F.

**Transport numbers of lithium chloride, lithium bromide and sodium iodide in solutions of acetone and alcohol.** W. BIRKENSTOCK. *Z. physik. Chem., Abt. A*, 138, 432–46 (1928).—Transport nos. for Cl, Br and I ions in acetone solns. of  $\text{LiCl}$ ,  $\text{LiBr}$  and  $\text{NaI}$  are 1.21, 0.833 and 0.614, resp. Addn. of  $\text{MeOH}$  to the acetone soln. causes a sharp decrease in the transport no. of the anion of  $\text{LiCl}$  and  $\text{LiBr}$ , but there is no effect on the transport no. of I in  $\text{NaI}$ . The conclusion is that  $\text{LiCl}$  and  $\text{LiBr}$  form complexes in acetone that are destroyed by alc., while  $\text{NaI}$  forms no complexes in acetone.

R. J. HAVIGHURST

**The mobility of the hydrogen ion and the electrical conductivity of the halogen acids.** M. DE HLASKO. *J. chim. phys.* 26, 125–48 (1929).—New conductance measurements on the halogen acids gave values of  $\lambda_\infty$  at  $25^\circ$  for  $\text{HCl}$ ,  $\text{HBr}$ , and  $\text{HI}$ , 431.5, 433.7, 432.3, resp. From the mobilities of the anions, the value of 355.1 is obtained for that of  $\text{H}^+$ . From calcs. of the percentage ionized at various dilns., it is concluded that in very dil. solns.  $\text{HI}$  is stronger than  $\text{HBr}$ , and  $\text{HBr}$  than  $\text{HCl}$ . In concd. solns., the order is reversed. This is attributed to the effect of the acids on the dielec. const. of the soln. Measurements of the conductance of the poly-halogen acids and salts, taking account of the hydrolysis of the free halogen, indicate that  $\text{HI}$  is stronger than  $\text{HBr}$ , both being strong acids.

T. H. CHILTON

**Investigations on the Faraday effect in aqueous solutions of some uni-univalent electrolytes.** F. BUCH ANDERSEN AND R. W. ASMUSSEN. *Kgl. Danske Videnskab. Selskab Math.-fys. Medd.* 8, No. 9, 19 pp. (1928).—The magnetic rotations of several salt solns. were measured at  $0^\circ$  in a polarimeter of the Laurent type for the wave lengths  $578\mu$ ,  $546\mu$  and  $436\mu$ . The polarimeter tube (40 cm. in length with a capacity of 35 cc.) was surrounded by a solenoid of 7 ohms resistance through which a current of 20–23 amps. was flowing. All measurements were reduced to an arbitrary current of 19 amps. From the calibration of the app. with water it was calcd. that the magnetic potential was 80,000 gauss per cm. The total error is estd. to be not over 0.5%. Measurements were made on 24 different salts all of the uni-univalent type. The mol. rotation  $M$  was shown to vary slightly with the concn., and is not always the same for the three wave lengths. For yellow light  $M$  appears to increase with diln. for chlorides of small at. no. elements, but decreases for chlorides of large at. no. The rotation is very nearly additive in the halides of H, Li, Na, K, Rb and Cs, but the variation for a cation with different anions is large, while the variation for an anion with different cations is small. By assigning to  $\text{H}^+$  a value of  $M = 0$ , which is true if the H ion is identical with its positive nucleus, it is possible to calc. the values of  $M$  for the other ions. When these relative values are plotted against the at. no., the resulting curve approximates the ionic vol. and mol. refraction curves. The value of  $M$  decreases markedly in going from  $\text{MCl}$  to  $\text{MClO}_4$ , and from  $\text{MClO}_4$  to  $\text{Cl}$  in an org. mol. Similarly, it is increased by the substitution of Br for I. It is further observed that water has a rotation equal to about one-half of the sum of  $\text{H}^+$  and  $\text{OH}^-$  while ammonia has a rotation equal to the sum of  $\text{NH}_4^+$  and  $\text{OH}^-$ .

HANS C. DUUS

**The theory of electrolytic dissociation.** W. NERNST. *Z. physik. Chem.* 135, 287–50 (1928); cf. *C. A.* 22, 342, 1886.—The paper is a direct continuation of work by Nernst and Orthmann (cf. *C. A.* 23, 2645) and Meiring Naudé (*C. A.* 23, 2645).

Aq. solns. of electrolytes contain a considerable proportion of chemically bound mols. besides the free ions in agreement with the classical ideas of Arrhenius. The deviations from the law of mass action depend upon the electrostatic action of the ions, as has been assumed by previous investigators; the theoretical foundations have been provided through the work of Debye and collaborators. However, the theory of Debye does not lend itself readily to practical use because it contains factors about which little is known, e. g., the active ion radius and the dependence of the dielec. const. upon the distance of the ions. N. and collaborators restricted their work to univalent ions of equal mobility because in such case the Debye effect is small and the active ion radii are nearly equal. The following results were obtained and are particularly significant: It was possible to calc. the rather complex course of the heat of diln. with satisfactory accuracy from the heat of diln. of LiCl and from the temp. coeffs. of the heat of diln. of the other salts. The heats of assocn. and dissocn. were detd. The decrease of the numerical values of cryoscopic measurements caused by the Debye effect and by assocn. was detd. The degree of assocn. was detd. also from cond. measurements of salts with ions of equal mobility.

EMIL KLARMANN

**Electrochemical studies on ethereal solutions. II. The system: arsenic trichloride-ethyl ether.** M. USANOVICH. *Z. physik. Chem.*, Abt A, **140**, 429-34 (1929) cf. *C. A.* **21**, 1913.—The elec. cond. of the system:  $\text{AsCl}_3\text{-Et}_2\text{O}$  has been detd. in concns. ranging from 0 to 100%  $\text{AsCl}_3$ . A distinct conductance can be noticed at a concn. of 40%  $\text{AsCl}_3$ ; it rises with the rising concn. and the max. is reached at a concn. of 94%  $\text{AsCl}_3$ . At higher concns. the cond. falls rapidly. The temp. coeff. of the elec. cond. is negative at all concns. The decompn. potential of a soln. contg. 68.81% of  $\text{AsCl}_3$  was found to be 1.22 volts at 18°. The quantity of As deposited at the cathode in the course of electrolysis agrees with the requirements of Faraday's law. The curves of the sp. and the mol. conductivities correspond to those of the system  $\text{AsBr}_3\text{-Et}_2\text{O}$ .

EMIL KLARMANN

**The conductivity of solutions of some aliphatic organic acids in water and ethyl alcohol.** HERSCHEL HUNT AND H. T. BRISCOE. *J. Phys. Chem.* **33**, 190-9 (1929).—The conductivities of various fatty acids (acetic, propionic, butyric, isobutyric, valeric, isovaleric, caproic and isocaproic) and various halogen,  $\text{NH}_2$  and CN substitution products were measured for the dilns. 2, 8, 32, 128, 512, 1024. The aim of the investigation was to correlate the relative ease of H removal from the remainder of the acid mol. in both the  $\text{H}_2\text{O}$  and  $\text{EtOH}$  solns. Such factors as differences in dielec. const., viscosity, and assocn. will not explain the fact that conductivities of aq. solns. were 40-1000 times as great as those of alc. solns. Decided shifts in the abilities of the acids to conduct in the 2 solvents were noted. In general, homologous fatty acids stand in a series with decreasing mol. cond. as the no. of C atoms increase. The Lewis conception of the binding forces in the  $\text{COOH}$  group may be correct in so far as cond. data are a measure of the stability of the electronic bond between H and O.

H. R. MOORE

**Electrochemistry of the system: benzamide-bromine-nitrobenzene.** V. S. FINKELSTEIN AND O. K. KUDRA. *J. Russ. Phys.-Chem. Soc.* **60**, No. 5, 783-92 (1928).—Having previously (*C. A.* **20**, 3377) come to the conclusion that the  $\text{C}_6\text{H}_5\text{CONH}_2\text{Br}_2$  mol. is heteropolar, F. and K. proceeded to study the properties of the solns. of this electrolyte in  $\text{C}_6\text{H}_5\text{NO}_2$ . The electrolyte was prepd. by adding equiv. quantities of benzamide to solns. of Br in  $\text{C}_6\text{H}_5\text{NO}_2$ . The elec. conductivities were detd. by the method of Kohlrausch-Ostwald. The sp. conductivities at 25° and 35° are graphically presented in form of parallel curves; they continue to increase with the increase of  $\text{C}_6\text{H}_5\text{CONH}_2\text{Br}_2$  concns. up to 52%. A detailed study of the influence of temp. on elec. cond. could not be made, because on cooling the soly. drops sharply, whereas on heating the vapor tension of Br over the soln. is increased. At 25-35° benzamide has an insignificant soly. in  $\text{C}_6\text{H}_5\text{NO}_2$  and practically does not change its elec. cond. The curves of mol. elec. cond. have a typically anomalous character. The influence of an excess of Br is to increase the cond.: this result is explained according to Plotnikov's electrochem. resonance hypothesis (*C. A.* **21**, 1051) by the considerable ionizing power of Br toward the  $\text{C}_6\text{H}_5\text{CONH}_2\text{Br}_2$  mol. The compn. of the electrolyte was detd. by a method analogous to that of Chugaev and Koblyanskii (*C. A.* **7**, 3935) and it was established that  $\text{C}_6\text{H}_5\text{CONH}_2\text{Br}_2$  is the electrolyte of the system studied. By electrolysis Br was collected on the anode in accordance with Faraday's law, whereas crystals of benzamide were deposited on the cathode. The dependence of the current on the tension is proportional, which is explained by the polarizing action of the products of thermal dissocn. of electrolyte mols. The decompn. potential is absent, but this circumstance is not incompatible with this scheme of electrolytic dissocn.:  $\text{C}_6\text{H}_5\text{CONH}_2\text{Br}_2 \rightleftharpoons \text{C}_6\text{H}_5\text{CONH}_2^{++} + 2\text{Br}^{--}$ .

BERNARD NELSON

**Theory of changes in unpolarized electrodes.** M. VOLMER. *Z. physik. Chem.*, Abt. A, 139, Haber Bd., 597-604(1928). H. R. MOORE

**Recent investigations of the passivity of metals.** WOLF J. MÜLLER. *Z. Elektrochem.* 34, 571-86(1928).—A general account of the previously published work of M. and his co-workers. A consequence of M.'s theory is that the "passivating" power of an electrolyte may be expressed numerically. It is proposed to call "coating passivity" that kind of passivity which is characterized by the metal passing into soln. at stronger polarization with the valency of the active metal. B. C. A.

**Periodic passivity of chromium and chromium alloys, and the influence of temperature on passivity potentials.** B. STRAUSS AND J. HINNÜBER. *Z. Elektrochem.* 34, 407-15(1928).—An app. is described for the continuous registration of the potential at an electrode, and by means of it the potentials in dil.  $H_2SO_4$ , dil.  $HCl$ , and mixts. of both, of Cr-Fe alloys and Cr-Ni-Fe alloys of varying compn. which could be rendered passive, have been measured over several days. It is found that periodic phenomena occur, not only with Cr, but also with the alloys (cf. Adler, C. A. 7, 14). A necessary condition for the active-passive change is the presence of two phases which act as local elements. In one case the second element is Fe carbide, sepd. out from the austenite present, and in the other case it is Fe oxide. Theories of passivity are discussed, and it is pointed out that the assumption of an O film as the cause of passivity explains the fact that the change from active to passive metal and *vice versa* takes place continuously and without transition potential; if, on the other hand, the oxide skin theory is accepted, a definite transition potential should occur. A mechanism is suggested for the periodic phenomenon, based on the action of local elements and on the occurrence of a concn. polarization. Investigation of the influence of change of temp. on passivity potentials shows that, under certain conditions, the normal effect of fall of potential with rising temp. may be masked, and the potential may even rise. This phenomenon is explained from the point of view of the O-film theory. B. C. A.

**Electrode potential of nickel. II. Effect of occluded hydrogen on the electrode potential of nickel.** KWANJI MURATA. *Bull. Chem. Soc. Japan* 3, 253-61(1928); *Tech. Repts. Tôhoku Imp. Univ.* 8, 197-208(1929); cf. C. A. 22, 2102.—Cathodic polarization of the Ni electrode in dil. acid caused a slight decrease in the initial value of the e. m. f. Occluded  $H_2$  has no effect on the true electrode potential except in the presence of  $O_2$ ; hence it is concluded that for the measurement of the potential of the Ni electrode, complete exclusion of  $O_2$  is essential. MALCOLM DOLE

**Single potential of the copper electrode.** EDGAR NEWBERY. *J. Am. Chem. Soc.* 51, 1315-22(1929).—The variations in existing data on the single potential of a Cu electrode are traced to the formation of insol. films of basic  $Cu^{++}$  or  $Cu^+$  salts on the surface of the electrode due to a reaction between the electrolyte and Cu. The reaction is more rapid when air is present. By working quickly so that no film was formed the e. m. f. of the cell  $Cu|0.5 M CuSO_4|Hg_2SO_4|Hg$  was found:  $0.3630 \pm 0.0005$  v. at  $20^\circ$ , which is identical with the single potential of the two-phase Cu amalgam of Nielsen and Brown (C. A. 21, 3808). The abs. potential of the normal Cu electrode is 0.635 v. if that of the normal H electrode is 0.285 v. H. S. v. KLOOSTER

**Preliminary notes on an antimony electrode. I. The fundamental qualities.** F. VILS AND E. VELLINGER. *Arch. phys. biol.* 6, 38-54(1927).—The Sb electrode in contact with soln. of different  $p_H$  has been studied. In a liquid of definite  $p_H$  with one  $HgCl$  electrode, the Sb with an absolutely metallic surface has in the first moment a potential different from its definitive e. m. f. The curves of the e. m. f. represent two different types. They are steeper with a higher  $p_H$ . The final e. m. f. depends on the  $p_H$  and between  $p_H=1$  and  $p_H=12$  it is governed by a linear law,  $p_H = 0.0175 E + a$ . Differences exist between the different samples of electrodes, depending on the individual conditions and the temp. II. A practical differential adjustment. F. VILS. *Ibid* 92-6.—An arrangement of two electrolytic cells for  $p_H$  detn. is described, in which the difference of the e. m. f. is measured and the const. of the Sb electrodes eliminated. This method permits the rapid prepn. of buffers with gradually increased  $p_H$ . A. E. MEYER

**The velocity of saponification of esters and lactones by sodium hydroxide in mixtures of two and three solvents.** J. F. M. CAUDRI. *Univ. Leiden. Rec. trav. chim.* 48, 422-60(1929).—The object of this research was to investigate the influence of org. solvents on the velocity of the ring-opening of phthalide, investigated already in  $H_2O$  by Tasman (C. A. 22, 240, 584). Since this reaction resembles closely the sapon. of esters by alkali, the latter reaction was also investigated under the same circumstances. In general, the connection between velocity of reaction and compn. of the solvent is very irregular and not readily connected with any other phys. const. Very small quantities

of 1 solvent, added to another solvent, sometimes produce an enormous change in the velocity of reaction without any other phys. const. changing materially. In mixts. of alc. and water it is possible that a part of the NaOH is converted into NaOEt. According to Lobry de Bruyn and Steger (*Rec. trav. chim.* 18, 41, 311(1899)), most of the Na is present as alcoholate, even with alcs. very considerably dild. with water. If so, on the basis of Wegscheider's theory (*C. A.* 13, 2474) a good const. for a bimol. reaction may be expected, but the magnitude of that const. may depend on the initial concn. of the base used. This deduction is in accordance with published exptl data. A good bimol. const. cannot be expected in those cases in which the concn. of the water can no longer be considered const. during the reaction. It is shown, however, that the hypothesis of Lobry de Bruyn and Steger is not correct. When phthalide is hydrolyzed by NaOH in a mixt. of 5% alc. and 95% ether by wt., the Na salt of *o*-HOCH<sub>2</sub>C<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H is pptd.; only an insignificant amt. of the Na salt of *o*-EtOCH<sub>2</sub>C<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H can be formed. The velocity of the sapon. of phthalide was measured by the method of Tasman except that, after it had been shown that the re-formation of phthalide from HOCH<sub>2</sub>C<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H is a very slow reaction compared with the alkaline sapon., a measured quantity of the reaction liquid was brought into a small excess of dil. HCl. The const. for the sapon. of phthalide in H<sub>2</sub>O is  $K_{25}^{\circ} = 14.07$ ; for the reversed reaction it is 0.0156 in H<sub>2</sub>O, 0.0124 in 15% alc. and much less in 50% alc. For the sapon. of phthalide at 25° in mixts. contg. H<sub>2</sub>O and 10, 30, 50, 70, 90, 100 vol. % EtOH  $K$  is, resp., 12.53, 7.89, 4.27, 2.90, 1.55, 0; in mixts. contg. H<sub>2</sub>O and 15, 30, 50, 70, 90% MeOH,  $K$  is, resp., 8.97, 4.74, 1.78, 0.63, 0.095; in mixts. contg. H<sub>2</sub>O and 15, 30, 50, 70, 90% Me<sub>2</sub>CO  $K$  is, resp., 10.65, 7.96, 5.24, 4.83, 6.28. For the sapon. of EtOAc in mixts. of H<sub>2</sub>O and 0, 10, 30, 50, 70, 90, 100% EtOH  $K$  is, resp., 6.54, 6.23, 4.37, 2.17, 1.12, 0.34, 0; in mixts. contg. H<sub>2</sub>O and 15, 30, 50, 70, 90% Me<sub>2</sub>CO  $K$  is, resp., 5.83, 5.20, 3.86, 2.84, 3.29. For the sapon. of MeOAc in H<sub>2</sub>O and 0, 15, 30, 50, 70, 90% MeOH  $K$  is, resp., 10.56, 7.25, 4.28, 1.69, 0.51, 0.074. For the sapon. of phthalide and EtOAc in the system H<sub>2</sub>O-EtOH-Et<sub>2</sub>O:

Compn. of mixt. in Wt. %		Et <sub>2</sub> O	$K_{25}^{\circ}$	
H <sub>2</sub> O	EtOH		Phthalide	for EtOAc
62.2	24.8	13.0	4.30	2.48
40.2	29.8	30.0	3.43	1.70
32.4	54.6	13.0	3.07	1.14
26.1	43.9	30.0	3.29	1.13
20.5	34.5	45.0	4.13	1.28
9.8	60.2	30.0	2.12	0.43

The const. for the sapon. of EtOAc in H<sub>2</sub>O, when measured for the first time after prep. the soln., is 8.09 instead of 6.55 (*C. A.* 22, 240; cf. Cashmore, McCombie and Scarborough *C. A.* 16, 1527; Blakey, McCombie and Scarborough, *C. A.* 21, 1214). A 2nd proof that the Na salt rather than the ether of *o*-HOCH<sub>2</sub>C<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H is formed during sapon. of phthalide in strong alc. soln. is afforded by the fact that the velocity of re-formation of phthalide from its sapon. products is the same in H<sub>2</sub>O as in 80% alc. soln. The following conclusions were drawn: (a) The velocity of sapon. of phthalide is reduced by the addn. to the aq. solns. of EtOH, MeOH, Me<sub>2</sub>CO or Et<sub>2</sub>O and finally becomes zero in the abs. alcs. (b) The retarding action of MeOH exceeds that of EtOH. (c) With increasing amts. of Me<sub>2</sub>CO or Et<sub>2</sub>O the reaction const. do not decrease continuously, but increase again at fairly high concns. (d) If a mixt. of alc. and water contains little alc., the addn. of ether reduces the reaction const., whereas it is increased by the addn. of ether to a mixt., contg. more than 70% of alc. by vol. (e) Similar phenomena occur in the alk. sapon. of MeOAc and EtOAc under the same circumstances. An explanation of these phenomena is given in accordance with the hypothesis of Lapworth (*C. A.* 3, 738) and Rice (*C. A.* 22, 1270) that the activity of the ions becomes greater the smaller the hydration.

C. F. VAN DUIN

Application of reduced equations in chemical kinetics. WOJCIECH ŚWIENTOS-LAWSKI AND JAN G. ZAWIDZKI. *Roczniki Chem.* 9, 246-65 (265 French)(1929).—Zawidzki's conception of "reduced times" in kinetic equations are further developed and the equation  $\tau = f(x')/f(1/n) = {}^1f(x)$ , derived by introducing partial concns. (1 -  $x'$  and  $x'$ ) instead of mol. concns. ( $a - x$  and  $x$ ) and by replacing the time by the reduced time:  $\tau = t/h/n$ ,  $t/n$  being the time of transformation of the  $n$ th part of the initial substance and  $c$  a const. equal to  $1/f(1/n)$ . The values  $a$  and  $k$  (velocity const. of the reaction) disappeared in these equations. Consequently all reactions to which the formula  $dx/dt = K(a - x)^{-n}$  is applied can be represented on reduced coordinates by one curve for each value of  $n$  and  $p$ . A no. of equations were solved by calc.

the values  $x'$  and  $\tau$  relative to three different transformations of time, especially for  $1/n = 1/4, 1/2$ , and  $3/4$ . The curves were drawn expressing the course of different reactions by reduced coordinates ( $x'$  and  $\tau$ ).

J. KUČERA

**Kinetics of oxidations of organic compounds with bromine. II. Action of bromine on formic acid.** EDWARD JÓZSEFOWICZ. *Roczniki Chem.* 9, 309-24 (325 English) (1929); cf. *C. A.* 22, 4319.—The reaction between  $\text{Br}_2$  and  $\text{HCOOH}$  in dil. aq. solns. follows approx. the equation:  $dx/dt = K_1(a-x)^2/2x$ ,  $K_1$  decreasing during the reaction. The addn. of  $\text{HBr}$  diminishes the reaction velocity, the equation, in the presence of an excess of  $\text{HBr}$ , being:  $dx/dt = K_1(a-x)^2/(c+2x)$ . The addn. of strong acids, such as  $\text{HCl}$  and  $\text{HNO}_3$ , has a similar effect; the equation in this case is:  $dx/dt = K_1(a-x)^2/(0.75c+2x)$ . Addn. of bromides decreases only a little the reaction velocity, addn. of chlorides and nitrates slightly, whereas the addn. of  $\text{Na}_2\text{SO}_4$  is followed by a considerable increase in the reaction velocity. No perceptible influence of light on the course of reaction was found. The temp. coeff. between  $20^\circ$  and  $30^\circ$  is 2.26. The mechanism of the reaction is explained by assuming a direct action between formic ions and bromine mols.  $\text{HBr}$  formed diminishes the reaction velocity: (a)  $\text{H}$  ions diminish the dissocn. of formic acid, and (b)  $\text{Br}$  ions form with  $\text{Br}$  mols. tribromide ions, which do not act on formic acid.

J. KUČERA

**The cryoscopic determination of the molecular equilibrium of resorcinol in aqueous solutions of potassium chloride.** F. BOURION AND CH. TUTTLE. *Compt. rend.* 188, 1110-1 (1929); cf. *C. A.* 22, 3337.—The mol. equil. of resorcinol in 0.5 and 1.225  $M$  solns. of  $\text{KCl}$  has been detd. cryoscopically. In the two series the equil. between simple and double mols. extends up to concns. 0.5  $M$  in resorcinol. Between simple and triple mols. it extends from 1.00 to 1.750 and 1.875  $M$ . The cryoscopic consts. were 18.4 for water, 22.3 for 0.5  $M$  and 25.0 for 1.225  $M$   $\text{KCl}$ . This difference in consts. is explained by an adsorption of the water by the ions and mols. of the salt. A. C. H.

**Equilibrium in the liquid state between potassium and sodium and their bromides.** E. RINCK. *Compt. rend.* 188, 1108-9 (1929).—R. has previously studied the equil. of the hydroxides and of the chlorides (Hackspill and R., *C. A.* 21, 3527). The equil. of the bromides in the molten state was studied by heating in iron tubes at  $800^\circ$ , cooling suddenly and analyzing the two phases present. The equil. const.  $C = [\text{Na}][\text{KBr}]/[\text{K}][\text{NaBr}] = 28.8$  with a max. deviation of 20%.

A. C. HIGGINS

**The displacement velocity of silver in silver telluride, antimonide and stannide.** G. V. HEVESY AND W. SEITH. *Z. anorg. allgem. Chem.* 180, 150-8 (1929).—The displacement velocity of silver in  $\text{Ag}_2\text{Te}$ ,  $\text{Ag}_3\text{Sb}$  and  $\text{Ag}_3\text{Sn}$  was studied by following the diffusion velocities of these substances in the corresponding  $\text{Cu}$  compds. The diffusion velocity of  $\text{Ag}_2\text{Te}$  in  $\text{Cu}_2\text{Te}$  may be expressed by the formula  $D = Ac - B/T$ , where  $A = 2.027 \times 10^4$  and  $B = 10,430$ . The displacement velocities of these three substances, calcd. for the same fraction of the abs. m. p. ( $0.76 T_m$ ), decreases by approx.  $10^{-2}$  in the following order:  $\text{Ag}_2\text{Te} > \text{Ag}_3\text{Sb} > \text{Ag}_3\text{Sn}$ . High displacement velocities are noted for those compds. intermediate between the salt-like type and the intermetallic ones. In the case of the strongly heteropolar salt-like compds. and the metal itself the displacement velocity in the lattice is extremely small.

**Topochemistry of contact catalysis. II. An experimental case of adlineation.** G. M. SCHWAB AND E. PIETSCH. *Z. physik. Chem., Abt. B*, 2, 262-3 (1929).—By the radioactive indicator method of Paneth, it is shown that the exchange adsorption of heavy metals on crystal gratings in many cases, particularly in many naturally grown crystals as crocoite, does not occur upon the whole crystal surface, but takes place principally along the edges of the crystal. Photographs obtained by imposition of crocoite crystal surfaces with adsorbed radioactive lead upon a photographic plate show the very strong adlineation of the adsorbate along the crystal edges. It must be imagined that the less rigid bond of the edge particles leads just as it does to exchange adlineation also to an adlineation of molecules foreign to the gratings.

B. HAMILTON

**Catalytic action of organic compounds containing iron.** HANS V. EULER, HARALD NILSSON AND DAGMAR RUNEHJELM. *Svensk Kem. Tid.* 41, 85-92 (1929). (In German).—The catalytic activities of hemin (I), mesohemin (II), deuterohemin (III) and pyratin (IV) are compared. An activity unit is defined as reaction const./millimol.  $\text{Fe}$ . The reaction mixt. contains 0.0082 mol.  $\text{H}_2\text{O}_2$  buffered with borate to  $p_H$  8.5. The temp. is  $0^\circ$  and aliquots are titrated with  $\text{KMnO}_4$  at 10-min. intervals. The following equiv. units were obtained: I 0.6, II 1.7, III 1.0 and IV 0.8. It was also run with phosphate buffer  $p_H$  6.7 giving 1.1. A series of expts. was carried out in which the oxidation of phenolphthalein reduced with  $\text{Zn}$  dust was used as catalase index, and the

end colors were compared in a colorimeter. If the value for I is 100, the others become: II 125, III 200 and IV 1000. A. R. ROSE

**Kinetics of the solution of aluminum and of cadmium in hydrochloric acid.** K. JABLŲCZYŃSKI, E. HERMANOWICZ AND W. WAJCHSŁEWSKI. *Z. anorg. allgem. Chem.* 180, 184-92(1929).—The process of soln. of Al and of Cd in HCl was studied by measuring the amt. of  $H_2$  evolved and calcg. the speed of reaction. The results indicate that the soln. of Al in HCl is a purely chemical reaction, unaffected by diffusion. The high temp. coeff. ( $K = 2.36$ ) indicates increase in activity of the metal with rise in temp. The speed of soln. was found directly proportional to the concn. of HCl (where the concn. varied from 0.2 N to 0.8 N). Passivated Al dissolved very slowly. The rate of soln. did not increase with time; this led to the conclusion that the passive oxide layer is deep-seated. Passive Al has a high temp. coeff. ( $K = 2.47$ ), indicating that the passive condition disappears with rise in temp. The data indicate that the soln. reaction is monomol. in nature. Activation of Al with  $HgCl_2$  caused the diffusion reaction to become paramount. The rate of soln. of Cd in HCl decreased rapidly with time. Activation caused more pronounced action, which increased with time. Stirring did not affect the rate of soln., which leads to the conclusion that the soln. of Cd in HCl is also purely chem. L. F. AUDRIETH

**The ternary system: water-sodium nitrate-potassium nitrate.** EUGÈNE CORNEC AND HENRI KROMBACH. *Caliche* 10, 5-15(1928); *Compt. rend.* 188, 788-90(1929).—Previous measurements of this ternary system have been confined to ordinary temp. The soly. of  $NaNO_3$  increases by addn. of  $KNO_3$  and that of  $KNO_3$  diminishes slightly and then increases greatly by addn. of  $NaNO_3$ ; at  $100^\circ$  these changes become more pronounced. The % compn is given as  $H_2O$  15.2,  $NaNO_3$  36.7,  $KNO_3$  4.81. The mutual increase in soly. of  $KNO_3$  and  $NaNO_3$  is due to the formation of a double salt in soln. The isotherm at  $111.7^\circ$  was detd.; it has 2 branches relating to 2 pure nitrates. H. R. MOORE

**The ternary system: water-sodium sulfate-sodium nitrate.** ANDRÉ CHRÉTIEN. *Compt. rend.* 188, 1047-50(1929).—The five solid phases present between  $0^\circ$  and  $100^\circ$  are ice,  $NaNO_3$ ,  $Na_2SO_4 \cdot 10H_2O$ ,  $Na_2SO_4$  and  $Na_2SO_4 \cdot NaNO_3 \cdot H_2O$ , darapskite. This last has a narrow incongruent field over the temp. range  $13^\circ$  to  $74^\circ$ . Isotherms were obtained, but are not given in the paper. F. R. BICHOWSKY

**The system: sodium iodate-sodium chloride-water.** H. W. FOOTE AND JOHN E. VANCE. *Am. J. Sci.* [5], 17, 425-30(1929).—The ternary system was studied from the lowest eutectic to  $35^\circ$ . Soly. isotherms were detd. at  $0^\circ$ ,  $15^\circ$ ,  $25^\circ$  and  $35^\circ$  by the method of wet residues and the relations plotted in a solid model. The results indicate that 6 different solid phases can exist in contact with various solns., one of them being a double salt never before described, of compn.  $2NaIO_3 \cdot 3NaCl \cdot 10H_2O$ , stable between  $-21.2^\circ$  and  $+24.6^\circ$ . Two ternary eutectics (1)  $0.36\% NaIO_3$ ,  $23.28\% NaCl$  at  $-21.18^\circ$ , (2)  $0.34\% NaIO_3$ ,  $19.93\% NaCl$  at  $-16.9^\circ$ , were established in addn. to 3 invariant transition points. At (1) ice, double salt,  $NaCl \cdot 2H_2O$ , soln. and vapor are in equil. while at (2) ice, double salt,  $NaIO_3 \cdot 5H_2O$ , soln. and vapor occur. The other solid phases in the system are  $NaCl$  above  $0.04^\circ$  and  $NaIO_3 \cdot H_2O$  above  $6.8^\circ$ . R. H. F.

**Contributions to the ceramics of highly refractory materials. II. The system: zirconia-lime.** OTTO RUFF, FRITZ EBERT AND EDWARD STEPHAN. *Tech. Hochschule, Breslau. Z. anorg. allgem. Chem.* 180, 215-24(1929).—Study of the m.-p. diagram of the system:  $ZrO_2$ -CaO reveals two eutectics, contg. resp., 30 and 60 mol. %  $ZrO_2$ , and the compd.  $CaZrO_3$ . X-ray Debye-Scherrer photographs verify the existence of this compd. and also show that CaO and  $ZrO_2$  form mixed crystals with a CaO content varying from 0 to 40 mol. %. Evaluation of the Debye diagrams gives to the compd. a monoclinic structure, closely bordering on the cubical,  $\beta \sim 89^\circ$ . The density calcd. from these data is  $d_c = 4.74 \pm 0.05$ , which agrees very well with the value obtained pycnometrically,  $d_p = 4.78 \pm 0.05$ . Chem. analyses not only verify the existence of  $CaZrO_3$ , but prove that no vaporization of CaO takes place on fusion. The differences between the systems:  $ZrO_2$ -CaO and  $ZrO_2$ -MgO are readily explained by consideration of the size relationships which obtain among the ionic radii of the three cations involved ( $Ca^{++} = 1.06$ ,  $Zr^{IV} = 0.93$ ,  $Mg^{++} = 0.78$  A. U.). L. F. AUDRIETH

**The thermal decomposition of ozone at low pressures.** LOUIS S. KASSEL. *Z. physik. Chem., Abt. B*, 2, 264-5(1929).—The decompn. of complicated mols. proceeds under high pressures according to the second order, under low pressures according to the first order, and under still lower pressures again according to the second order with increasingly large velocity consts. This second transition is known for several reactions (decompn. of azomethane, propionaldehyde, etc.), and it has been indicated that the decompn. of acetaldehyde probably is an example of the first transition. Ozone

shows this behavior. There is no other triatomic gas known which decomposes monomolecularly; and no other monomolecular reaction shows such a low velocity as is found for ozone. If the primary process in the monomolecular reaction is  $O_3 = O_2 + O$ , with a reaction heat of 20,000 calories, and if the heat of formation of ozone is 35,000 calories, then from this it follows that the heat of dissoen. of the oxygen is about 110,000 calories. The value according to the work detd. from the spectrum is about 150,000 calories.

B. HAMILTON

**van der Waals' equation and thermodynamics.** J. E. VERSCHAFFELT. *Compt. rend.* **188**, 312-3(1929); cf. *C. A.* **22**, 1716.—Exception is taken to the statement of Vasilescu-Karpen (*C. A.* **23**, 1792) that van der Waals' equation can be derived thermodynamically without recourse to Carnot's principle. The internal energy must be included; necessarily involves the second law, since change in entropy is considered as an exact differential.

RAYMOND H. LAMBERT

**The principle stated by Carnot; the theorem. Formulas of the second law of thermodynamics independent of any source.** C. RAVEAU. *Compt. rend.* **188**, 313-6 (1929).—The equation for the 2nd law of thermodynamics is incapable of interpretation from the principle stated by Carnot, since the cycle employed is actually the result of two simple cycles impossible to separate. This idea therefore needs profound revision. By use of the idea of fixed irreversibility consequences can be deduced in which no definition need be employed. The mathematics is given for completing such a cycle whereby a triangular area is utilized in place of the customary parallelogram. The method for obtaining the sign for the various terms in the 2nd law is discussed.

### 3—SUBATOMIC PHENOMENA AND RADIOCHEMISTRY

S. C. LIND

**Determination of parameters in crystal structure by means of Fourier series.** W. LAWRENCE BRAGG. *Proc. Roy. Soc. (London)* A123, 537-59 (1929).—The representation of the scattering matter in a crystal by Fourier series first used by W. H. Bragg and later developed by Duane, Havighurst, and Compton is applied here to the detn. of the parameters in a complex crystal. A series is used which gives the projection of the scattering matter in the unit cell on each of its faces in turn. Conclusion: The method may be used in conjunction with an analysis of the usual type of crystal by assigning parameters to atoms and may considerably shorten the labor. The series is particularly of value in discovering the positions of the lighter atoms and in leading directly to precise values of the parameters. The use of the method is shown in connection with measurements recently published by West and B. and it is shown that it is in satisfactory agreement.

**Structure of the methane molecule.** G. W. BRINDLEY. *Nature* 123, 760-1 (1929).—If the C-H bond consists of a shared L electron from C and the H electron, there would be a difference in type for the 2<sub>1</sub> and the 2<sub>2</sub> electrons. This is confirmed by mass spectrograph evidence of Hogness and Kvalnes (cf. *C. A.* 23, 2650).

**The constitution of oxygen.** HAROLD D. BABCOCK. *Nature* 123, 761 (1929).—New spectrograms at low solar altitudes confirm the existence of the isotope O<sup>18</sup> and the relative band intensity indicates a ratio of 1/1300.

**Properties of the terms of the helium molecule.** G. H. DIEKE. *Nature* 123, 716-7 (1929).—From a study of band spectra it is found that the influence of the inter-nuclear axis on the valence electron predominates over that of the nuclear rotation in most moles.

**Reflection of hydrogen atoms from crystals.** Intensity measurements of the specularly reflected beam. THOS. H. JOHNSON. *J. Franklin Inst.* 207, 629-37 (1929); cf. *C. A.* 22, 4362.—Quant. measurements were made of the intensity of the specularly reflected beam of H atoms from a crystal of rock salt, as a function of the angle of incidence and of the temp. of the crystal. The ratio of the intensity at an angle near grazing

becomes greater as the temp. of the crystal is reduced, and the intensity of the specular beam at any particular angle is greater at low temps. than at high temps. I. J. P.

**Reflection of hydrogen atoms from crystals. Velocity selection in the specular beam.** THOS. H. JOHNSON. *J. Franklin Inst.* 207, 639-43(1929); cf. *C. A.* 22, 4362, and preceding abstr.—In order to discover whether velocity selection takes place in a specularly reflected beam of H atoms, the beam was reflected from a second rock salt crystal. If the first specularly reflected beam contains only atoms with certain selected velocities, it should be reflected from the second crystal with greater intensity than a beam contg. the same no. of atoms distributed according to the Maxwellian law. There is little, if any, velocity selection. I. J. PATTON

**Quantum mechanical theory of the anomalously large effective cross sections of atom systems during energy transfer.** H. KALLMANN AND F. LONDON. *Naturwissenschaften* 17, 226-7(1929).—The excitation energy is often transmitted from one atom to another at distances far exceeding those derived from the kinetic gas theory, *e. g.*, in resonance fluorescence. In particular this effect becomes noticeable when a min. amt. of translation energy is involved in the transfer. The theory of quantum mechanics gives a satisfactory explanation of this anomaly (cf. following abstr.). For the cross section of a special energy transfer 2 factors are important: (1) the sharpness of resonance  $\sigma$  measured as  $\sigma = h(\nu_M - \nu_M'')$  with  $\nu$  the values of the transition frequencies of the 2 atoms, (2) the energy of interaction  $W_{12}$ , *i. e.*, a Coulomb type of interaction of the charge distribution of the active parts of the atoms for the transitions in question. Factor  $W_{12}$  can be expressed for "permitted" transitions as a function of the dipole

moments of the virtual oscillators involved:  $W_{12} = \frac{\mu_1 \mu_2}{R^3}$ . From the theory follows an ap-

parent cross section of the atom for the energy transfer of  $q = \pi \int_0^\infty \frac{R dR}{1 + \left(\frac{\sigma}{2W_{12}}\right)^2}$  and in

the permitted transitions  $q = \left(\frac{2\mu_1 \mu_2}{\sigma}\right)^{2/3} \cdot \frac{\pi^2}{3\sqrt{3}}$ . In a graph is shown for  $\mu_1 = \mu_2 =$

$1.2 \times 10^{18}$  how  $q$  depends on  $\sigma$ . Corrections applied to the equation are that for  $\sigma > /a$  temp. effect enters based on the max. kinetic energy available at the temp., also that for sharp resonance ( $\sigma$  close to zero) the energy transfer at the very large distances of the 2 atoms becomes slow and so limits the practical sphere of action. Allowance

being made for the last effect, it is found that  $\lim_{\sigma \rightarrow 0} q = \pi^2 \frac{\mu_1 \mu_2}{h\nu}$  with  $\bar{\nu}$  the mean rela-

tive velocity of the 2 atom species; this correction is also dependent on temp.; for higher velocities the transfer becomes less efficient at sharp resonance. For the NaD line virtual oscillators with  $\mu = 1 \times 10^{-17} \bar{\nu} = 3 \times 10^4$ , the  $q$  value is about 100,000 times the normal one from kinetic theory. For non-permitted transitions  $q$  values of tenfold normal in second-order collisions may occur;  $W_{12}$  is then a function of the higher multipoles.

B. J. C. VAN DER HOEVEN

**Quantum mechanical energy transfers between atomic systems.** H. KALLMANN AND F. LONDON. *Z. physik. Chem., Abt. B*, 2, 207-43(1929); cf. preceding abstr.—A quantum mech. analysis of energy exchange between atoms in different quantum states. The probability is calcd. for the interchange of energy between an excited and an unexcited system in terms of the potential energy of interaction and the defect from resonance between the 2 systems. This probability, in the general case, is periodic in the time. Curves are drawn for the probability of exchange for various adiabatic and non-adiabatic approaches and sepn. of the systems. An adiabatic approach and sepn. lead to no interchange; but it is shown that gas kinetic motions at ordinary temp. cannot be regarded as adiabatic. In a statistical assembly, the equation for the no. of approaches leading to transfer is shown to be of the same form as that for the no. of gas kinetic collisions, in which the gas kinetic effective cross section is replaced by an apparent cross section  $\sigma$ , which is a function of the resonance defect and the energy of interaction. The apparent cross section grows very rapidly as  $\sigma$  diminishes, being, for instance, for a resonance defect of 20 millivolts about 50 times the gas kinetic value and increasing to larger values for closer resonance. The probability of transfer is influenced by the temp. in 2 ways: the mol. motions must not be too slow, or approaches and sepn. will be adiabatic and hence there will be no excitation; they must not be too vigorous, since the transfer itself requires a finite time. The abnormally large values of effective cross section will therefore hold only for a limited temp. range. These general conclusions are applied in detail to the special cases of collisions of the

2nd kind between A and H<sub>2</sub>, Hg and Na, to the  $2^1P_1 \rightarrow 2^1P_0$  transition in Hg, to the depolarization of fluorescent light, to energy exchanges in chem. reactions, and to the broadening of spectral lines by the addn. of foreign gases. W. WEST

**Quantum mechanics of many-electron systems.** P. A. M. DIRAC. *Proc. Roy. Soc. (London)* A123, 714-83(1929).—The Bohr atom model, according to which the stationary states correspond to electron orbits, is now replaced by a structure in accordance with quantum mechanics in which the orbits are replaced by quantum-mech. states represented by a wave function in 3 dimensions. According to the old theory the spins were either parallel or anti-parallel, necessitating large forces coupling the spin vectors, an assumption not justified by theory. The new theory shows that there is a definite magnitude of the spin vector connected with each stationary state, but in general it is not possible to give a meaning to the direction of spin. An explanation of multiplet structure requires some means of accounting for the large coupling energy between spin vectors. The soln. is provided by the exchange interaction of the electrons, which arises because of the electrons being indistinguishable from one another. A proof is given for the existence of exclusive sets of states and a formula is derived for the energy levels of these states. C. J. HUMPHREYS

**Study of phenomena of groupings of the atoms of radioelements.** C. CHAMIE. *J. phys. radium* [6], 10, 44-8(1929); cf. C. A. 22, 910.—Examn. of solns. of radioactive elements indicates that the atoms of these elements are distributed through the mixt. as clusters or groups forming a sort of colloidal soln. The method of study is to bring the radioactive mixt. into intimate contact with a photographic plate. After development the presence of the groups is indicated by spots on the plate having the appearance of stars. The plate is subsequently examd. by aid of a microscope. The usual procedure is to mix the active substance with Hg, but other liquids yield similar results. For the examn. of Rn the gas is blown against the plate. While each radioactive substance yields a characteristic pattern, this phenomenon of grouping seems to be common to all families of radioactive elements. C. J. HUMPHREYS

**The cosmic radiations and their relation to physical and cosmic processes.** LISE MEITNER. *Z. angew. Chem.* 42, 345-51(1929).—M. presents a summary of the investigations on the so-called cosmic radiation, giving the results and theories of Hess, Hoffmann, Kohlhorster, Millikan, Steinke and others. She discusses their penetration, intensity, measurement (describing in detail Hoffmann's app. with a diagram), relation to radioactive radiations, wave length, daily variations in intensity, and theories of their origin, such as Nernst's idea of radioactive decompn. of trans-uranium elements, or atomic synthesis in interstellar space. WILLIAM E. VAUGHAN

**Cosmic radiation and radioactivity.** LOUIS R. MAXWELL. *J. Franklin Inst.* 207, 619-28(1929).—M. investigated the effect of cosmic rays on the disintegration of Po, by measuring the activity at the bottom of an 1150-ft. mine. He found no observable change. From theoretical considerations he concludes that there should be no appreciable effect even at the earth's surface. I. J. PATTON

**Cosmic radiation and radioactive disintegration.** N. DOBRONRAVOV, P. LUKIRSKII AND V. PAVLOV. *Nature* 123, 760(1929).—Filtering out of cosmic rays by 20 ft. of sea water caused no change in the radioactivity of Rn above the exptl. error, 1%. This radiation might, however, be sufficient to start disintegration of U, since the disintegration const. is small. GREGG M. EVANS

**Microcalorimetric determination of the absorption of  $\gamma$ -radiation from radium C.** FELICITAS WEISS-TESSBACH. *Sitzb. Akad. Wiss. Wien., Abt. IIa*, 137, 551-62(1928).—W.-T. gives a brief summary of the dissertation of J. Tischler (unpublished) on the heat of absorption by Pb of various thicknesses (0.28-1.7 mm.) of the  $\alpha$ , and some of the  $\beta$  and  $\delta$  radiations from Ra and Po preps. W.-T. used screens of Pb, Cu and Al 5-13 mm. thick. The results are considerably lower than those obtained by Yovanovitch (C. A. 18, 3001; 20, 2784). The ratio of the heating effects of the 3  $\delta$  components is 1:6.8:10.8. I. J. PATTON

**Structure of atomic nuclei.** ERNEST RUTHERFORD. *Proc. Roy. Soc. (London)* A123, 373-90(1929).—The accomplishments since the introduction of the nuclear atom model are briefly reviewed, including the work of Aston establishing the isotopic constitution of ordinary elements, the proof of the artificial disintegration of certain elements by  $\alpha$ -particles accompanied by the liberation of protons, and the detn. of the frequencies of  $\gamma$ -rays by Ellis. Conclusions from  $\alpha$ -ray scattering expts. are presented. It is pointed out that for nuclei of at. nos. 29 to 92  $\alpha$ -particles are scattered according to the inverse-square law, but that scattering is abnormal for lighter elements, indicating attraction for close approach. The general conclusion is that the nucleus must have a certain vol. or structure. It is evident that the nucleus is surrounded by a very high

potential barrier. The escape of  $\alpha$ -particles through this barrier is explained by new mechanics. The effect of packing in the nucleus as related to the atom as a store of energy is discussed by aid of Aston's curves. The formation of atoms up to at. wt. 120 is accompanied by emission of energy. For heavier atoms the  $\alpha$ -particles or protons which make up the external nuclear structure are less closely bound, resulting in a larger energy content as we proceed to higher at. nos.

C. J. HUMPHREYS

**Question of yield in atomic disintegration experiments.** GERHARD KIRSCH AND HANS PETTERSSON. *Sitzb. Akad. Wiss. Wien., Abt. IIa*, 137, 563-82(1928); cf. *C. A.* 23, 561.—The results of K. and P. and of Bothe and Fränz (*C. A.* 21, 2601, 3152; 22, 1902) are discussed, with the conclusion that Bothe and Fränz's method is untrustworthy.

I. J. PATTON

**Design and use of a double camera for photographing artificial disintegrations.** P. M. S. BLACKETT. *Proc. Roy Soc. (London)* A123, 613-29(1929).—The necessity of photographing a very large no. of  $\alpha$ -ray tracks in order to observe artificial disintegrations, because of the exceedingly small probability of collision between an  $\alpha$ -particle and a nucleus, demands that the photographic app. be constructed so as to provide for the photographing of as large a no. of tracks as possible at one time. In the arrangement described, the camera plates are set at right angles but the lenses are tilted so that the plane of the chamber is conjugate with the planes of both lenses. The necessary trigonometric calcns. for the detn. of the angles in space between colliding particles are given. The interrelation of the depth of focus, the intensity of images, and the magnification is discussed. It is desirable to reduce the last as far as the resolving power of the emulsion will permit. A reduction of pressure or the dila. of the gas with  $H_2$  or He increases the yield of resolved collisions as well as the range of the disintegration product, so that the details of the collision process may be observed more easily.

C. J. HUMPHREYS

**The wave theory of electrons.** G. P. THOMSON. *Chemistry & Industry* 48, 311-5 (1929); cf. *C. A.* 22, 4353.—A qual. discussion of the expts. of T. showing diffraction with 20,000-60,000-v. electrons and of Davisson and Germer with electrons of a few hundred v. velocity. It is shown that the application of the wave theory to chem. facts is more successful than the orbit theory.

H. R. MOORE

**Elastic collisions of electrons with helium.** N. F. MORR. *Nature* 123, 717(1929).—The scattering of 210-v. electrons by He has been calcd. by wave mechanics. It is plotted and compared with the curve from the classical theory. They differ widely for small angles, and only the quantum curve agrees to any extent with the exptl. results of Dymond and Watson (cf. *C. A.* 22, 1273).

GREGG M. EVANS

**Electronic analysis. Diffraction of electrons by the oxides of magnesium, zinc and cadmium—the law of Louis de Broglie.** M. PONTE. *Compt. rend.* 188, 909-10 (1929).—Diffraction methods, hitherto developed, are applied to ZnO, MgO and CdO, with electrons of 16,670 or 10,870 v. velocity. Lattice dimensions are estd. to a 1% accuracy.

H. R. MOORE

**A study of the mobility of ions in gas mixtures whose components are electro-negative.** HERBERT MAYER. *Bul. stiinte fizice soc. romând stiinte* 29, 35-94(1926-7).—The mobilities of positive and negative ions were detd. for an atm. of pure, dry  $O_2$  and for a mixt. of  $O_2$  and  $Cl_2$ , the concn. of  $Cl_2$  being varied from 50 to 4.5%. An approx. calcn. was made of the relation of mobilities found for positive and negative ions in pure  $Cl_2$  at 80 mm. pressure. The method used was that of the Rutherford alternating field as modified by Franck and Pohl. Instead of a sinusoidal, a static alternating field was used, produced by a high-tension battery and revolving commutator. For  $O_2$  the mobilities found were  $k_{pos-760} = 1.38$  cm./sec. per volt/cm.,  $k_{neg-600} = 2.05$  cm./sec. per volt/cm. Introduction of  $Cl_2$  in such small amts. as 0.5% reduces considerably the mobility of negative ions, but does not affect that of positive ions appreciably. After reaching the concn. at which mobility of positive ions equals that of the negative ions, the mobility of the positive ions is also affected perceptibly, but remains constantly greater than that of the negative ions. The relation of the 2 mobilities in pure  $Cl_2$  at 80 mm. pressure (Hg) is  $k_{pos.}/k_{neg.} = 1.222$ . Comparison of results obtained with previous theories of mobility of ions shows that these results cannot be explained by the theory of complex ions. It also shows that there are elec. forces which play an important part in formation of mol. groupings which do not permit characterization by the dielec. const. To explain the difference in mobilities of positive and negative ions it is necessary to make use of forces depending upon electronegative or electro-positive nature of the gas, which Franck has called electronic affinity. E. M. S.

**The influence of chlorine on mobility of ions in hydrogen.** HERBERT MAYER. *Bul. stiinte fizice soc. romând stiinte* 29, 108-15(1926-7); cf. *C. A.* 22, 19.—The mobility

of positive and negative ions in pure, dry  $H_2$  was detd. by the alternating field of the Rutherford-Franck-Pohl method, finding  $k_{pos.760} = 6.00$  cm./sec. per volt/cm. and  $k_{neg.760} = 10.07$  cm./sec. per volt/cm. Then increasing amts. of  $Cl_2$  were introduced, beginning with 0.3%, and the mobilities of the 2 kinds of ions detd. for each concn. The mobility of the positive ion is altered considerably by the presence of  $Cl_2$ , while that of the negative ion diminishes, even for traces of  $Cl_2$ , below that of the positive ion. These results confirm the Cluster theory of ionic complexes and indicate also the existence of elec. forces between ions and neutral mols. These forces are not due only to dielec. polarization of the latter because of the ions, but more to the elec. structure of atoms of different gases.

E. M. SYMMES

The theory of electron scattering in gases. ALLAN C. G. MITCHELL. *J. Franklin Inst.* 207, 753-64; *Proc. Nat. Acad. Sci.* 15, 520-5(1929).—Mathematical. E. H.

The recombination of gaseous ions. LEONARD B. LOEB. *Trans. Am. Electrochem. Soc.* 55 (preprint) 15 pp.(1929).—Because of insufficient modern exptl. data available, it has been impossible to formulate the theory of the recombination of gaseous ions accurately. The recent results of Marshall, who used a direct method of study of great flexibility, has made it possible to answer the questions outstanding. It is shown experimentally by Marshall, as well as theoretically by Sommerfeld and L., that the recombination process for gaseous ions is primarily a process of random drifting together of ions, the attractive forces playing a role only in the last free path or two between the ions. On account of the non-random distribution of the ions in ionization (ions generated in pairs close together) the value of  $a$  undergoes an apparently rapid decrease in the first 0.1 sec., and the value of  $\alpha$  in short time intervals depends on the duration of the flash, the period of recombination and the initial concn. of ions. The true value of the coeff. for air probably lies in the neighborhood of  $0.9 \times 10^{-8}$ , instead of  $1.6 \times 10^{-8}$ , as usually assumed. Free electrons play no direct role in the recombination of ions, as studied in gases near atm. pressure. The electrons can recombine with positive ions only by first attaching to mols. to form negative ions. The independence of  $a$  of the mobilities of ions is a direct consequence of the Thomson theory of a recombination due to thermal agitation, and depending largely on temp. and the unknown masses of the ions in most gases.

C. G. F.

A comparative study of certain properties of electrons and the ions of the alkali metals. C. H. KUNSMAN. *J. Chem. Education* 6, 623-33(1929).—A non-technical article. K. describes an app. contg. a new source of  $K^+$  ions as compared to the equiv. electron source and presents a summary of phys. and chem. expts. in which similar results are sought with electrons and positive ions under the same conditions, such as (1) the activation of  $N_2$  and  $H_2$  in the synthesis of  $NH_3$ , (2) detn. of the work function  $\phi$  for positive ions, (3) bombardment of metal surfaces and (4) excitation and ionization.

WILLIAM E. VAUGHAN

Diffraction of electrons by metal films. E. RUPP. *Ann. Physik* [5], 1, 773-800 (1929); cf. *C. A.* 22, 3094; 23, 563.—When electrons pass through thin films of metals of cubic lattice structure, diffractions are observed. These were electrically measured by (a) a ring collector in which the beam velocity is so adjusted that the known diffraction ring just fits the opening of the collector ring, and (b) by a movable Faraday cylinder by which the angle between the cylinder and the incident beam can be varied. The position of the diffraction ring is found to coincide with that previously calcd.. From the index of refraction,  $\mu$ , the lattice potential  $E$ , for  $Ag \sim 12$  v. and that for  $Ni \sim 17$  v. Diffraction electrons are defined (from expts.) as those which are diffracted on passage through a metal film within a small angle without appreciable loss in velocity; others are merely scattered electrons. G. P. Thomson's theory (*C. A.* 23, 1049) of the refraction does not hold for the films, as these are random conglomerates of small crystals.

LOUIS WALDBAUER

The mechanism of spark discharge in air at atmospheric pressure. LEONARD B. LOEB. *Science* 69, 509-12(1929).—If, in consequence of fortuitous arrangement of electrons, the negative cloud of one should approach the positive cloud of the one ahead of it, a large local increase of potential gradient might be produced. The distances of less than one mm. necessary to accomplish this would account for the unexpectedly small time lag found in recent expts. by others.

GREGG M. EVANS

Electron reflection and diffraction at single crystal surfaces. E. RUPP. *Ann. Physik* [5], 1, 801-13(1929); cf. *C. A.* 23, 2649.—By a modified Davission and Germer (*C. A.* 22, 4354; 23, 29) exptl. arrangement, the reflections of electrons from metallic single crystal surfaces were detd. for  $Ni$ ,  $Cu$ ,  $Ag$ ,  $Au$ ,  $Al$  and  $Pb$ . The diffraction maxima were found to correspond with those calcd. by the de Broglie equation (*C. A.* 22, 3094) if the index of refraction,  $\mu$ , is introduced to explain the systematic deviations.

These indices are due to the inner lattice potentials,  $E_0$ , of the metals.  $E_0$  is related to the work function  $A$ , by means of the Sommerfeld theory of metallic conduction.

LOUIS WALDBAUM

**Diffraction of cathode rays by powdered crystals.** TOSHINOSUKE MUTO AND TASABURO YAMAGUTI. *Proc. Imp. Acad. (Tokyo)* 5, 122-4 (1929).—The values of spacings obtained by means of cathode rays with powder. MgO and graphite are in good accord with those from x-rays. A fair agreement is also found in the relative intensities of the rings.

C. J. WEST

**Measurement of excitation and ionization potentials by the diffusion method.** W. GLIWITZKY. *Ann. Physik* [5], 1, 701-20(1929); cf. Bartels, *C. A.* 22, 1538.—The crit. potentials of A were measured by the Hertz differential method and by the diffusion method proposed by Bartels. The latter method was also employed with mixts. of He and Ne. Excitation potentials of A were found at 11.51, 12.89, 14.02 and 14.79 v., with a well-defined ionization potential at 15.81 v. All the crit. potentials are complex, and correspond to the excitation of a term group; e. g., the first one corresponds to a 4-term excitation at 11.49, 11.57, 11.67 and 11.78 v. The detd. max. depends on the probabilities within the term group, and possibly on the relationships within the app. (electron velocity distribution, etc.). The He-Ne measurements were only carried out at 0.3 mm., and Ne gave excitation potentials at 16.6 and 18.5 v., agreeing with Hertz's and spectroscopic data. Helium gave a measured ionization potential at 24.5 v. The new method does away with the need for a calibrating gas, and, as opposed to Hertz's method, gives a well-defined max. for the ionization potential.

L. W.

**The ionization of potassium vapor.** R. W. DITCHBURN AND F. L. ARNOT. *Proc. Roy. Soc. (London)* A123, 516-36(1929).—App. is described similar to that used by Smyth. Ions are produced by: (1) photo-ionization, (2) electron impact, (3) emission of  $K^+$  ions by a Kunsman filament with subsequent attachment to neutral atoms to form  $K_2^+$ . By the first method the only ions formed are  $K^+$ . The evidence indicates that the  $K^+$  ions are formed by the ionization and dissocn. of  $K_2$  mols. The electron impact method yields  $K^+$  and  $K^-$  ions and evidence of the existence of unstable  $K_2^+$ ,  $K_1^+$  and  $K_3^{++}$ . It is shown that the lives of the unstable compds. are of the order of  $10^{-6}$  secs. The number of  $K_2^+$  ions formed according to the third method, including those which dissoc., is about 10% of the no. of incident  $K^+$  ions. Because of the conservation of linear momentum, half the energy of the impacting particle, in the formation of the  $K_2^+$  ion, must be radiated or transformed. It probably appears as continuous radiation. In general, high temp. and low voltage are favorable to the dissocn. of  $K_2^+$  ions. It is believed that  $K_2^+$  ions exist in two states, one of which can be dissocd. and the other, which is an excited state, cannot until after a return to the first; this presumably is caused by an increase in temp., giving rise to collisions of the second kind. It is assumed that all the transitions of the  $K_2$  mols. and  $K_2^+$  mol. ions are such that the moment of inertia increases and the heat of dissocn. decreases on excitation.

C. J. HUMPHREYS

**The passage of electric current through a Cooper-Hewitt mercury lamp.** SARVENDRA RAY. *Z. Elektrochem.* 35, 89-93(1929).—The author offers an explanation for the rectifying action of Cooper-Hewitt Hg lamp, which only lights up when Hg is cathode and anode is vapor. The light is a result of a process set up when the arc starts. The theory of "inner elec. discharge of atom" is expanded to cover the Hg lamp. The substance called "Z" is loosened by inner discharge of Hg atoms and is absorbed either on each mol. or on groups, of Hg mols. Passage of d. c. through gas in the Cooper-Hewitt lamp is a case of electrolysis of the hypothetical substance "HgZ." The cycle of reactions of Hg and "Z" is outlined on the basis of this theory.

M. McMAHON

**The adsorption of hydrogen on the surface of an electrodeless discharge tube.** M. C. JOHNSON. *Proc. Roy. Soc. (London)* A123, 603-13(1929).— $H_2$  was dissocd. by introducing from outside a ring discharge (cf. *C. A.* 22, 725, 2709). Micromanometer readings were taken every 15 secs. Curves of adsorption fatigue are given for two bulbs. The adsorbed layer of at. H is never more than one mol. thick. The heat of adsorption of at. H was found to be 11,000 cal. A micromanometer is described, sensitive to  $10^{-6}$  cm., with a range of 0.05 cm.

GERALD M. PETTY

**The photoelectric effect of ultra-violet rays on gases.** R. DANTINNE AND P. LENAERTS. *Arch. sci. phys. nat.* [5], 11, 5-14(1929).—A special app. is described, consisting essentially of a condenser type of ionization chamber. A p. d. of 1000 v. is put on one of the plates and a quadrant electrometer is connected to the other. The photo-ionization of  $O_2$ ,  $CO_2$  and  $SO_2$  is studied at atm. pressure. It is shown that a relation exists between the relative intensities of the effect on different gases and the

relative intensities of the effect of the same radiation on a metallic surface held in the same gas. The Hertz effect, or photoelec. effect on metals, is considered from this work to have its origin in the ionization of adsorbed gas. H. R. MOORE

**Photo-ionization of cesium vapor.** F. L. MOHLER, C. BOECKNER, R. STAIR AND W. W. COBLENTZ. *Science* 69, 479(1929).—The photo-ionization of Cs vapor was redetd. by means of an ionization chamber designed to reduce the surface photo-elec. effect to a min. The Hg 3130 line gives 78% of the photo-ionization, and there is no effect on the red side of this line, showing the absence of surface effect. The mean atomic absorption coeff.,  $k_{3130} = 1.85 \times 10^{-19}$  for the Cs pressure range of 0.005—0.06 mm. (corresponding to a temp. range 146–201°).  $k_{3134} = (2.3 \pm 0.2) \times 10^{-19}$ . The error lies in the uncertainty in the temp. measurement of the Cs, and does not take into account the uncertainties in the v.-p. data of Cs. Little's value of  $k_{3130} = 2.2 \times 10^{-21}$  is unexplained, as his exptl. values were of the same order of magnitude (C. A. 21, 3155). LOUIS WALDBAUER

**A new integrating photometer for x-ray crystal reflections, etc.** W. T. ASTBURY. *Proc. Roy. Soc. (London)* A123, 575–602(1929).—The theory and construction details are given of an integrating microphotometer in which the photographic negative is replaced by a carbon print and light by  $\alpha$ -rays. The integrating action is obtained because the total ionization is made a measure of the total x-ray intensity, whatever the distribution over the photographic image. It is possible to attain direct proportionality between the x-ray intensities and the  $\alpha$ -ray ionizations observed in the electroscop. The essential features of the app. are an effectively uniform deposit of Po placed near a thin strip of mica, in which a slit is cut to allow the  $\alpha$ -rays to pass through to the carbon tissue and thence to the electroscop. The extension of the use of the photometer to  $\alpha$ -,  $\beta$ - and  $\gamma$ -rays, and also to visible light is discussed. It can be applied to the measurement of the integrated intensity of any radiation, the photographic density of which is exponential or approx. so. C. J. HUMPHREYS

**Study, by x-rays, of the superficial or interfacial orientations by the tangent-drop method.** JEAN J. TRILLAT. *J. phys. radium* [6], 10, 32–43(1929).—A new method is described for the study of mol. orientations at a surface of sepn. liquid-liquid, liquid-solid, solid-gas, or liquid-gas, by aid of diffraction patterns produced by x-rays. Essentially the method is to direct a beam of x-rays by aid of a collimating tube so that it just grazes a drop of the substance to be examd. This drop is either liquid or solidified from the molten state. The diffracted rays impinge on a photographic plate. The method is applied to a study of the action of the fatty acids on Hg and yields the result that the lattice spacing of the Hg salt is proportional to the no. of C atoms on the compd. It is also applied to a study of the superficial structure of long-chain C compds. in the form of solid drops, and to the mol. structure of oleate of Pb at various temps. C. J. HUMPHREYS

**The emission of soft x-rays by different elements at higher voltages.** O. W. RICHARDSON AND F. S. ROBERTSON. *Proc. Roy. Soc. (London)* A124, 188–96(1929); cf. C. A. 21, 3551.—Since previous work using voltages up to 500 has shown that efficiency of emission of soft x-rays increases to a max. at the middle of the periodic system and then falls off, the authors have applied voltages up to 6000 in order to see if the emission becomes more like that of ordinary x-rays, whose efficiency is proportional to the at. no. over the whole range of the periodic table. Their preliminary results indicate no striking change between voltages of 500 and 6000. MALCOLM DOLE

**Intensity of total scattering of x-rays.** I. WALLER AND D. R. HARTREE. *Proc. Roy. Soc. (London)* A124, 119–42(1929).—An approx. formula is deduced for the total scattering of x-rays by atoms of a monatomic gas. This formula is applied to the special case of scattering by He atoms, taking the wave functions which correspond to the case of vanishing interaction. The formation of approx. wave functions of required symmetry properties for an atom contg. several electrons is discussed, and these wave functions are applied to obtain the scattering formula in a more explicit form. The relation between scattering by a many-electron atom and by a one-electron atom is considered. W. and H.'s formula for total scattering is evaluated for A and compared with the exptl. data. The theoretical values agree with the expt. if the exptl. values are multiplied by the factor 1.25 to convert them to abs. values. MALCOLM DOLE

**The ultra-violet optical properties of  $\alpha$ - and  $\beta$ -naphthalenesulfonic acids.** DENISE LITTOLEFF. *Arch. phys. bol.* 6, 97–128(1927).—The Ca salts of both acids show 5 bands at  $\lambda$ 321, 307, 275, 252 and 230. The two spectra are very similar to each other and to that of naphthalene. The absorption is slightly higher in the  $\alpha$  deriv. than in the  $\beta$ . In both it is higher at  $p_H$  2.75 than at  $p_H$  9.1. The fluorescence is stronger in the  $\beta$  than in the  $\alpha$  salt. The mol refraction of the Ca and Na salts in the

visible and ultra-violet light shows a very slight inflection (negative) for the  $\alpha$  and very slightly more for the  $\beta$  compd.

A. E. MEYER

**The spectra of As III and Sb III.** P. PATTABHIRAMIAH AND A. S. RAO. *Indian J. Physics* 3, 437-44(1929).—Classifications of the lines emitted by doubly ionized As and Sb are presented. The terms which have been found to account for the lines belong to the doublet system and arise when the outer  $p$  electron is shifted to the various outer orbits. If an  $s$  electron is shifted both doublet and quartet terms arise, but in the present analysis no quartet terms have been established.

C. C. KRESS

**The spectrum of doubly ionized chlorine.** K. MAJUMDAR AND S. C. DEB. *Indian J. Physics* 3, 445-50(1929).—This paper presents an extension of the analysis of Cl III made by Bowen (*C. A.* 22, 1100). The new terms, which have been found are  $^4P$ ,  $^4D$ , and  $^4F$ , and their combinations with known terms account for the identification of 30 addnl. lines. The details of the investigation are given in the tables.

C. C. KRESS

**The spectrum of hydrogen.** The bands analogous to the parhelium line spectrum. III. IV. O. W. RICHARDSON AND P. M. DAVIDSON. *Proc. Roy. Soc. (London)* A124, 50-68, 69-88(1929); cf. *C. A.* 23, 3163.—The details of the analysis of the  $H_2$  band systems are presented which represent transitions from the initial electronic levels  $^1K$ ,  $^1L$ ,  $^1M$ ,  $^1N$ ,  $^1O$ , and  $^1Q$  to the final electronic level  $2^1S$ . These bands are all built up of  $P$  and  $R$  branches of approx. equal strength, in marked contrast with those described previously. In each progression the lines alternate in intensity. In addn., a description is given of 2 progressions, starting at 4142.8 A. U. and 4097.4 A. U., which consist apparently of only  $Q$  branches; and of 4 progressions lying in the deep red and near infra-red consisting of  $P$  and  $R$  branches.

C. C. KRESS

**Intensity relations in the spectra of titanium.** II. Relative intensities of the stronger multiplets of Ti I. GEO. R. HARRISON AND HARRY ENGWICHT. *J. Optical Soc. Am.* 18, 287-301(1929).—The method of photographic photometry described in an earlier paper (*C. A.* 23, 1570) was applied to the measurement of the intensities of lines in 16 multiplets of Ti I emitted in the vacuum arc. The multiplets selected for measurement form triads and result from transitions between the middle energy states and the low metastable and ground states of the atom. The results confirm Kronig's formulas for multiplet intensities in triads especially if the temp. of excitation of the arc is taken at 10,000° abs. In a triad resulting from a 2-electron jump the intensities agree qualitatively with Kronig's formulas for the nearest equiv. 1-electron jump. The strongest line in the spectrum under normal excitation conditions is 3653.49 A. U., which confirms its character as *raie ultime*, established by spectrochem. methods.

C. C. KRESS

**Zeeman effect in the spectrum of ionized neon (Ne II).** C. J. BAKKER. *Proc. Acad. Sci. Amsterdam* 32, 515-22(1929).—See *C. A.* 23, 1567.

E. C. M.

**Study of the absorption of a screen of blue rock salt.** PIERRE LEROUX. *Compt. rend.* 188, 904-7(1929).—Light-absorption measurements have been made of the blue Stassfurt salt as a function of wave length and temp. Absorption coeffs. are recorded for the Hg lines  $\lambda 3655-5460$  at 18° and 220°. At the higher temps. a rapid decrease in absorption is noted; i. e., the min. of absorption is displaced to longer wave lengths. A slab 0.107 cm. in thickness loses coloration on heating to 250°.

H. R. MOORE

**Broadening and displacement of spectral rays by molecular diffusion.** JEAN CABANNES AND PIERRE SALVAIRE. *Compt. rend.* 188, 907-8(1929).—With the aid of a Perot and Fabry echelon, it was found that the 4358 A. U. radiation of Hg is broadened asymmetrically by mol. diffusion in butane at atm. pressure. A total increase of 0.04 A. U. was noted, of which 0.01 A. U. was toward the red. The effect is due to fluctuations in the orientation of anisotropic mols., but radiation giving fluctuations in d. (resulting in the displacement toward the red) is also noted. The displacements are found to be 0.065 A. U. for MeOH, 0.05 for EtOH, 0.070 for PrOH, 0.055 for  $CH_3COOH$ , and 0.035 A. U. for benzene.

H. R. MOORE

**Hartmann equation for the calibration of spectral apparatus.** FR. HOFFMANN. *Physik. Z.* 30, 238-9(1929).—H. shows by calcn. that the formula given by Russell and Shenstone (*J. Optical Soc. Am.* 16, 298(1928)) for the calibration of prism spectroscopes in terms of the frequency instead of the wave length is in greater error than Hartmann's original formula.

LOUIS WALDBAUER

**An amplifier for comparison spectra.** PIÑA DE RUBIES. *Anales soc. españ. fis. quim. (tecnica)* 28, 48-56(1929).—A device allowing direct comparison of different spectrograms obtained on different plates, is described. Simultaneously with direct observation this device allows detg. the spectrogram of a mineral and of the main elements contained in it. In addn. to the speed with which any spectrogram can be

interpreted there is also a proof on which the degree of accuracy of analysis can be carried to the desired degree.

**Spectra of boron.** W. D. LANSING AND W. F. TYLER. *Trans. Illinois Acad. Sci.* 21, 210-11(1928).—Crude B prep'd. by Moissan's method is placed in a combustion tube, dried at red heat in a current of  $H_2$ , and then treated with  $Cl_2$ . The  $BCl_3$  is condensed and then purified by distn. The pure  $BCl_3$  is mixed with pure  $H_2$  and passed over a hot W wire; B is formed on the wire. The pure B thus prep'd. consists of beautiful, hard, gray crystals. The method of photographing the arc and spark spectra is given. The regions 2050 A. U. to 5200 A. U. and 4500 to 6680 A. U. are being studied.

**The absorption spectrum of lithium hydride and its molecular constants.** G. NAKAMURA. *Z. physik. Chem., Abt. B*, 3, 80-2(1929).—A partial analysis of the many-line spectrum of LiH has been made from absorption data. The band system is composed of a number of partial bands degraded toward the red, each of which consists of a simple P and R branch. The moment of inertia in the normal state has been calcd. to be  $2.90 \times 10^{-40}$  g. cm.<sup>2</sup> and the equil. distance between nuclei is  $1.42 \times 10^{-8}$  cm.

**Densitometric measurements of the  $K\alpha$  line of carbon.** C. B. BAZZONI, FAUST, AND WEATHERBY. *Nature* 123, 717(1929).—Densitometric measurements of the  $K\alpha$  line of C in 3 orders obtained with a grating having 1200 lines per cm. show distinct sepn. of components in the second and third orders. There are 4 principal components in the main line at 44.2, 42.0, 45.4 and 46.15 A. U. The relative intensities apparently depend on excitation potential, thus explaining the divergence of wave length obtained by other observers in the third order.

**Polarization of radiations for the resonance of zinc.** PAUL SOLEILLET. *Compt. rend.* 187, 723-5(1928).—By reason of resonance of metallic vapors, radiations of excited rays are emitted that are polarized and are extremely sensitive to a weak magnetic field. Previous results for Hg and Cd have been followed up for Zn. From values of the magnetic field in the direction of excited rays and in the direction of observed rays the av. life of an excited atom is calcd. to be  $10^{-8}$ . This is much greater than for the other two metals. Stability depends both on the simplicity of the electronic structure and on the no. of atoms present. This radiation for Zn at  $\lambda = 3076$  is compared with that at  $\lambda = 2139$ . The latter, however, is difficult to measure because of the weak sensitivity of plates in this region.

**The optical activity of quartz perpendicular to the optical axis.** G. SZIVESSY AND C. SCHWEERS. *Ann. Physik* [5], 1, 891-947(1929).—The authors' expts. have shown that results of W. von Voigt (*Göttinger Nachr.* 1903, 171) and F. Wever (*Jahrbuch der phil. Fakultät d. Univers. Göttingen* 1920 [2], p. 206) on the optical activity of  $\alpha$ -quartz perpendicular to the optical axis are incorrect and that previous experimenters were deceived by defective parallelity of light. Measurements carried out by authors' methods show that "the component of gyration tensors perpendicular to optical axis in  $\alpha$ -quartz is disappearingly small; the gyration surface is therefore a very flat tened rotation ellipsoid with disappearingly small equator diameter."

**Raman effect in crystals.** HISAMITU NISI. *Proc. Imp. Acad. (Tokyo)* 5, 127-9(1929).—Raman spectra are given for quartz, topaz and calcite. No trace of Raman lines was found in fluorspar.

**Raman effect in atomic hydrogen.** BORIS PODOLSKY. *Nature* 123, 761(1929).—The Raman effect can be calcd. from P.'s former solution of the Schrödinger equation (cf. C. A. 22, 2312, 4048).

**The modifications of the spectra of organic compounds dependent on the pH and the mathematical formulation of the functions relating the conditions of absorption to the pH.** F. VLÉS AND M. GEX. *Arch. phys. biol.* 6, 69-91(1927).—A general equation, formulated previously, is applied to some org. substances and the calcd. const. are compared with those empirically found.

**Polarized fluorescence.** ELSBETH HAKENBECK. *Ann. Physik* [5], 1, 457-96(1929).—A detailed study is made of the fluorescence properties of uranin (sodium fluorescein) in glycerol. The following facts are established: (1) The degree of polarization is a function of the direction of vibration of the incident light; (2) observations of the degree of polarization as a function of the soln. medium give the mol. radius with the aid of Perrin's formula; (3) measurements of the refractive indices give the order of magnitude of the const. of quasi-elastic binding.

**The influence of boric acid on the phosphorescence of zinc sulfides prepared by the explosion method.** F. PREYER. *Compt. rend.* 188, 903-4(1929).—The advantage of the "explosive" mode of prep. ZnS from the elements consists of incorporating in

the mixt., before explosion, the substances whose effect on the phosphorescence it is desired to evaluate. A series of ZnS mixts. with increasing amts. of  $\text{H}_2\text{BO}_3$  gave an increase in the intensity of luminosity within the range 5–20%  $\text{H}_2\text{BO}_3$ . An optimum amt. of  $\text{H}_2\text{BO}_3$  was assocd. with greatest luminescence.

H. R. MOORE

**Optical relations between alkali halide phosphors and complex salt solutions.** HANS FROMHERZ AND WILHELM MENSCHICK. *Z. physik. Chem.*, Abt. B, 3, 1–40(1929); cf. C. A. 23, 3180.—F. and M. have attempted to show that the optical activity produced in cryst. alkali halide phosphors by a trace of heavy-metal salts is identical with the activity produced in solns. of such halides by the addn. of heavy-metal salts and that it is due to complex formation. With this in view they have obtained the extinction curves for solns. of NaCl, NaBr, KCl, KBr, KI,  $\text{NaClO}_4$ ,  $\text{AgClO}_4$ ,  $\text{Cu}(\text{ClO}_4)_2$ ,  $\text{CuCl}_2$ ,  $\text{CuBr}$ ,  $\text{NaCl} + \text{AgCl}$ ,  $\text{KCl} + \text{AgCl}$ ,  $\text{NaBr} + \text{AgBr}$ ,  $\text{KBr} + \text{AgBr}$ ,  $\text{KI} + \text{AgI}$ ,  $\text{AgClO}_4 + \text{AgI}$ ,  $\text{KCl} + \text{CuCl}_2$ ,  $\text{KBr} + \text{CuBr}_2$ ,  $\text{KCl} + \text{CuCl}$ ,  $\text{KBr} + \text{CuBr}$ , and have compared them with existing data on the absorption bands of cryst. phosphors. The absorption bands of pure alkali halide solns. are displaced about  $30\text{m}\mu$  toward the red as compared with the crystal bands. The absorption bands of complex alkali halide solns. with Ag and Cu salts agree in relative position, form and sharpness with the corresponding crystal bands but are displaced 6 to  $10\text{m}\mu$  toward the red. From a comparison of the intensities of the bands it is estd. that from 0.2 to 2% of the heavy-metal salt in the crystal lattice is sufficient to produce optical activity.

J. B. AUSTIN

**The statistics of the photon.** IOAN I. PLACINTEANU. *Ann. sci. univ. Jassy* 15, 359–62(1929).—According to the statistical methods of Gibbs the probability ( $p$ ) of a photon forming an excited mol. of the order  $r$  is  $p = e^{[(\psi/\theta) - r\{\alpha + (\epsilon/\theta)\}]}$  where  $\epsilon$  is the energy,  $\theta = KT$  (Boltzmann const. times abs. temp.) and  $\psi$  and  $\alpha$  are consts. If  $r = 0$ , that is, if there is no excitation, the equation reduces to the classical form; if  $r = 0.1$  the equation reduces to the Fermi-Dirac form; if  $r = 0, 1, 2r$ , it reduces to the Bose-Einstein form.

F. R. B.

**A test of the radiation hypothesis of chemical reaction.** WM. URE AND RICHARD C. TOLMAN. *J. Am. Chem. Soc.* 51, 974–83(1929).—The rate of racemization of liquid piene exposed to infra-red radiation at about  $156^\circ$  was measured optically. The rate was not accelerated by a large increase in the density of radiation over the range of wave lengths out to  $3\mu$ . No conclusion as to the effectiveness of wave lengths longer than  $3\mu$  was warranted.

R. L. DODGE

**Active nitrogen.** P. K. KICHLU AND S. BASU. *Nature* 123, 715–6(1929).—Increase of life of active N from the electrodeless discharge with decrease in pressure is taken as evidence that this form of active N consists of metastable mols. Spectral results from uncondensed discharges show that no appreciable density of atoms exists.

**Active nitrogen.** LORD RAYLEIGH. *Nature* 123, 716(1929); cf. preceding abstract.—R. calls attention to an earlier article (cf. *Proc. Roy. Soc. (London)* A86, 264) describing the giving-off of light by active N under compression; and expresses doubt of the correctness of the conclusions of K. and B.

GREGG M. EVANS

**A new case of photochemical catalysis. The reaction between nitric oxide and cyanogen and its mechanism.** R. G. W. NORRISH AND F. P. P. SMITH. *Trans. Faraday Soc.* 24, 620–9(1928).—If the system cyanogen-NO is exposed to light of wave length shorter than  $360\text{m}\mu$  when under a partial pressure of  $1/2$  to  $1/3$  atm. for each reactant the reaction  $4\text{NO} = \text{N}_2 + 2\text{NO}_2$  occurs; cyanogen is thus a photochem. catalyst. The increase in “Draper” effect and of the fall in pressure with time was followed for a no. of partial pressures of reactants. The photochem. reaction is similar to that of  $\text{H}_2$  and  $\text{Cl}_2$ . Fall in pressure occurred also in the dark.  $\text{O}_2$  as an impurity appears necessary for the reaction. The curves assume the same shape if produced back to  $\text{O}_2$  content. Wave length of active light lies in the region  $360$ – $220\text{m}\mu$ .  $\text{N}_2\text{O}$ ,  $\text{N}_2$  and  $\text{CO}_2$  accumulate as the reaction proceeds. Equations are presented for the mechanism of the reaction in which NOCN is an intermediate product. This in turn is attacked by  $\text{NO}_2$  in presence of light forming  $\text{NO}$ ,  $\text{N}_2$  and  $\text{CO}_2$ . Fall in pressure is due to polymerization of  $\text{NO}_2$ . An analogous mechanism has been observed in the system NO–CNCl, an account of which is to be given later.

RAYMOND H. LAMBERT

**Studies in photochemistry. II. The Shear test applied to maize oil.** A. J. PACINI AND R. W. CROSLBY. *Clin. Med.* 36, 34–8(1929); cf. C. A. 22, 3546.—Maize oil gave a positive Shear test after exposure to the action of infra-red radiation and also after ultra-violet radiation.

M. H. SOULE

**The influence of pressure on the photochemical formation of hydrogen bromide.** I. W. JOST AND G. JUNG. *Z. physik. Chem.*, Abt. B, 3, 83–94(1929).—Previous work is discussed at length and several references are given. Theoretical considerations show

that the reaction velocity is proportional to  $\sqrt{1/p}$  and that the recombination of an excited with a normal Br atom takes place in only a very small fraction of all collisions. The effect of pressure was investigated with a specially constructed app. and the above conclusion verified within the limits of accuracy of the procedure. II. W. JOSR. *Ibid.* 95-127.—The effect of pressure on the photochem. formation of HBr, the influence of the container walls and the effect of light from the band spectra and from the continuous spectrum of the Br<sub>2</sub> was investigated with an improved app. for studying the effect of pressure on velocity of "light" reactions. The reaction velocities in the band region and in the continuum are practically equal. The Br atoms recombine in triple collisions and may also be destroyed on the walls, so that the walls have a characteristic effect on the reaction velocity. The activated Br atoms formed in the primary action affect the reaction velocity like the unactivated because they are deactivated before they can react. The velocity consts. of the single reactions occurring in the formation of HBr have been recalcd. and found in agreement with the theory. C. W. W.

**Phosphorescence and photochemical action of some organic and inorganic compounds after exposure to ultra-violet light.** F. KIRCHHOFF. *Physik. Z.* 30, 240-1 (1929).—After exposure to ultra-violet light from a quartz-Hg lamp, the following showed phosphorescence: fluorene, phenyl- $\beta$ -naphthol, benzoin, the ash of a photochemically active paper, boric acid and Ca(H<sub>2</sub>PO<sub>3</sub>)<sub>2</sub>. The Zn salt of an org. sulfonic acid and BaPt(CN)<sub>4</sub> were not phosphorescent. Of the compds. treated with ultra-violet light, fluorene and the Zn salt of the sulfonic acid showed an appreciable effect on a photographic plate and BaPt(CN)<sub>4</sub> a very great effect, while the others showed none or scarcely any. Two phenomena seem to occur, viz., phosphorescence followed by a brief photochem. effect (in fluorene), and an invisible radiation (perhaps ultra-violet) of relatively long photochem. duration (in BaPt(CN)<sub>4</sub>). LOUIS WALDBAUER

**Effect of x-radiation on crystalline and dissolved sucrose.** M. C. REINHARD AND K. L. TUCKER. *Radiology* 12, 151-3(1929); cf. C. A. 23, 2996.—X-rays color crystals of sucrose reddish brown. These crystals, when dissolved, show measurable amts. of invert sugar. In solns. some invert sugar is formed, the amt. being proportional not to the concn., but to the time of exposure, for a given quality of radiation

E. H. QUIMBY

**Effect of cathode rays on hydrocarbon oils and on paper. The mechanism of cable deterioration.** C. S. SCHOEPFLE AND L. H. CONNELL. *Ind. Eng. Chem.* 21, 529-36(1929).—The wax found in cable is formed by condensation of the impregnating compd. due to the action of the silent discharge and is accompanied by the liberation of H<sub>2</sub>. Paper under the influence of the silent elec. discharge produces appreciable amts. of H<sub>2</sub>O as well as gases, H<sub>2</sub>, CO<sub>2</sub>, etc. The gases and H<sub>2</sub>O formed within the cable during use are very important factors causing deterioration. Numerous tables and curves are given, showing the results of a large number of expts. Improvement in the cable can probably be expected if the silent discharge can be eliminated by changes in design, or if an impregnation compd. and a paper or suitable substitute can be found which will not produce gases and H<sub>2</sub>O when subjected to the silent discharge.

O. A. NELSON

**A vacuum arc lamp of new design for spectroscopic work (PROSAD) 4.** Ultra-violet light-transmitting glasses (STARKIE, TURNER) 19. Influence of Fe<sub>2</sub>O<sub>3</sub> content on the light transmission of soda-lime-SiO<sub>2</sub> glass, with special reference to the ultra-violet (STARKIE, TURNER) 19. Absorption spectra of some phthaleins of the trihydroxyphenols (GIBBS, SHAPIRO) 10. Absorption spectra of some halogenated fluorosceins (GIBBS, SHAPIRO) 10. Tautomerism of hydroxytriarylcarbinols (ANDERSON) 10. Structure and activation of aliphatic aldehyde molecules. II. Formaldehyde, acetaldehyde, propionaldehyde and chloral. III. Absorption spectra of solutions (SCHOU) 10.

COLIN G. FINK

**High-frequency induction furnaces.** G. RIBAUD. *Tech. moderne* 21, 225-31, 265-71 (1929).—Recent progress in the manuf. and uses of these furnaces is described.

P. THOMASSET

**Electrically heated rotary carburizer.** H. M. CHATTO. *Iron Age* 123, 1153-4 (1929).—An elec. rotary carburizing furnace is described, the installation consisting of a rotating alloy cylinder inside an electrically-heated, box-shaped furnace chamber. The feature is 2 point control, which gives uniform temp. in the cylinder, a rapid uniform penetration of C and which economizes labor and material. One thermocouple is placed in the furnace chamber with the sensitive end near the winding and the other is placed inside the revolving cylinder. With a 72 kw. rating, the time of heating to carburizing temp. is from 1.5 to 3.25 hrs. under normal conditions, and the total overall time is always several hrs. less than that required to heat up cold boxes and their contents. Small forgings can be given a  $1/32$ -in. case at 1680° F. in 6.5 hrs. at the rate of 31 lbs. net per kw. hr. The radiation loss at this temp. is approx. 17 kw. hr. H. STOERTZ

**Electrical heating by the container resistance method.** Articles of process equipment become their own heating systems. R. A. CARLETON. *Ind. Eng. Chem.* 21, 525-9 (1929); cf. *C. A.* 22, 1547.—Data are given on heating tubular heaters, kettles, tanks, pipe-lines, forced circulation evaporators and drums or cylindrical heaters; their present application in industry and their cost are compared with other systems.

**Starting Andes Copper's electrolytic and refining plant.** CARR B. NEEL. *Eng. Mining J.* 127, 714-9 (1929).—A description of the electrolytic and refining plant of the Andes Copper Mining Co. at Potrerillos, Chile, operation of which began in July, 1928. N. discusses the equipment, arrangement and early practice in the electrolytic department, where the leach solns. are electrolyzed, with brief mention of the breaking in of the refining furnace.

H. STOERTZ

**The action of limestone and dolomite on zinc sulfate solutions.** L. CAMPI, G. BOZZA AND D. MASPERI. *Giorn. chim. ind. applicata* 11, 3-8 (1929).—In the electrolytic prepn of Zn from  $ZnSO_4$  a neutralizing material such as limestone or dolomite is added to maintain a neutral soln., as well as to ppt. Fe, and to coagulate siliceous material. However, if present in excess, these will ppt. Zn as basic carbonate. The rate of this reaction has been studied at 40° and 100° for both limestone and dolomite, and the consts. of the reactions have been detd. as follows: limestone at 40° —  $K = 0.000282$ ; at 100° —  $K = 0.00124$ ; dolomite at 40° —  $K = 0.0000884$ ; at 100° —  $K = 0.000636$ . It is evident that dolomite reacts with only  $1/3$  the speed and is, therefore, preferable in minimizing losses through pptn. of basic Zn salts.

The electrodeposition of cadmium for rust prevention. S. WERNICK. *Chem. Age* (London), Monthly Met. Section, 20, No. 505, 17-18, No. 510, 27-28(1929).—See C. A. 23, 2369. E. C. M.

Testing of electrodeposits on aluminum. G. B. BROOK AND GEORGE H. STOTT. *Engineering* 127, 531-4(1929); *Metal Ind.* (London) 34, 419-21, 439-41(1929).—See C. A. 23, 2370. E. C. M.

An electrical test for tin coating on copper wire. H. M. LARSEN AND C. M. UNDERWOOD. *Wire* 4, 118-19, 140(1929).—A rapid, inexpensive and accurate method is described, which is claimed to have many advantages over the chem. test for detg. the amt. of deposit. E. I. S.

The single potential of the nickel electrode. EDGAR NEWBURY. *J. Am. Chem. Soc.* 51, 1429-36(1929).—The e. m. f. of a Ni electrode in a soln. of  $\text{NiSO}_4$  depends very little on the purity of the salt or of the metal (except for occluded H), but largely on the method of prepn. of the electrode and whether it is kept in motion. Reproducible values were obtained only when the electrode was rotated and was subjected intermittently to anodic action. The results are explained on the assumption of 2 allotropic forms of Ni and of hydration of Ni ions in soln. T. H. CHILTON.

Rapid copper-plating of steel over a thin deposit of nickel. M. BALLAY. *Rap. métal.* 26, 221-3(1929).—Lab.-scale and semi-com. expts. have shown that Cu-plating of steel in a cyanide bath for 45 mins. could be replaced by Ni-plating for 1 min. followed by Cu-plating for 3 mins. in a hot acid sulfate bath. A bath contg. 400 g. Ni sulfate, 22 g. crystd. Ni chloride, 22 g. boric acid and a trace of Ni nitrate or  $\text{HNO}_3$  per l. and stirred with compressed air, can be used at temps. of 35-55° and at a  $p_H$  value of 5.5-4.4, according to the c. d., which can be as high as 15 amp. per sq. dm. in certain cases; generally, a  $p_H$  of 5.0-5.5 and a temp. of 50° permit of working at 10 amp. per sq. dm. and for parts of very complicated form, the c. d. can be lowered but need very seldom fall below 5 amp. per sq. dm. A treatment of 45-60 secs. is sufficient. A bath contg. 300 g.  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  and 25-30 cc. of 66° Bé.  $\text{H}_2\text{SO}_4$  per l. of water and stirred with compressed air, permits of working at 45° with a c. d. of 10 amp. per sq. dm.; densities up to 30 amp. were used with satisfactory results. The adherence of the double coating is perfect; sheet steel coated in this way can be bent right back on itself or heated to over 900° without causing sepn. A. PAPINEAU-COUTURE

Selection, care and operation of plating. W. S. BARROWS. *Can. Machy.* 40, No 7, 39-40(1929).—Gray-iron gears wear best. E. I. S.

Studies of the electromotive behavior of aluminum and its amalgams. ROBERT MÜLLER. *Z. Elektrochem.* 35, 240-9(1929).—M. finds that the electrode potential of Al is the same as its amalgams up to a concn. of 99.8 at. % Hg, both from measurements of cells contg. amalgams of different concns. measured against a reference electrode and from measurements of the potential necessary to cause the deposition of Al on either Pt or Hg. The mechanism of the reaction of Al with water and acids is discussed, and M. concludes that, although it is impossible to decide how Al reacts with water, it is evident with HCl that Al reacts with the undissocd. mols. of HCl. M. D.

The influence of the solvent on the electromotive force of silver halide cells. I. Water-alcohol mixtures. A. S. AFANASIEV. *Z. Elektrochem.* 35, 220-2(1929).—The equation of Brodskii (C. A. 20, 3377) is further confirmed by data on cells contg. Ag AgCl electrodes instead of calomel electrodes, which Brodskii used. MALCOLM DOLE

Electrolysis of ammonium acetate and ammonium capronate. FR. FICHTER AND WERNER LINDENMAIER. *Helv. Chim. Acta* 12, 559-72(1929).—The electrolysis of  $\text{NH}_4\text{OAc}$  in AcOH solns. with Pt electrodes gives  $\text{C}_2\text{H}_4$  by the regular Kolbe reaction, and also some  $\text{AcNH}_2$ , especially if the anode is well cooled. The formation of  $\text{AcNH}_2$  is attributable to a side reaction between  $(\text{AcO})_2$  and the  $\text{NH}_3$  from either  $\text{NH}_4\text{OAc}$  or  $(\text{NH}_4)_2\text{CO}_3$ . Similarly,  $\text{NH}_4$  capronate yields  $\text{C}_6\text{H}_{11}\text{CONH}_2$ . In  $\text{NH}_3$  soln. and with a graphite anode,  $\text{NH}_4\text{OAc}$  yields  $\text{CO}_2$ , MeOH and a small quantity of  $\text{MeNH}_2$ , the latter in quantity similar to that obtained by the explosion of  $\text{AcOOH}$  in an atm. of  $\text{NH}_3$ . Thermal decompn. of  $\text{AcOOH}$  alone yields MeOH,  $\text{CO}_2$  and  $\text{C}_2\text{H}_4$ , thus explaining the formation of  $\text{C}_2\text{H}_4$  in the electrolysis of  $\text{NaOAc}$ . In  $\text{NH}_3$  soln. and with Pt anode,  $\text{NH}_4\text{OAc}$  yields MeOH and HCHO, the latter reacting further with  $\text{NH}_3$  to give  $\text{MeNH}_2$ , and other bases and amorphous products of high mol. weight. In all cases  $\text{CO}(\text{NH}_2)_2$  is formed, probably by anodic reaction of the  $(\text{NH}_4)_2\text{CO}_3$ . G. C.

Experiments with an electrolytic generator. V. M. SHULGIN. *Physik. Z.* 30, 235-7(1929); cf. *Ibid* 29, 724(1928).—Continuing previous expts. of using a reversed Wehnelt interruptor (Pb anode and Pt cathode) as a source of electromagnetic oscillations, S. was able to show that the pressure of  $\text{H}_2$  at the Pt cathode gave rise to the oscillations. He devised a simple method for keeping the cathode surrounded with

an atm. of  $H_2$ , maintaining the pressure so that the tip of the cathode just dips in the acid. In this way, with a 240 v. input, he was able to get a current of 0.143 amp. in the room antenna, and one of 3.05 milliamp. in the receiving app. On eliminating the self-inductances in the generating circuit, an even greater antenna current was obtained. The same phenomena are observed as with a Tesla coil, so this new method is recommended as a simple and certain method of obtaining high-frequency currents.

LOUIS WALDBAUER

**The nature of gas-metal electrodes.** SIDNEY J. FRENCH AND LOUIS KAHLBERG. *Trans. Am. Electrochem. Soc.* 54, 163-99(1928); *Metal Ind.* (London) 33, 443-6, 543-5, 569-70.—When an Al electrode, freshly sanded, is placed in a soln. of a neutral electrolyte such as KCl, the e. m. f. falls off rapidly during the first 15 or 20 mins., and a const. potential is finally reached 500 or 600 millivolts less than the initial e. m. f. If  $H_2$  or  $N_2$  be now bubbled through the electrolyte around the electrode, the potential, after an initial lag, gradually becomes more basic till a new const. e. m. f. is obtained, 300-400 millivolts more basic than that in air. However, it is not possible to raise the potential of the Al electrode up to the initial e. m. f. of 1.4 v., indicating that the gas and metal form a combination *gas-metal electrode* with a specific potential of its own. The effect of  $O_2$ ,  $N_2$  and  $H_2$  upon 25 different metals was studied, all of them forming gas-metal electrodes. The metals used were Al, Sb, As, Bi, Cd, Cr, Co, Cu, Au, C (graphite), Fe, Pb, Mg, Mo, Hg, Ni, Pd, Pt, Te, Si, Ag, Th, Sn, W and Zn. A few expts. were made with CO,  $CH_4$  and He. The results show in general that gas-metal electrodes are specific for the particular metal and gas, and are related to the absorbing power of the metal for the gas or for each gas in case of a mixt. The total combination potential is due both to absorbed gas and to a condensed film of gas on the surface of the metal.  $O_2$  tends to make the metal potentials less basic, while  $N_2$  and  $H_2$  have the opposite effect. Elements having amphoteric properties and variable valences and which are known to function as catalysts show greater change with  $N_2$  and  $H_2$  than do the more simple and pronouncedly metallic elements. Helium has little effect on potentials, but on Pt and Cd it has a small but definite effect. Coating the electrodes and stirring the electrolyte have the same effect of preventing the condensation of a gas film on the surface of the electrode. The most const. electrodes are those which show the smallest difference between their  $O_2$  and  $N_2$  potentials. The gas-metal electrode potential depends on the gas dissolved in the electrolyte and not on that in the gas phase. H. S.

**A vacuum-arc lamp of new design for spectroscopic work.** KAMTA PRASAD. *J. Sci. Instruments* 6, 126-30(1929).—In this new arc lamp the arc can be struck in vacuum from outside as often as desired and can be run without attention for about an hr. or so at a time. The vacuum seal is so simple that, even if the arc is to be uncovered, the time required in resealing the cover air-tight is very short. Ordinarily the arc works very steadily at about 1 cm. of Hg, but, if desired, the pressure can be further reduced. E. H.

The transport number of aqueous AcOH (MCBAIN, HARVEY) 2. The manufacture of caustic soda (MORIN) 18. Melting Al (BALLY) 9. The manufacture of glass for electric incandescent lamps (TISCHER) 19. Cr-plating steel before heat treating (TOUR) 9. Mg and its alloys (CAZAUD) 9. Cr-plated Cu used as fuse wires or strips (Brit. pat. 300,160) 9. Preparing Si steel sheets for electrical purposes (U. S. pat. 1,714,038) 9. Tar distillation [purifying by elec. discharges] (Fr. pat. 652,109) 21. Deposition of rubber (Fr. pat. 651,730) 30. Device for thermostatic and time-interval regulation of electric furnaces or other apparatus (Brit. pat. 299,714) 1. BERTHIER, AUGUSTE: *L'énergie électrique de demain*. Le problème de la transformation directe de l'énergie chimique potentielle en énergie électrique. La pile au charbon. La pile à gaz et la pile aux hydrocarbures. Théorie et réalisation. Paris: Desloges, Girardot et Cie. 236 pp. F. 40.

**Electric battery.** K. SCHENKEL (to Siemens & Halske A.-G.). Brit. 299,784, Oct. 31, 1927. Plates are formed with a layer of C and a layer of depolarizer, such as  $MnO_2$ , joined together by pressure with a stiffening material, such as linen or paper, extending over at least one surface of the depolarizer and which may serve also to absorb the electrolyte. Rosin melted with the graphite may also be used to stiffen the depolarizer; plaster of Paris and glue also may be used.

**Electric battery assembly.** H. HITCHEN. Brit. 300,003, Oct. 28, 1927. Structural features.

**Storage battery.** V. G. CHERNUKH. Russ. 5756, June 30, 1928. Constructional features are specified.

**Storage battery.** ADRIAN M. CLARK (to Cooper Corp.). U. S. 1,714,077, May 21, 1928. Structural features.

**Storage battery.** WILLIAM E. DUNN (to Electric Storage Battery Co.). U. S. 1,714,467, May 21, 1928. Structural features.

**Storage batteries.** COMPAGNIE GÉNÉRALE D'ÉLECTRICITÉ. Fr. 652,511, Feb. 21, 1928. Construction of connecting elements.

**Storage battery plates.** FRANK GARACA (to Luthy Research Laboratory). U. S. 1,713,825, May 21, 1928. A paste is formed by mixing sulfated active material with a dil. NaOAc soln.; the paste is applied to grids, and the sulfates and acetate are removed from the paste before the forming operation (suitably by electrolysis).

**Drying chamber for battery plates.** JOHN H. STEELE. Australia 15,014, Aug. 11, 1928.

**Salvaging storage-battery electrode material.** CLARENCE B. WHITE. U. S. 1,715,262, May 28, 1928. In order to recover separately the antimonial lead forming the grid frame and the filler material comprising lead oxide and sulfate, the plates are heated to a temp. sufficient to liquefy only the metal portions; the molten metal which flows off is collected; the hot filler material and entrapped molten metal are projected upon a cooler material having a roughened surface to effect liberation of the entrapped metal and disintegration of the filler material, which is separately collected. An app. is described.

**Hydrometer (containing "specific gravity balls") suitable for testing storage battery electrolyte.** J. H. COLLIE. Brit. 299,816, July 18, 1927. Structural features.

**Electrothermal operations.** GRÄFLICH SCHAFFGOTSCH'SCHE WERKE G. M. B. H. Fr. 651,941, Mar. 29, 1928. In electrothermal operations, such as in the production of carbides, silicides and metals from their ores, semi-coke obtained at a temp. lower than coke from cokeries is used as a reducing agent.

**Electrodeposition of metals.** ÉMILE HOORICKX. Fr. 652,619, April 12, 1928. In depositing metals on fragile surfaces such as glass the current conductors are in the form of pads placed on the surface; they are raised or lowered by rotation of a wheel.

**Apparatus for the electrodeposition of a protecting metal on wire.** MARCEL VINCENT. Fr. 652,650, April 13, 1928.

**Electrodeposition of metals such as zinc.** METALLGES. A.-G. (formerly Metallbank und Metallurgische Ges.). Brit. 299,725, Oct. 27, 1927. Smooth and dense deposits are obtained by the addn. to the bath of a hydrophilic inorg. colloid, insol. in the electrolyte, in a suitable state of dispersion and free from assoc. detrimental substances. Small proportions of colloidal silicic acid are suitable for use with a soln. obtained by leaching ZnO not contg. silica with acid ZnSO<sub>4</sub> soln. In refining Cu, colloidal hydrated tungstic acid obtained from Cu tungstate by adding H<sub>2</sub>SO<sub>4</sub> may be used. Metatitanic acid or zirconic acid may be used with acid electrolytes, and Fe(OH)<sub>3</sub> or Mg(OH)<sub>2</sub> with alk. electrolytes.

**Electrodeposition of metals on wood, etc.** I. AINSTEIN (known as W. I. Einstein). Brit. 300,060, Feb. 22, 1928. Wood or other org. material is dipped in sol. glass and its surface is sanded and then dried. A pulverized coating such as an alloy of easily fusible metals comprising Pb, Sb, Bi, Sn and Zn is then applied by a "gun"; a second coating of Cu, bronze, or brass may be applied similarly, followed by electroplatings first in a cold and then in a hot bath.

**Electrodeposition of chromium.** RUDOLF APPEL. U. S. 1,713,514, May 21, 1928. The metallic object to be coated is subjected to electrolysis in a chromic acid bath contg. not more than 0.5 g. per l. of NaIO<sub>3</sub>, which serves to improve adhesion of the Cr to the underlying metal. Cf. C. A. 22, 2116.

**Electrodeposition of chromium.** E. V. HAYES-GRATZE. Brit. 300,043, Jan. 5, 1928. Anodes are used which are formed of pure electrodeposited Cr and which are approx. to the reversed shape of the mold or article to be plated. Various details and modifications are described.

**Electroplating apparatus.** K. BARANOWSKI. Brit. 300,038, Dec. 21, 1927. Brushes preferably made of glass filaments and carrying vanes serve to sweep the electrodes as they rotate on a shaft. Various structural details are described.

**Zinc plating.** GIUSEPPE BIANCO. Fr. 652,112, April 3, 1928. Porous Zn is used in electrolytic Zn-plating baths, e. g., a bath contains porous Zn 100-200, Hg 1-15, H<sub>2</sub>

SO<sub>4</sub> 125-275, double sulfate of Fe and Al 15-40, H<sub>3</sub>PO<sub>4</sub> 5-15, NaOH and KOH 5-15, distd. water 1000 parts by wt.

**Galvanoplastic baths.** H. WINDLER A.-G. Fr. 652,185, April 4, 1928. Means are described for raising and lowering at the same time the anode and cathode.

**Electrolytic baths.** ALEXANDER WACKER GESELLSCHAFT FÜR ELEKTROCHEM. IND. G. M. B. H. Fr. 651,998, Mar. 30, 1928. Diaphragms, filters, or porous substances for electrolytic baths; are formed by agglomerating finely powd. BaSO<sub>4</sub>, quartz, glass, corundum, cinders, or asbestos with solns. or suspensions of gum, gutta-percha, balata, cellulose and cellulose compds., or natural or artificial resins. Metallic cloth may be used as support for the diaphragm.

**Electrolytic refining of aluminum.** ALUMINIUM-INDUSTRIE A.-G. Brit. 299,689, Oct. 25, 1927. An electrolyte is used comprising a halide salt of Al and a halide salt of an alkali or alk. earth metal or both, which are molten at the working temp. at which the anode and cathode remain solid; small quantities (0.1-5%) of Mn, Pb, Cd, or Ni or their compds. are added to the bath directly or by way of inclusion with the anode material. Cf. C. A. 23, 2667.

**Magnesium.** W. KOEHLER. Brit. 300,149, July 29, 1927. Mg ore is heated in an elec. furnace with a gaseous reducing agent such as H or a gas contg. H, which is introduced at such a point that it is ionized; Mg is obtained as vapor. Coal or coke may be added to the ore and when dolomite is used, CaC<sub>2</sub> is also formed and collected. Various details of the app. and process are given. Cf. C. A. 22, 546.

**Phosphorus nitride.** CLAUDE G. MINER. U. S. 1,715,041, May 28. P and N are brought together in proper proportions at a temp. above the b. p. of P but below redness, and the mixt. is subjected to an energetic elec. discharge in a reaction chamber. An app. is described.

**Electric resistance furnace suitable for heat treatment of metal or ceramic ware, etc., in reactive gases.** FRANCIS A. J. FITZGERALD (to Harper Elec. Furnace Corp.). U. S. 1,714,081, May 21. The resistor chamber contains an inert gas and is sepd. from the heat-treating chamber by a septum of material such as Si carbide, which will not deteriorate when heated to a high temp. and which will resist the active gas in the treating chamber. Various structural details are described.

**Electric annealing furnaces.** AKT. GES. BROWN, BOVERI & CIE. Fr. 652,242, April 5, 1928. Method of making the annealing chamber gas-tight. Cf. C. A. 23, 1066

**Furnace for continuous annealing of wire in hydrogen, etc.** ALLGEMEINE ELEKTRICITÄTS-GESELLSCHAFT (to International General Electric Co.). Brit. 300,242, Nov. 9, 1927. Structural features of an elec. resistance-heated furnace.

**Rotary electric furnace with steel electrodes, suitable for activating decolorizing carbon.** L. WICKENDEN and S. A. W. OKELL. Brit. 300,146, July 5, 1927.

**Electrodes for electric furnaces.** SOC. ÉLECTRO-MÉTALLURGIQUE DE MONTRICHER (Soc. anon.). Fr. 652,014, Mar. 31, 1928.

**Medical electrode.** NELSON H. LOWRY and LLOYD F. MEGAW. U. S. 1,713,970, May 21. A conductor such as Pt or a Pt alloy is surrounded by an insulating material such as porcelain having a high m. p. and having about the same coeff. of linear expansion as the conductor. U. S. 1,713,971 relates to the use of Pt Ir alloy electrodes for sterilizing and drying cavities of teeth by discharge from a source of high frequency elec. oscillation as long as such discharge will take place.

**Incandescent cathodes.** SIEMENS & HALSKE A.-G. Fr. 652,017, Mar. 31, 1928. The emission material of incandescent cathodes with high electron emission is composed of an alk. earth, e. g., Ba, or a mixt. or alloy of several such metals. A layer of BaO may be fixed between the support and the metal.

**Incandescent cathode discharge tubes.** NAAMLOOZE VENNOOTSCHAP PHILIPS' GLORILAMPENFABRIEKEN. Brit. 299,704, Oct. 29, 1927. In a discharge tube for low tensions with an arc discharge, a gas filling such as Ar or Ne mixts. is used with a small quantity of Hg vapor; the wall of the lamp is of material transmitting ultra-violet rays. The cathode may be of the Wehnelt type or coated with BaO or otherwise given a high emission at relatively low temp.; it may be heated by the discharge. A device is described adapted for operation at temps. below 100°. Various structural details are described.

**Dielectric material for condensers.** TELEPHON-APPARAT-FABRIK E. ZWIETUSCH & Co., GRS. Brit. 299,697, Oct. 29, 1927. An impregnating or filling material for condensers may be formed of colophony 10 and ozocerite 90%; when the condenser is to be used in contact with steam or subjected to material variation in temp., half of the colophony may be replaced by carnauba wax.

**Electrical condenser.** SAMUEL RUBEN. U. S. 1,714,319, May 21. Cu plate electrodes are used in surface contact with a film-forming electrolyte, which may contain KF in paraffined cotton gauze and which is mixed with Cu particles. Cf. C. A. 23, 2667.

**Electrolytic condenser.** SAMUEL RUBEN. U. S. 1,714,191, May 21. An electrolyte mixt. comprising glycerol,  $\text{NaHCO}_3$  and  $\text{H}_2\text{BO}_3$  is used with spaced film-forming electrodes such as Al sheets coated with an oxide film.

**Apparatus for vacuum impregnation of electrical condensers with wax, oil, etc.** REGINALD H. HOYT (to Wireless Specialty Apparatus Co.). U. S. 1,715,035, May 28.

**Gas-filled electrical discharge device.** CHARLES G. SMITH (to Raytheon, Inc.). U. S. 1,714,402, May 21. Cathodes and anodes are placed in a receptacle filled with a gas and spaced apart by distances which are too short normally to permit of gaseous ionization and conduction; one of the electrodes is provided with openings to permit of long electron paths through it, and a device adjacent to the openings serves to alter the lengthened paths to control the gaseous discharge. U. S. 1,714,403 relates to structural features of elec. gaseous discharge devices. U. S. 1,714,404 specifies a method of controlling the conducting properties of a gaseous medium between 2 electrodes spaced sufficiently close together normally to prevent gaseous ionization, by lengthening the paths of electrons between the electrodes to cause conduction to take place, and by distorting the ionization over a small portion of the electrode surfaces. U. S. 1,714,405 relates to a device with 2 electrodes immersed in gas and spaced apart by a distance comparable to the mean free path of electrons in the gas, together with means for lengthening the electron paths in a direction parallel to the electrode surfaces, and means for altering the effect of the path lengthening means over a restricted portion of the gaseous region between the electrodes. U. S. 1,714,406 specifies an elec. device suitable for use in amplification, etc., comprising a pair of electrodes in a nearly perfect vacuum and various assocd. elec. and structural features. U. S. 1,714,407 relates to a device with an electrode of material such as Na K alloy, which is liquid at ordinary temp., an opposing electrode, and a gas space sufficiently short between the electrodes to prevent substantial ionization by electrons traversing the shortest paths between the electrodes; means are provided to cause electrons to flow longer paths in one direction of applied potential between the electrodes.

**Electrical gas purification plant.** DINGLER'SCHE MASCHINENFABRIK A.-G. Pat. 651,993, Mar. 30, 1928.

**Electric conductivity-testing apparatus for determining the purity of boiler-feed water and other liquids.** H. L. RANGER. Brit. 300,229, Aug. 9, 1927.

**Oscillation generator.** JAMES A. MILLER (one-fourth to John Flam and three-eighths to Harold F. Elliott). U. S. 1,714,689, May 28. A pair of electrodes is cooled to prevent a cond. or arc discharge; a diffused gaseous discharge of a compd. of C and H (or of Si, Se, or Th and H) is produced between the electrodes. Various structural details are described.

**Recording sound by alternating currents.** H. KÖNEMANN. Brit. 299,702, Oct. 29, 1927. In app. for recording sound by a. c. as described in Brit. 291,029, metal oxides are used on metal electrodes of the arc lamp to produce de-ionization by keeping the temp. low. The electrodes may either be coated with the oxide or may themselves be oxidized.

**Electric incandescent lamp.** FRITZ ECKHARDT and MAX HOHNEKAMP. U. S. 1,713,752, May 21. A shunt permanently connected to the ends of the filament comprises a sulfide such as galena, which is non-conductive when the normal voltage is applied to the lamp but conductive if a higher voltage is applied; it serves as a safety device for lamps connected in series. Cf. C. A. 22, 2518.

**Lamps containing ionizable gases.** GEORGES MABBOUX. Fr. 651,879, Mar. 27, 1928. Means for varying the distribution of electrostatic charges on the electrodes.

## 5—PHOTOGRAPHY

C. E. K. MEES

**Chemistry of reduced silver.** I. R. NAMIAS. *Il prog. fot.* 36, 115-8(1929).--The general chemistry of the developed image is described. The nature of light-sensitivity of photographic materials, optical sensitizers and desensitizers, and some notes on the nature of developing agents are given.

**Application of the noble metals in photographic chemistry.** W. NODDACK. *Metallwirtschaft* 7, 477-9(1928).--A general discussion of the chem. and catalytic changes

in the salts of Ag, Hg, Pt, Au and other metals produced by light, with particular reference to the employment of these in photography and the photographic industries. There is a brief discussion of the basic theories. Minor attention is given to the reactions of other metals such as Os, Ru and Ir.

C. L. MANTELL

**Sensitivity of photographic emulsions.** III. S. O. RAWLING. *Phot. J.* 69, 83-93 (1929); cf. *C. A.* 21, 863.—The effect of altering the acidity of an emulsion during digestion on the final sensitivity is examd. The depression caused by decreasing the  $p_H$  in emulsions contg. sensitizing nuclei is similar to those made with desulfurized gelatin. Two factors evidently control sensitivity: the degree of nucleation and the H-ion concn. The effect of  $p_H$  alteration is independent of the mode of making of the emulsion whether  $NH_4OH$  or heat ripening is employed, or whether AgI is present, but is a characteristic of the gelatin used. When an emulsion is divided into 2 parts and ripened at different  $p_H$  values, the alteration of speed with digestion follows 2 widely sep'd. paths. Emulsions ripened at  $p_H$  8 are initially faster and increase in speed, while those maintained at  $p_H$  5 are slow and may become slower. An emulsion prepd. at a low  $p_H$  and raised to a high does not attain the full speed of the high  $p_H$  emulsion. Similarly, an emulsion prepd. at a high  $p_H$  is not depressed fully by conversion to a low  $p_H$ . The ratio of fall from high  $p_H$  is approx. equal to rise from low. Within the limits  $p_H$  5 —  $p_H$  8.5 the fog remains unchanged.

K. C. D. HICKMAN

SCHMIDT, FRITZ: *Kompndium der praktischen Photographie*. 15th ed., revised. Leipzig: E. A. Seemann. 516 pp. Linen, M. 15.

URBAN, WILHELM: *Theoretisch-praktischer Leitfaden durch das Gebiet der Phototechnik*. Stuttgart: Verlag Ferdinand Enke. 348 pp. M. 8; linen, M. 9.50.

**Color cinematography.** O. PILNY (to A. Pilny). *Brit.* 300,210, Nov. 8, 1927. Optical features.

**Stereoscopic photography.** L. F. SAVAGE. *Brit.* 299,733, April 30, 1927. Optical features.

**Photographic developers.** B. MEREJKOVSKY. *Brit.* 299,751, June 29, 1927. To a developer contg. a polyphenol with 2 or more OH groups and no  $NH_2$  group (such as hydroquinone or pyrogallol) together with hydroxylamine sulfonic acids or nitrilosulfonic acid or their salts, there is added, as an accelerator, a very small quantity of a primary diamine or a secondary amine such as piperidine, methylaniline, methylparaamidophenol, amidol or like compds.

**Combined photographic developer and desensitizer.** HERBERT MEYER (to Agfa Ansco Corp.). U. S. 1,713,613, May 21. A developer is prepd. comprising Hg cyanide, methyl-*p*-amino-phenol sulfate and hydroquinone; it serves to avoid fogging during development in proper lighting.

**Sensitized paper.** ZAIDAN HOJIN RIKAGAKU KENKYUJO. *Fr.* 652,008, Mar. 30, 1928. A positive sensitized paper is obtained by coating paper with an aq. soln. of a tetrazodiaminodiphenylamine compd., or a diazoamidodiphenylamine compd. or derivs. of these, this soln. being mixed with an org. or inorg. acid, and with or without the addn. of an azo dye, and drying the paper. Examples are given.

**Cinematographic films.** PALMIRE H. NICOLIC and MAURICE J. E. CLAUDE. *Fr.* 33,724, Apr. 6, 1927. Addn. to 635,828. The conducting coating of the prior patent is incorporated with an adhesive coating or varnish before its application to the film, or is deposited on such a coating applied to the film. Cf. *C. A.* 23, 1831.

**Printing title indicia, etc., on films or negatives.** SAMUEL E. KELLOGG. U. S. 1,713,360, May 21. The negative is placed with the emulsion side next to an impression of the indicia; a protecting material such as paper is placed against the negative and pressure is applied to the protecting material by means of the indicia type and with the type in register with the indicia.

## 6—INORGANIC CHEMISTRY

A. R. MIDDLETON

**Advances in inorganic chemistry since 1925.** WILHELM KLEMM. *Z. angew. Chem.* 42, 467-79, 494-501 (1929).

**The preparation of beryllium chloride from beryl.** R. W. WINTERS and L. F. YNTEMA. *Trans. Am. Electrochem. Soc.* 55 (preprint) 3 pp. (1929).—An intimate mixt.

of powdered beryl and carbon was heated in a retort to  $800^{\circ}$  in a stream of  $\text{CCl}_4$  and  $\text{Cl}_2$ .  $\text{BeCl}_2$  was condensed at a temp. above the boiling points of  $\text{AlCl}_3$  and  $\text{SiCl}_4$ . C. G. F.

**The decomposition of sodium sulfate.** GERMAINE MARCHAL. *Bull. soc. chim.* 45, 225-8 (1929).— $\text{Na}_2\text{SO}_4$  is very slowly decompd. by heat alone even at  $1300^{\circ}$ . Addn. of  $\text{SiO}_2$  or of relatively smaller proportions of  $\text{Al}_2\text{O}_3$  promotes the decompn.; the latter reaction may serve as a method of *producing alumina*. T. H. CHILTON

**Strontium thiosulfate.** R. PORTILLO. *Anales soc. españ. fís. quim.* 27, 243-50 (1929).— $\text{SrS}_2\text{O}_3$  was obtained by double decompn. of  $\text{SrCl}_2$  and  $\text{Na}_2\text{S}_2\text{O}_3$ . Recrystn. from alc. gives very pure  $\text{SrS}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ . In the air it loses 4  $\text{H}_2\text{O}$  mols. The last  $\text{H}_2\text{O}$  mol. is not lost even on heating to  $180^{\circ}$ . It has  $d_{25} = 2.202$ .  $\text{SrS}_2\text{O}_3 \cdot \text{H}_2\text{O}$  has a  $d_4^{25} = 2.916$ , showing  $V_m$  of  $\text{H}_2\text{O} = 14.22$ . The soly. of  $\text{SrS}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$  at 0, 12.8, 27.5,  $40^{\circ}$  is 8.78, 13.82, 21.10, 26.80%, resp.; mol. heat of soln.,  $Q = -7.34$ ; for  $\text{SrS}_2\text{O}_3 \cdot \text{H}_2\text{O}$   $Q = +2.38$ . The heat of hydration of  $\text{SrS}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ , starting from  $\text{SrS}_2\text{O}_3 \cdot \text{H}_2\text{O}$ , is  $+9.7$  cal. E. M. SYMMES

**Notes on the molybdates.** V. GÓMEZ ARANDA. *Anales soc. españ. fís. quim.* 27, 251 (1929); cf. C. A. 23, 3180.—Gray, reheated Pb molybdate had a  $d_4^{25} = 6.693$ ; E. M. SYMMES

**The tetrathionates.** I. Barium tetrathionate. R. PORTILLO. *Anales soc. españ. fís. quim.* 27, 236-42 (1929).—Very pure  $\text{BaS}_4\text{O}_{12} \cdot 2\text{H}_2\text{O}$  was obtained by the Fordos and Gelis method (*Compt. rend.* 15, 920 (1842)) by allowing I to react on  $\text{BaS}_2\text{O}_3$ .  $\text{BaS}_4\text{O}_{12} \cdot 2\text{H}_2\text{O}$  is rather stable in the air, does not lose  $\text{H}_2\text{O}$  of crystn. even if heated to  $40$ - $50^{\circ}$ , above this temp. it decomposes. Aq. solns. of  $\text{BaS}_4\text{O}_{12} \cdot 2\text{H}_2\text{O}$  are very unstable even at ordinary temp., but aq.-alc. solns. are very stable.  $\text{BaS}_4\text{O}_{12} \cdot 2\text{H}_2\text{O}$  has  $d_{25} = 2.777$ , soly.  $0^{\circ} = 26.5$ ;  $12.8^{\circ} = 29.8$ ;  $27.5^{\circ} = 36\%$ , mol. heat of soln. at  $17^{\circ}$ , 800 mol.  $\text{H}_2\text{O} = -7.00Q$ . E. M. SYMMES

**The reaction of sulfur dioxide with nitrogen dioxide.** W. MANCHOT AND H. SCHMID. *Ber.* 62B, 1261-3 (1929); cf. C. A. 21, 477.—The authors confirm the work of Briner, *et al.* (C. A. 23, 1584), that the compd.  $2\text{SO}_2 \cdot \text{N}_2\text{O}_3$  (I) is formed by the reaction of  $\text{SO}_2$  on either  $\text{NO}_2$  or  $\text{N}_2\text{O}_3$  as well as by the action of  $\text{SO}_3$  on  $\text{NO}$ . These last 2 gases first undergo an oxidation-reduction reaction. It was attempted to prove that  $\text{NOOSO}_2\text{ONO}$  first formed, 2 mols. of which then lose  $\text{N}_2\text{O}_3$  to give I. I on the heating loses  $\text{N}_2\text{O}_3$  to give  $(\text{ONOSO}_2\text{OSO}_2)_2\text{O}$ . The loss of water by 2 mols. of nitrosylsulfuric acid indicates that the chamber process is not as complicated as is believed. V. F. H.

**The preparation of hypophosphoric acid by the action of sodium hypochlorite on red phosphorus.** JOHANNES PROBST. *Z. anorg. allgem. Chem.* 179, 155-60 (1929); cf. C. A. 22, 198.—The method is a modification of Speter's method of prepg.  $\text{NaHPO}_3 \cdot 3\text{H}_2\text{O}$ . Red P is added at  $5^{\circ}$  to a soln. of  $\text{NaOCl}$  with mech. stirring. The yield is 25%. A new method of detn. of hypophosphoric acid is given depending upon the pptn. of its Ag salt and on the subsequent conversion of the latter into  $\text{AgCl}$ . EMIL KLARMANN

**The behavior of amorphous carbon and sulfur compared with the behavior of diamond and of graphite and the carbon disulfide of Ciusa.** J. P. WIBAUT AND E. J. VAN DER KAM. *Proc. Acad. Sci. Amsterdam* 32, 501-11 (1929).—See C. A. 22, 2892. E. C. M.

**The existence of an oxide of bromine.** BERNARD LEWIS AND H. J. SCHUMACHER. *Z. physik. Chem., Abt. A*, 138, 462 (1928).—When  $\text{Br}_2$  and  $\text{O}_2$  are allowed to mix in a flask, a white deposit appears on the walls of the flask, and soon thereafter an explosion destroys the app. The white deposit is thought to be an oxide of  $\text{Br}_2$ . R. J. H.

**The index of coordination in 5 hydrates.** F. SIERRA. *Anales soc. españ. fís. quim.* 27, 220-7 (1929).— $\text{ZnSO}_4 \cdot 6\text{H}_2\text{O}$  was obtained by evapn. of a cold, satd. soln. of  $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$  on a bath at  $45$ - $50^{\circ}$ . The mass of small crystals should be sepd rapidly from the mother liquor by filtering on a Schott funnel. Analysis agrees with theory. Dried by a current of very dry air,  $\text{ZnSO}_4 \cdot 6\text{H}_2\text{O}$  loses 5 mols. of  $\text{H}_2\text{O}$  even at  $50^{\circ}$ . The last mol. of  $\text{H}_2\text{O}$  is lost only above  $150^{\circ}$ .  $\text{ZnSO}_4 \cdot 6\text{H}_2\text{O}$  has a  $d_4^{25} = 2.0537$  and a mol. vol.  $V_m = 131.1$ ; therefore  $V_m = 15$  for the first 5  $\text{H}_2\text{O}$  mols. and  $V_m = 9.7$  for the other. This agrees with Moles that it is a question of a pentahydrate cation salt, the other  $\text{H}_2\text{O}$  mol. being attributed to the anion, or  $\text{Zn}(\text{H}_2\text{O})_5(\text{SO}_4 \cdot \text{OH}_2)$ . Prepn of  $\text{ZnSO}_4 \cdot 6\text{H}_2\text{O}$  by desiccation of  $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$  at  $40$ - $50^{\circ}$  is useless because  $\text{ZnSO}_4 \cdot 6\text{H}_2\text{O}$  loses 5 mols. of  $\text{H}_2\text{O}$  even at this temp. E. M. SYMMES

**The dissociation of hydrated metallic nitrates.** J. GARCÍA VIANA AND E. MOLES. *Anales soc. españ. fís. quim.* 28, 157-64 (1929).—Beyond certain limits  $\text{H}_2\text{O}$  cannot be removed from hydrated metallic nitrates without loss of  $\text{N}_2\text{O}_5$ . How far this behavior is in accord with the existence of an orthonitric acid,  $\text{H}_2\text{NO}_4$ , has been investigated in a systematic dehydration of  $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$  and  $\text{Ni}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ . A  $\text{N}_2\text{O}_5$  loss is

not encountered as long as 2 mols. of  $H_2O$  are present, *i. e.*, if the compn. corresponds approx. to the ortho-acid.

**The Ditte reaction.** L. RODRÍGUEZ PIRE. *Anales soc. españ. fís. quim.* 27, 192-219 (1929).—The reaction  $5 CO + I_2O_5 = 5 CO_2 + I_2$ , used frequently to detect and oxidize traces of CO, was first proposed by Ditte (*Ann. Chim. Phys.* 13, 318 (1870)). It is proposed to call it the Ditte reaction. In spite of numerous modern articles on this reaction, there is now no quant. study of it. Also, rather contradictory data are found in the literature regarding temp. and other conditions. The reaction of very pure components was studied. The CO was made by dehydrating  $HCOOH$  by  $H_2SO_4$  in the cold *in vacuo*.  $I_2O_5$  was made by dehydrating  $HIO_3$  obtained by oxidizing I by fuming  $HNO_3$ , the only method which gives a product sufficiently stable and free from  $SO_3$  in the form of  $3I_2O_5 \cdot SO_3$ . Contrary to data in the literature, the Ditte reaction can occur even at  $0^\circ$  and is practically quant. if passage of the gas is slow enough. In desiccation of  $HIO_3$  2 periods were found at  $110^\circ$  and  $200^\circ$ , which confirms the Baxter and Tilley data (*C. A.* 3, 1124). Also, dry  $I_2O_5$ , subjected to a current of dry air, loses not exceeding 0.00006 g. per hr. Quant. oxidation of CO depends mainly upon velocity of the CO current,  $k$  being  $0.7 \times 10^{-4}$  at  $100^\circ$  and  $8.5 \times 10^{-4}$  at  $25^\circ$  and less than 3% at  $0^\circ$ . Increase in unoxidized product at low temp. can be attributed to the action of free I liberated but not entrained by the gas current, forming an insulating layer on the  $I_2O_5$ . The reaction is isothermic. Direct decompn. of  $I_2O_5$  does not take place below  $270^\circ$ . Preliminary tests to det. the  $5CO:I_2:5CO_2$  ratio give encouraging results, showing that the method can be improved.

R. M. SYMMES

**Complex salts of dimethylglyoxime.** J. V. DUBSKÝ AND FR. BRYCHTA. *Pub. Faculty Sci., Masaryk Univ., Brno* No. 103(1928); *Czechoslov. Chem. Comm.* 1, 137-54(1929).—The following new derivs. of dimethylglyoxime have been prepd. ( $DH_2$  being used as an abbreviation for  $(CH_3)_2C_2(NO_2)_2$ ):  $DH_2 \cdot NiCl_2 \cdot 2H_2O$ ,  $DH_2 \cdot NiBr_2$ ,  $(DH_2)_2 \cdot NiBr_2$ ,  $(DH_2)_2 \cdot NiI_2 \cdot I_2$ ,  $(DH_2)_2 \cdot CoCl_2 \cdot 2H_2O$  and  $(DH_2 \cdot CoDH)Cl$ . Attempts to prep. the analogous nitrates and sulfates failed, because of the decompn. of dimethylglyoxime by  $HNO_3$  and  $H_2SO_4$ . Attempts to obtain  $COCl_2 \cdot DH_2$  derivs. with  $C_2H_5 \cdot (NH_2)_2$  also failed on account of their great soly.  $DH_2 \cdot CuCl_2 \cdot xH_2O$  and  $(DH_2)_2 \cdot CuCl_2$  probably do not exist.  $CaCl_2$  and  $ZnCl_2$  do not form addn. products with  $DH_2$ . The structures of the various addn. products were explained in terms of the Werner theory.

FOSTER, WM.: **Inorganic Chemistry for Colleges.** A Textbook for Second-Year Students. New York: D. Van Nostrand Co., Inc. 838 pp. \$3.90. Reviewed in *Chemicals* 31, No. 23, 6(1929).

## 7—ANALYTICAL CHEMISTRY

W. T. HALL

**Hydrogen assay for tin ore.** WM. H. R. ALLEN. *Mining Mag.* 40, 25(1929).—The sample is mixed with  $CaO$  and reduced with H at red heat. After cooling in H, the crucible is treated with a few drops of  $H_2O$  and 30 cc. of concd.  $HCl$  to dissolve the Sn. The Sn is then cemented on Al ribbon and the resulting sponge of Sn and Al redissolved in  $HCl$ . The flask is filled with  $CO_2$  and titrated with a standard I soln. W, Sb, Bi, Cu and As must be removed before titration, if present.

A. BUTTS

**The determination of minute quantities of iodine.** E. GLIMM AND J. ISENBRUCH. *Biochem. Z.* 207, 368-76(1929).—A special app. has been designed for the detn. The substance to be analyzed is placed in a glass-stoppered flask into which a separatory funnel is fused, discharging its contents at the bottom of the flask. Through a side arm it communicates with a special absorption bottle contg. 2%  $KOH$ . A current of air is passed through the entire app., which is at first taken through 2 wash bottles filled with glass wool soaked in  $KOH$ . The flask is suspended in a paraffin bath. The temp. is brought up to  $40-60^\circ$  when 20-25 cc. concd.  $H_2SO_4$  per g. of substance is allowed to run in from the separatory funnel, then 30%  $H_2O_2$ . This generates a very vigorous reaction and the temp. rises to  $90^\circ$ . The addn. of  $H_2O_2$  must be carefully controlled so as to insure a uniform evolution of gas. The air is now drawn slowly through the app. and the temp. of the bath is raised to  $220-230^\circ$ . The distn. is continued for about an hr. The alk. contents of the absorption bottle are evapd. to dryness in a Pt dish. In the method proposed, so little volatile fatty acid is formed and absorbed by the  $KOH$  that the removal of their soaps is easily attained by gentle heating of the dry residue. Or a more complete removal is effected by dissolving the residue after the incineration in

a few drops of  $H_2O$ , evapg. to dryness and heating once more to a dull redness. The residue upon cooling is now extd. with a few cc. of alc. The alc. is evapd. in a small porcelain dish on a water bath. The small residue of salt is transferred with a few cc. of  $H_2O$  to a 30-cc. crucible, acidified with  $HCl$  and treated with a few drops of  $Br_2$  water. It is heated, then, to insure that every trace of free  $Br_2$  is driven off, whereby the vol. is reduced to 1-2 cc. Upon the addn. of a tiny grain of  $KI$  the soln. is titrated with a freshly prepd. 0.002 or 0.001  $N Na_2S_2O_3$ . S. MORGULIS

Two new methods for the volumetric estimation of combined iodine. FRANZ VIEBÖCK. *Pharm. Monatsh.* 10, 59-63(1929).—The methods now commonly used in the volumetric estn. of iodides are discussed in considerable detail, as also 2 procedures involving, in principle, titration of the properly dild. and measured iodide in  $H_2O$  with  $Br$  aq. in the presence of  $CCl_4$ , whereby all the iodide is finally converted into iodate, then titration of the pptd.  $I$  with 0.1  $N$  thiosulfate after addn. of  $KI$  and  $AcOH$ . W. O. E

Shortening the time of nitrogen determinations by the use of the grid burner. H. D. SPEARS AND W. G. TERRELL. *J. Assoc. Official Agr. Chem.* 12, 250-1(1929); cf. Shedd, C. A. 22, 202.—With  $Cu$  as catalyst and natural gas as source of heat, Kjeldahl digestion of materials such as feeding stuffs required only 1.5 hrs. with a grid burner (Fischer), instead of 3 hrs. required with a Bunsen burner. A. PAPINEAU-COUTURE

Progress in analytical chemistry of metals during 1926. HENRYK WDOWISZEWSKI *Przemysl. Chem.* 13, 53-60(1929).—A review with bibliography of new methods for  $Sb$ ,  $As$ ,  $Be$ ,  $Cr$ ,  $Sn$ ,  $Zn$ ,  $Al$ ,  $Cd$ ,  $Mn$ ,  $Cu$ ,  $Mo$ ,  $Ni$ ,  $Pb$ ,  $Hg$ ,  $U$ ,  $V$ ,  $W$  and  $Fe$ . A. C. Z.

Determination of small quantities of the free and organically combined carbon in an inorganic substance. DRAGUTIN STROHAL. *Archiv. chem. farm.* 3, 63-71 (71-2, in German) (1929).—For the detn. of  $C$  in soil it is recommended to heat 5-10 g. of  $H_3PO_4$ -treated and air-dried substance in a combustion tube contg.  $KClO_3$  and  $MnO_2$  mixt. (1:2), (to furnish  $O_2$ ), an asbestos plug, coarse  $CuO$  and another plug. Directions for properly regulating the  $O_2$  supply and for carrying out the method are given in detail. J. K

The separation of ruthenium and osmium and the use of benzene in the iodometric titration of osmium. SHŌICHIRO SAITŌ. *Bull. Inst. Phys.-Chem. Research* (Tokyo) 8, 164-79(1929); *Abstracts* 2, 23-5. (In English).—Expts. on the sepn. of  $Os$  and  $Ru$  either alone or with other metallic elements have shown that:  $Os$  distills off completely on boiling a sample with  $HNO_3$  stronger than 6  $N$  if the element is present in a form sol in  $HNO_3$ . By the same treatment  $Ru$  behaves variously on distn. according to how the element is present: (a) no  $Ru$  distils from the soln. of the sulfide in aqua regia; (b) a little  $Ru$  distills from a distillate of  $RuO_4$  obtained by distg. with  $Cl_2$ , receiving in  $HCl$  and  $EtOH$ , and evapg.; (c)  $Ru$  can be distd. more completely from the melt obtained by fusing with  $Na_2O_2$  and leaching with  $H_2O$ .  $Os$  distills completely, but  $Ru$  does not at all, on boiling a  $HCl$ -soln. of about 1  $N$  in  $HCl$ , which has been made by acidifying (a) an alk. soln. contg. the distillate from the  $HNO_3$  distn. described above, or (b) an aq. soln. of the mass resulting from the fusion with  $Na_2O_2$ . The latter soln. must, however, be allowed to stand for at least a few mins. before boiling, after it has been acidified with  $HCl$ ; otherwise, a very small quantity of  $Ru$  may distil from the soln. For the detection and estn. of a small quantity of  $Os$ , the color of the  $NaOH$  soln. in the receiver in the distn. with  $HCl$ , or the ppt. produced by  $H_2S$  from hot soln. in a pressure bottle, is far more reliable and accurate than those ppts. produced in the same  $NaOH$  soln. mentioned above by means of  $HCl$  and  $H_2S$ , or  $HCl$  and  $Na_2S_2O_3$ . For the same purpose with regard to  $Ru$ , the ppt. produced by  $H_2S$  from hot soln. in a pressure bottle, or the color produced by  $RuO_4$  either in aq.  $NaOH$  soln. or in a mixt. of  $HCl$  and  $EtOH$ , is more reliable and accurate than the color produced in the soln. of  $Ru$  salt by means of  $KCNS$ , or  $NH_4OH$  and  $Na_2S_2O_3$ , or  $KNO_3$ ,  $EtOH$  and  $(NH_4)_2S$ . In the iodometric titration of  $Os$  described by Klobbie, the end point of the reaction between  $I_2$  and  $Na_2S_2O_3$  is very hard to observe exactly by using starch soln. as outside indicator. Benzene alone has been found to be suitable as inside indicator, by means of which the end point can be accurately observed. G. CALINGAERT

Methods for determining silicon in steel, pig iron and the ferrosilicons. R. P. HUDSON. *Heat Treating and Forging* 15, 446-7(1929); cf. C. A. 22, 1746.—A review. E. H.

Tin assay. H. R. BERINGER AND A. F. H. STEPHENS. *Mining Mag.* 39, 360-1 (1928).—Improvements in the Beringer method of reduction of  $Sn$  from its oxide by  $Zn$  vapor are described. A. BUTTS

A simple and reliable test for tinstone. H. V. ELLSWORTH. *Can. Mining J.* 50, 354(1929).—The test described is based on the fact that  $Sn$  oxide in contact with  $Zn$ , which is being acted on by acid, is reduced to metallic  $Sn$ . Common sheet  $Zn$  can be

used, and the acid may be  $\text{HCl}$  or  $\text{H}_2\text{SO}_4$ , preferably the former, because it attacks  $\text{Zn}$  readily in the cold. Common solid acids such as tartaric, citric and oxalic acids attack  $\text{Zn}$  slowly. The test is not quant. E. I. S.

**The determination of iodoform.** ADOLF JÁNSKÝ. *Časopis Českoslov. Lékařnictva* 8, 215-21(1928).—For the detn. of  $\text{CHI}_3$ , J. recommends the volumetric method of Gane and Webster (*C. A.* 3, 1669) based on the sapon. of  $\text{CHI}_3$  with  $\text{NaOH}$  and on the titration of the iodide formed by Volhard's method, taking precautions against the presence of  $\text{Cl}^-$  in the  $\text{NaOH}$ . Another method, which is also suitable for the analysis of gauze contg.  $\text{CHI}_3$ , depends on the reduction of  $\text{CHI}_3$  by  $\text{Zn}$  in a satd. alc. soln. of  $\text{NaOH}$  at an elevated temp. and on the potentiometric titration of the iodide formed. Although the method just described is more precise, J. has recommended for the pharmacopeia a simpler method based on the direct reaction between  $\text{CHI}_3$  and  $\text{AgNO}_3$  in alc. soln. in the presence of  $\text{HNO}_3$ . WILLIAM J. HUSA

**The volumetric determination of phosphoric acid.** WM. H. ROSS. *J. Assoc. Official Agr. Chem.* 12, 170-6(1929); cf. *C. A.* 22, 2433.—Collaborative investigation of the effects of sulfates on the detn. of  $\text{P}_2\text{O}_5$  (pure  $\text{KH}_2\text{PO}_4$  and standard Tennessee phosphate rock were used) by the volumetric method confirmed the view that the presence of  $\text{SO}_3$  seriously interferes when pptn. is made at  $45-50^\circ$ , giving results that are too high, but that the interference is slight when pptn. is made at room temp. with stirring. As the rate of pptn. and compn. of the phosphomolybdate ppt. vary with the temp. of the soln. to which the molybdate is added, a temp. of  $30^\circ$  should preferably be adopted. A. PAPINEAU-COUTURE

**Separation of silver chloride, bromide and iodide.** Application to the determination of bromides, mixtures of chlorides and bromides and of mixtures of chlorides, bromides and iodides. H. LESTRA. *Bull. sci. pharmacol.* 36, 209-21(1929).—In 100 cc. of a soln. contg. 0.80 g.  $\text{NH}_3$  it is possible to ppt. the bromides as  $\text{AgBr}$  while the chlorides remain in soln. In a soln. contg. 60 cc. of official  $\text{NH}_3$  in 100 cc.,  $\text{AgI}$  is pptd., without including  $\text{AgBr}$ . For the titration of the halogens the method of Denigès with a soln. of  $\text{AgNO}_3$  in  $\text{KCN}$  is used. For bromides alone, dissolve 1 g. and fill to 100 cc.; take 10 cc., add 4 cc. of  $\text{NH}_3$ , and  $\text{H}_2\text{O}$  to make about 80 cc. Add 10 cc. 0.1  $N$   $\text{AgNO}_3$ . Fill to 100 cc. Shake and filter; take 50 cc., add 5 cc. 0.1  $N$   $\text{KCN}$ , some drops of  $\text{KI}$  soln. and titrate with 0.1  $N$   $\text{AgNO}_3$  until a persistent turbidity appears. In a mixt. with chloride det. first the  $\text{Cl}$  and  $\text{Br}$  by Mohr's method. Then proceed as for  $\text{Br}$  alone. In a mixt. of chlorides, bromides and iodides use Mohr's method first. Use the method as for bromide alone, maintaining the  $\text{NH}_3$  content at 0.80%. This gives  $\text{Br}$  and  $\text{I}$ . The same process with a soln. contg. 60% of official  $\text{NH}_3$  gives  $\text{I}$ . A. E. M.

**Report on (the analysis of) caustic poisons.** C. M. SMITH. *J. Assoc. Official Agr. Chem.* 12, 141-4(1929).—The Chapin method (*C. A.* 14, 2772) was found satisfactory for the detn. of phenol in such products as sapond. cresol solns., coal tar dips, disinfectants, fly sprays, etc. The results, however, are about 10% lower than the theoretical. A. PAPINEAU-COUTURE

**Accidental poisoning by hydrocyanic acid.** E. KOHN-ABREST. *Ann. méd. légale criminol. police sci.* 9, 132-5(1929).—In cases of death by  $\text{HCN}$ , the latter very rapidly disappears. It is frequently, but by no means always, partially converted during putrefaction into stable thiocyanates, from which the  $\text{HCN}$  can be regenerated and identified and detd. The results of several post-mortem examns. carried out 4-15 days after death gave 0-0.75 mg. "free"  $\text{HCN}$  and 0-4.15 mg. combined  $\text{HCN}$  in the viscera. As  $\text{HCN}$  is destroyed in the course of its action on the organism, it cannot be detected unless the amt. absorbed is greater than the lethal dose. A. P.-C.

**The use of organic reagents for the identification of cations.** ARMANDO NOVELLI. *Rev. Jurm.* (Buenos Aires) [2], 2, 108-20(1929).—A complete survey is given of the reaction of metals with org. substances suitable for qual. or quant. analytical use. A. E. MEYER

**Notes on some tests for acetone and aldehyde.** HENRY LEFFMANN. *Am. J. Pharm.* 101, 337-40(1929).—A review and discussion of proposed tests for acetone and aldehyde (cf. *C. A.* 12, 2180; 15, 1324; 18, 879; 19, 1877; 21, 721). Many of the descriptions of tests for acetone and aldehyde make no mention of interferences, especially no statement whether aldehyde masks or simulates acetone, and similarly with the tests for aldehyde. A study was made of some recently proposed procedures to det. whether simulation also occurs, since several of the familiar tests for one of these give similar results with the other. As a result of these trials, it seems that the newer reagents have no great advantages either for delicacy or certainty. The alkali-vanillin test is quite sufficient for routine clinical work, and salicylaldehyde is even more delicate. W. G. GAESSLER

**Studies on methods. IX. Combined determination of halogens in organic substances.** LUDWIG PINCUSSEN and WADIM ROMAN. *Biochem. Z.* 207, 416-25(1929); cf. *C. A.* 21, 3920.—The dry substance is fused in a Ni crucible with five times the quantity of KOH, whereby the org. matter is all destroyed and all halogen is converted to K salts. The fused mass is leached with  $H_2O$  and the KI is extd. with alc. after evapn to dryness. After removing the alc., the residue is acidified with  $HNO_3$  and with  $KMnO_4$ , the traces of org. matter are oxidized and the iodide is changed to iodate. The  $HNO_3$  is boiled off, the residue dissolved in  $H_2O$  and decolorized with charcoal. The clear filtrate is treated with HCl, KI and starch, the liberated  $I_2$  being titrated with 0.001-0.002  $N Na_2S_2O_3$ . The residue after the alc. extn. is dissolved in  $H_2O$  and transferred to a 50-cc. flask. The  $Br_2$  is detd. by setting it free with  $H_2O_2$ , acidifying with  $HNO_3$  and extg. it with  $CHCl_3$  by shaking. The  $CHCl_3$  ext., washed with ice-cold NaCl soln. to remove every trace of oxidizing substance, is treated with KI, and the amt of  $I_2$  set free by Br is detd. by thiosulfate titration. The Br and Cl contents of the soln. are detd. by the regular Volhard titration, the Cl being calcd. by subtracting the Br value from the Br + Cl combined value. The method yields quick and accurate results. S. MORGULIS

**Report on chemical methods for reducing sugars.** R. T. JACKSON. *J. Assoc. Official Agr. Chem.* 12, 166-9(1929); cf. *C. A.* 22, 2529.—The time consumed and troubles caused by neutralizing the soln. with  $NH_3$  in the detn. of Cu by the  $Na_2S_2O_3$  method are very readily overcome by neutralizing with NaOH to a faint turbidity of  $Cu(OH)_2$  and then clearing by adding 1-2 drops AcOH. In the Lane and Eynon volumetric method, with methylene blue as internal indicator, it was found that variations of as much as 2 mins. from the normal boiling period produced almost negligible variations in the titration results; in the titration, instead of adding the sugar soln. in 10-cc. portions, as specified in the A. O. A. C. method, which tends to cause the analyst to overrun the end point, equally accurate results can be obtained by adding the sugar soln. rapidly in indefinite vols. in the usual manner of titration until the faintest perceptible blue remains, then adding the indicator and completing the titration. It was found that Nyns' method for the detn. of levulose (*C. A.* 19, 1236) is not perfectly selective, 13 mg. of dextrose pptg. the same wt. of Cu as 1 mg. of levulose; the detn. of the dextrose correction for an unknown mixt. involves a complicated and laborious calcn. for neither dextrose nor levulose can be detd. until both are known simultaneously, but it has been found possible to construct a "nomogram" from which the ratio of levulose to total sugar can be read directly, and which will soon be published in the *Bur. of Standards J. of Research*. A. PAPINEAU-COUTURE

The Ditte reaction (PIRE) 6. The recovery of pyridine and phenol from raw C.H. (PIETERS, MANNENS) 21. The use of vitrified silica apparatus for the determination of metals as sulfates (GUNTZ, BARBIER) 1.

JANDER, G. AND PFUNDT, O.: Die chemische Analyse. XXVI. Die visuelle Leitfähigkeitstiteration und ihre praktischen Anwendungen. Stuttgart: Ferdinand Enke. 64 pp. 9s. Reviewed in *Analyst* 54, 310(1929).

## 8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIRER

**An investigation into the piezoelectric effect of diamond.** W. A. WOOSTER. *Mineralog. Mag.* 22, 65-9(1929).—This investigation employed 2 diamonds flattened parallel to an octahedron face and a force of 300 g. derived from magnetic attraction. The results show that the effect, if any, is within the limit of error of the expt. and less than  $1/200$  part of that of quartz cut perpendicular to an elec. axis. W. F. HUNT

**The so-called "thermokalite" and the existence of sodium bicarbonate as a mineral.** F. A. BANNISTER. *Mineralog. Mag.* 22, 53-64(1929).—Saline incrustations collected 40 years ago about 9 miles west of Naples and provisionally labelled "thermokalite" have been shown by recent investigations to consist of a mixt. of trona, thermohalite, thenardite and free  $NaHCO_3$ . No K salts are present. The  $NaHCO_3$  constitutes over 20% of the mass and the name *nahcolite* ( $NaHCO_3$ -lite) is suggested for it. W. F. HUNT

**The structure of boracite.** JOHN W. GRUNER. *Am. J. Sci.* 17, 453-60(1929); cf. *C. A.* 23, 795.—Data from oscilation spectrograms show that the unit cell of boracite

is base-centered orthorhombic with  $a_0 = b_0 = 16.97$  A. U. and  $c_0 = 12.00$  A. U. for colorless crystals. The unit cell contains 8 mols. of  $Mg_2Cl_2B_{14}O_{28}$ . The space group is probably  $C_{2v}^{11}$ , although  $C_{2v}^{12}$  could not be eliminated with certainty. R. J. H.

**Ben Nevis, Munro, Kamiskotia and other base-metal areas, Districts of Cochrane and Timiskaming.** T. L. GLEDHILL. *Rept. Ontario Dept. Mines* 37, Pt. 3, 1-52 (1928).—Sulfide replacement ores carrying Cu, Au, Ag and Zn were noted, similar to those in Quebec. Rocks and geological structures were also found to be alike. An ore-body of fairly good size has already been proved on Hollinger claims in Kamiskotia; additional finds of Cu, Pb and Zn are to be expected. E. I. S.

**Primary platinum deposits.** A. ZAVARITSKII. *Mining Ind. Mag. S. Africa* 7, 503-4, 547-50 (1929).—General geological conditions of platiniferous zone of Urals are outlined and the origin of the dunite complex is discussed. The dunite core is regarded as a product of solidification of liquid dunite magma, in the lower part of which Pt was localized. The distribution of Pt in the Nijni-Tagilsk dunite massive is discussed. The Pt is always associated with chromite; the types of Pt metals in the deposit are noted and a comparison of Russian and Transvaal deposits is made. E. I. S.

**Certain lead-zinc deposits in the district of Algama.** M. E. HURST. *Rept. Ontario Dept. Mines* 37, Pt. 3, 68-78 (1928).—A description of Vacheresse, Kirby-Legge, Victoria, Cascade and Kozak properties; while ore has not been developed on a com. scale, showings warrant further investigation. E. I. S.

**Lead-zinc ore deposits in the Save basin faults of Litiya type.** A. TORNUST. *Berg u. Huttenmann. Jahrb.* 77, No. 1, 1-27 (1929).—Detailed description of geology and mineralogy of Pb-Zn deposits in northwestern Yugoslavia. Genesis of the deposits and comparison with similar deposits in Eastern Alps are discussed. E. I. S.

**The Manitoba tin discoveries.** R. C. ROWE. *Can. Mining J.* 50, 284-5 (1929).—Brief account of tin ore occurrence at Shatford Lake and later discovery at Bernice Lake. Cassiterite is distributed irregularly in feldspathic pegmatite dikes; commercial ore-body is not proven. E. I. S.

**The bauxite deposits of the Rhone Delta.** V. CHARRIN. *Génie civil* 94, 258-60 (1929).—Maps and description of geological features. E. I. S.

**Government potash exploration in Texas and New Mexico.** G. R. MANSFIELD AND W. B. LANG. *Am. Inst. Mining Met. Eng., Tech. Pub.* No. 212, 17 pp. (1929).—A preliminary account of work done by the U. S. Geological Survey and Bur. of Mines. The Permian salt basin, salt accumulation therein, conditions affecting selection of drilling sites, N. Mex. and Tex. core tests and private exploration stimulated by government and state activity are discussed. The principal economic data relating to the 10 test wells are tabulated and indicate that at least 2 have beds of polyhalite sufficiently rich and thick to suggest com. exploitation, and 2 others offer com. possibilities. W. H. BOYNTON

**The salt deposits of the northeast bench of the Mansfelder basin found on opening the Wils, Johannashall and Salzünde potash mines.** ERICH MÜLLER. *Kali* 23, 57-9, 74-6, 89-92, 102-9 (1929).—Salts corresponding to the order of deposit of the Stassfurt profile are not found here in their primary, petrographic formation, but are almost wholly recrystd. as they were covered in the Mesozoic era, heated and altered chemically. They could not have sepd. from normal sea water. The original solns. must have had high concns., since the present geological profile of the K deposits does not correspond to the van't Hoff and Jänecke law of mass action. The Ca salts have sepd. mainly as anhydrite and not as gypsum. The Everding, Naumann, Rózsza and Seidl theories of rock salt formation must be abandoned from petrographic findings of a geological and physico-chem. standpoint. E. M. SYMMES

**The relation of chemical composition to texture of groundmass in siliceous lavas.** HOWARD A. POWERS. *J. Geol.* 37, 268-71 (1929).—Siliceous lavas show 2 types of groundmass textures, either rhyolitic with spherulitic, granophyric, or microgranulitic assemblages of quartz and feldspar, or felted masses of tabular crystals characteristic of trachytes. A study of 50 siliceous lavas showed that rocks with more than 26% of quartz in the norm showed rhyolitic, those with less, trachytic texture. W. F. H.

**A composite stock at Snowbank Lake in northeastern Minnesota.** C. W. SANDERS, JR. *J. Geol.* 37, 135-49 (1929).—The composite stock is made up of 3 syenite masses differing slightly in age, intruded by granite. The differentiation is not due to assimilation or to desilication of digested limestone but to gravitative differentiation in the magmatic reservoir. The basic border phases approach the compn. of the early magma. W. F. HUNT

**The mode of origin of a reaction porphyry dike at Cornucopia, Oregon.** G. E. GOODSPED. *J. Geol.* 37, 158-76 (1929).—A stock of quartz diorite intruded a felds-

pathic schist forming a breccia. The foreign fragments reacted with the magma producing plagioclase of labradorite compn. with a sodic rim. Other changes in the siliceous magma involve biotite replaced by hornblende. The syntectic magma produced through chem. reactions was drawn off into a fissure-like mass forming a "reaction porphyry." W. F. HUNT

The stock of alkaline rocks near Libby, Montana. ESPER S. LARSEN AND J. T. PARDEE. *J. Geol.* 37, 97-112(1929).—The stock is composed largely of pyroxenite rich in apatite, which was the earliest of the intrusive bodies. Magnetite, garnet and biotite are also present. Locally, the rock is nearly pure biotite, now altered to vermiculite. The pyroxenite was followed by syenite and nephelite syenite. These in turn were followed by small dikes of granite. Hydrothermal action has altered the pyroxenite to fibrous hornblende, the nephelite to muscovite, zeolites, or albite, and has introduced considerable aegirite and titanite. Analyses are recorded for pyroxenite, biotite and nephelite syenite. W. F. HUNT

The tholeiite dikes of the north of England. A. HOLMES AND H. F. HARWOOD. *Mineralog. Mag.* 22, 1-52(1929); cf. *C. A.* 23, 66.—A study of certain intrusive rocks composed of basic plagioclase, pyroxenes, titaniferous magnetite and olivine with interstitial glass. Five major types are described with anorthite-bearing varieties of each. Chem. and mineral analyses are given and it is concluded that the different types of tholeiites cannot be explained on the basis of differentiation by crystn. and sepn. of the residual liquid. W. F. HUNT

Altered tuffs in the Ordovician in Minnesota. VICTOR T. ALLEN. *J. Geol.* 37, 239-48(1929).—A soft gray shale 3 in. thick interbedded with limestone near the base of the Decorah represents an altered tuff. It consists of montmorillonite retaining the structure of pumice. Other minerals include sanidine, quartz, biotite, apatite and zircon. It resembles the Ordovician bentonite of Kentucky and Tenn. with which it has been correlated. W. F. HUNT

Two [mineralogical] notes from Bohuslän. IVAR D. WALLERUS. *Geol. Fören. Förh.* 51, 100-4(1929).—(1) Blocks of limestone found at Tärnskar are different from all other limestones found in Scandinavia but similar to those found around the Mediterranean. It is supposed that they were used as ballast in some early Roman ship which was shipwrecked here. (2) A reddish boulder found at Styrsö turns out to be meteoric. W. SEGERBLÖM

A comparative study of different types of thermal stratification in lakes and their influence on the formation of marl. F. M. KINDLE. *J. Geol.* 37, 150-7(1929).—The relatively low temp. of the upper zone in the Great Lakes and in high mountain lakes (above 5000 ft. in southern Canada) prevents the development of the thin zone of warm water nearly satd. with  $\text{CaCO}_3$ , which is essential to marl deposition. W. F. HUNT

The first rains and their geological significance. ASSAR HADDING. *Geol. Fören. Förh.* 51, 19-29(1929).—A survey of the problems connected with the first condensation of water on the earth shows that these are astronomical, geophysical, geochemical, geological and biological. The influence of water on erosion, on the chem. sorting of material, on cementation and on the formation of sedimentary rocks shows that the first condensation of atm. water marks the boundary between 2 important periods of the earth's history,—the pre-aquatic time and the historic time. Conclusion: The leptite formation contains the oldest sediments of the earth, formed in connection with the first condensation of water. W. SEGERBLÖM

## 9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST AND R. H. ABORN

Progress and investigations in the preparation and working of metals in 1928. E. FISCHER. *Metallbörse* 19, 426-7(1929).—A review. W. C. EBAUGH

X-ray spectrography in metallurgy. J. LAISSUS. *Tech. moderne* 21, 161-5, 197-203 (1929).—A review. P. THOMASSET

**Principle, organization and results obtained in the working of a plant for the separation and concentration of ores by flotation.** CH. BERTHELOT. *Chimie & industrie Special No.*, 190-204 (Feb., 1929).—A general discussion. A. PAPINEAU-COUTURE

**Selective flotation plant of Potosi Industrial Co.** J. HORCASITAS. *Bol. minero* (Mexico) 27, 27-33 (1929).—The ore treated is chiefly from Potosi mine with 300 g. Ag per ton and 9.2% each of Pb and Zn. The plant and treatment are described and analyses of concentrates produced are given. E. I. S.

**Working low-grade copper ores by leaching or flotation.** FRIEDR. VOGEL. *Metall-horse* 19, 537-8, 705-6 (1929).—A survey of the present state of the art of Cu extn. from low-grade ores, with data from 11 well-known mining districts. W. C. EBAUGH

**Gravity concentration of Alabama öolitic iron ores.** F. D. DE VANEY, B. W. GANDRUD AND W. H. COGHILL. *Bur. Mines, Repts. of Investigations No. 2937*, 7 pp. (1929).—Employing gravity concn. to the öolitic ores results in the removal of siliceous gang, leaving the hematite as rich high-grade "slime" and as clean granular grains. The "slime concentrate" is recovered by desliming processes, and the öolitic grains and granular hematite are recovered by tables. A rubber-covered rod is used in an ordinary rod mill and acts as a sheller, which liberates the Fe and leaves the öolitic quartz grains unbroken. The öolitic grains are polished by the rubber-covered rods and are rejected by tabling. Tabling recovers the clean hematite, which is too coarse to overflow the desliming devices. A flowsheet is shown for the closed-circuit performance. Lab. results indicate that operating costs for 2000 tons per day should not exceed 40¢ per ton (909 kg.) milled. This figure includes dry crushing, dewatering, filtering the concentrate and disposing of the tailing; it is cheaper than magnetic log washing. The grade of concentrate is nearly as good but the recovery is not as high as in the magnetic process. A typical unit or section consisting of a rod mill, a drag deslimer, a 10-spigot classifier and 10 tables, would take 12 tons (10,909 kg.) per hr. of mill feed, yielding 8.7 tons of concentrate contg. 47.6% Fe, 14.2% SiO<sub>2</sub> and 5.5% CaO. The results were successful on four of five ores examd., the failure being on a slate-bearing ore.

W. H. BOYNTON

**Factors governing the entry of solutions into ores during leaching.** JOHN D. SULLIVAN, WALTER E. KECK AND GEORGE L. OLDRIGHT. *Bur. Mines, Tech. Paper 441*, 38 pp. (1929).—Expts. indicate that surface tension is not the governing factor. Although the surface tension has been lowered to  $\frac{1}{3}$  the value for water with Na oleate, the rate of penetration was practically unchanged. Poiseuille's law is also not the governing factor. The soly. of the gas within the rocks in the penetration liquid is the factor that detcs. the rate of ingress of solns. When air was displaced by SO<sub>2</sub>, 95% of the total penetration took place in 4 to 9 hrs., whereas it took distd. water approx. 60 hrs. to attain the same % penetration when voids of the same size and kind were filled with O. It took 120 hrs. for 5% CuSO<sub>4</sub> soln. to penetrate voids filled with air. The time needed increases with the size of the particle. This suggests the possible advisability of finer crushing of the ore before it is put on the heaps or of blasting directly to the desired size. The interest on the money from the extra Cu extd. in the shortened time would amply pay crushing or blasting costs. If waste gases are allowed to enter heaps and to displace the air before water is added, the solns. should penetrate more rapidly. Such gases would also help dissolve the Cu minerals present. H. C. P.

**Beneficiation of oxidized manganese ores by magnetic separation of roasted jig concentrates.** F. D. DE VANEY AND W. H. COGHILL. *Bur. Mines, Repts. of Investigations No. 2936*, 4 pp. (1929).—Tests on a variety of Mn-Fe ores show that some of them are amenable to magnetic sepn. after a short roast. The P and insol. are locked more with the Fe than with the Mn. The results of roasting and magnetic sepn. of a Tennessee concentrate, a Georgia concentrate and a Virginia concentrate are tabulated. When the impurities of some of the oxides of Mn are carried as a phys. mixt. with Fe-oxide grains, a reducing roast will magnetize the Fe oxide, permitting removal by a low-intensity magnet and leaving a clean concentrate of Mn ore. Thus, some ore contg. too much Fe to make ferromanganese may be brought to the ferrograde. W. H. BOYNTON

**Utilization of burnt pyrites as an iron ore.** C. FICALI. *Giorn. chim. ind. applicata* 10, 511-21 (1928); cf. C. A. 23, 359.—A description is given of the plant and method used by the Montecatini Co. at Porto Maghera, where burnt pyrites is used for the prepn. of about 400 tons per day of agglomerated ore, mostly utilized by the Fe industry. The agglomeration of finely divided Fe ore, in particular of burnt pyrites, by the briquetting process consists in heating the material, previously compressed into blocks, to about 1350°. The various hypotheses advanced in explanation of the changes taking place, viz. (1) formation of silicates in the fused and solid states, (2) semi-fusion (sintering) of the Fe oxides and (3) recrystn. of these oxides, are examd. Hypothesis

(1) is excluded as a result of microscopical examn. and in virtue of the possibility of agglomerating pure  $\text{Fe}_2\text{O}_3$ , and (2) by reason of the difference between the m. p. of the oxides (about  $1550^\circ$ ) and the actual temp. of agglomeration, which in certain circumstances can be effected even at about  $1200^\circ$ . The exptl. results favor hypothesis (3), and it appears that the red, earthy hematite contained in the burnt pyrites is transformed by the heating into a black, cryst.  $\text{Fe}_3\text{O}_4$ , magnetite being formed as an intermediate product possessing catalytic properties. B. C. A.

**Precipitation of lead and copper from solution on sponge iron.** G. L. OLDRIGHT, H. E. KEYES, VIRGIL MILLER AND W. A. SLOAN. *Bur. Mines, Bull.* 281, 128 pp. (1929).—Vigorously stirred solns. should be heated to  $60^\circ$  to ppt. the Pb in less than 1 hr. If stirred too vigorously particles of sponge Fe more thickly coated with Pb were observed to "ball." Freedom from "balling" was insured by slowly rabbling sponge Fe downward over a series of superimposed trays in a cylindrical tank and by allowing the pregnant soln. to flow upward countercurrently against the passage of the Fe. Products contg. over 80% Pb were made; the liquors running from the machine were barren of lth. To ppt. Cu an excess of 7.5% metallic Fe over the chem. equiv. was usually sufficient. Whether sponge Fe was added in stages or all at the start made little difference. The temp. increased very rapidly as the Cu was pptd. and was difficult to control. Often over 80% of the metal was replaced in 2 to 4 mins. An increase in acidity decreased the rate of Cu pptn. in the richer Cu solns. but increased it in the poorer solns. with 7.5% excess Fe. Where the resoln. of the Cu on account of the admission of air was not serious, the metal could be pptd. almost completely in 15 to 25 mins. with 7.5% excess sponge Fe. H. C. PARISH

**Solution of various oxidized copper minerals.** JOHN D. SULLIVAN. *Bur. Mines, Repts. of Investigations* No. 2934, 9 pp. (1929).—Approx. 100% of Cu in Cu-Azurite, Malachite, Chrysocolla and Tenorite is sol. in  $\text{H}_2\text{SO}_4$  or in acidified  $\text{Fe}_2(\text{SO}_4)_3$  solns. In 1 or 2% neutral  $\text{Fe}_2(\text{SO}_4)_3$  the soln. is slower, but in nearly every instance the minerals are completely decompd. in 24 hrs. or less. Soly. in 5% neutral  $\text{Fe}_2(\text{SO}_4)_3$  is about the same as that in  $\text{H}_2\text{SO}_4$  or in acidified  $\text{Fe}_2(\text{SO}_4)_3$ . Chrysocolla is often said to be insol in  $\text{H}_2\text{SO}_4$  or in ferric Fe solns. Such insol. silicates of Cu are probably Diopbase. H. C. PARISH

**Develops rapid method for determining clay in foundry sands.** H. L. CAMPBELL. *Foundry* 57, 412-3 (1929).—The material designated as clay consists of those particles which remain in suspension in water and which may be washed from the sand. The tentative method of the Am. Foundrymen's Assoc. for grading sands according to their clay content is long and tedious. The proposed rapid method: 100 g. of dry sand and 50 cc. of 1% NaOH soln. are placed in a 2000 cc. washing flask and the flask is clamped in the app., which is mounted on a wooden stand. The steel frame mounted on this base may be tilted and clamped in any position and to it are attached a small motor and a speed reducer. A cast-Al bolt is bolted fast to the slow-motion shaft of the speed reducer. The alkali deflocculates the clay from the grains and throws it into colloidal suspension, thus facilitating the washing. Details of the app. are shown in plan and elevation, and the complete mounted app. is illustrated. The sand grains are ground by the rotation of the washing flask for 5 mins. Washing is continued until the wash water in the sand trap is clear. W. H. BOYNTON

**Technology of the platinum metals.** OTTO FREUSSNER. *Metallwirtschaft* 7, 469-70 (1928).—The Pt group, including Pd, Rh, Ru, Ir, Os, is discussed as to chem. properties, m. ps., phys. properties and mech. characteristics. The sepn. of each element from the others is discussed, as well as a no. of the alloys of Pt. C. L. MANTELL

**Cadmium in 1927.** PAUL M. TYLER. *Bur. Mines, Mineral Resources of the U. S.* 1927, Part I, 323-39 (preprint No. 14 published March, 1929). E. H.

**Melting aluminum.** J. BALLY. *Rev. Aluminium* 4, 442-7 (1927); *J. Inst. Metals* 39, 661.—It is shown that about 70 kw. hr. of energy should, under good conditions, be required to melt 100 kg. of Al. Figures for the fuel consumption and melting costs are given for 4 types of furnaces: the reverberatory, heavy oil-fired reverberatory, coke-fired pot furnace, and producer-gas-fired pot furnace. A note is added on the use of elec. furnaces. H. L. D.

**Sorting red metal turnings and waste.** EDMUND R. THEWS. *Metallbörse* 19, 593-4 (1929).—The kinds of metal scrap to be expected from various industries and their behavior upon melting and refining are discussed. W. C. EBAUGH

**Chloridizing and cyanidation plant of Penyoles Mining Company, Achotla Unit, at Temixco, Guerrero.** C. BRUCHOLD. *Bol. Minero (Mexico)* 27, 34-9 (1929).—Ore from Suriana mines, with Au and Ag values, high in Fe, and with minor amts. of Pb, Cu and Zn is used. E. I. S.

**The theory and application of regenerative principles in the steel industry.** T. J. McLOUGHLIN. *Am. Iron and Steel Inst.*, Adv. Paper, 1929, 30 pp.—A discussion of fuel, thickness of brick and area of openings, effect of increased checker depth and efficiency of regenerators, distribution of waste gases and air, dust deposits, regeneration in blast-furnace stoves and application to soaking pits and reheating furnaces. Also in *Blast Furnace & Steel Plant* 17, 852-6(1929). E. I. S.

**The efficiency of hot-blast stoves.** J. B. FORTUNE. *Proc. Inst. Mech. Eng.* (London) 1928, 1021-32.—Tests were made on a 350-ton blast furnace equipped with 5 Cowper hot-blast stoves 90 ft. high and 21 ft. in diam., a total heating surface of 77,750 sq. ft. The gas supplied to stoves was cleaned by a Halberg-Beth dry-cleaning plant. The correct proportioning of gas and air was detd. by elec. CO<sub>2</sub> app. installed to det. CO<sub>2</sub> in the chimney of each stove. The efficiency of the stove was 79.12%. The total gas made by the blast furnace was 2,257,500 cu. ft. per hr. The total gas used at the stoves was 563,000 cu. ft. per hr. The proportion of gas used in heating blast was 25%. A. W. HOLMES

**The design and operation of the cupola.** A. S. BEECH. *Foundry Trade J.* 40, 355-6, 379-80(1929). E. H.

**Blast-furnace stock column.** S. P. KINNEY. *Bur. Mines, Tech. Paper No. 442*, 148 pp.(1929).—A study of the operation of a 700-ton blast furnace, attempting to follow the steps in reduction of the charge during the descent in the furnace shaft. Methods have been developed for the measurement of velocities of gas, temps., pressures and compn. of gas across a series of planes at any elevation between the inwall and center of the furnace. There are many illustrations, tables, curves, etc. An appendix covers: calibration of Pitot tube, the flow of air through beds of broken solids, and detn. of free area available for flow of air, and accuracy of calibration and conclusions thereon. W. H. BOYNTON

**An open-flame stationary hearth-type furnace for melting aluminum and its alloys.** R. J. ANDERSON, G. E. HUGHES AND M. B. ANDERSON. *Foundry Trade J.* 40, 357-8(1929).—See C. A. 23, 2141. E. H.

**Recording the results of metallographic investigations.** H. REININGER. *Metallography* 19, 145-7(1929).—All metallographic records are entered in a journal in chronological order and given current numbers: exptl. data are appended. Card index records are then made, the photographs filed on them, and classified into 10 types of alloys. W. C. EBAUGH

**The affinity of sulfur for metals.** C. FRICK. *Chem.-Ztg.* 53, 317-8(1929).—A comparison of the "affinity series" of metals for S, as detd. by Fournet (1834), Markus, Schweder, Thomsen-Durre, Ostwald, Guertier and Frick (1927). Very general agreement in results is observed in spite of the differences in methods of measurement used. W. C. EBAUGH

**Regularities in the structure of alloys.** A. WESTGREN AND G. PHRAGMÉN. *Metallwirtschaft* 7, 700-3(1928).—A crit. review of previously published data. R. F. M.

**Special properties of eutectics and eutectoid alloys in binary metallic systems.** P. SALDAU. *J. Inst. Metals*, Adv. Copy, No. 487, 21 pp.(1929).—The straight-line relationship (phys. properties plotted against compn.) characteristic of a mixt. of 2 different phases does not hold true with the eutectic or eutectoid alloys, even after annealing. The eutectic alloys in the systems Sn-Pb, Pb-Sb, Sn-Zn, Au-Zn and Au-Cd as well as Fe-C eutectoid alloys were investigated. It is also pointed out that for coalescence to occur in eutectic alloys an excess of one phase is necessary. J. W. B.

**Study of the internal cooling of homogeneous isotropic bodies.** J. MERCIER AND P. MICHOULTIER. *Rev. métal.* 26, 171-92(1929).—A study of the rate of cooling of heavy parts. Its importance, particularly as regards quenching, is brought out. The article is very largely mathematical, and from the results numerous curves and 3-dimension surfaces are plotted. The value of the results obtained is discussed from the standpoint of their application in exptl. work and industrial practice showing, e. g., how the internal structure of heavy parts after quenching can be predetd. by means of the graphs which are given. A. PAPINEAU-COUTURE

**Magnetic susceptibility of some amalgams and binary alloys.** W. G. DAVIES AND E. S. KEEPING. *Phil. Mag.* [7], 7, 145-53(1929).—The relative magnetic susceptibilities of dil. amalgams of Au, Sn, In and Ga with respect to that of Hg were detd. by means of a Curie-Chineveau magnetic balance. The (diamagnetic) susceptibility decreases in abs. value but not linearly as the concn. of the dissolved metal increases. Indium produces a greater effect on the susceptibility of Hg than the other elements tried. The susceptibilities of Cu-Mg and Cu-Sb alloys over a wide range of compn. were detd. The susceptibility-compn. curves for Cu-Mg show maxima corresponding to eutectics

on the ordinary equil. diagram and minima corresponding to the compds.  $\text{CuMg}_2$  and  $\text{Cu}_2\text{Mg}$ . Annealing increased the susceptibility. L. H. REYERSON

The influence of the dimensions of the test pieces on the determination of the yield point of metallurgical products. J. COURNOT. *Compt. rend.* 188, 995-7 (1929).—Al and duralumin wires 1 to 2.8 mm. in diam. were tested at 15° to 350°. Increase in diam. had a like effect on the yield point. A. C. HIGGINS

The relation between stress and strain in the impact test. RYŌNOSUKÉ YAMADA. *Science Repts. Tohoku Imp. Univ.*, 1st Series, 17, 1179-1211 (1928).—Stress-strain curves were obtained for 0.1, 0.3 and 0.5% C steels, and a Ni-Cr steel contg. 3.5% Ni and 0.8% Cr, with a Charpy impact tester by the method of Körber and Storp. The low-temp. brittleness of steel was investigated and in general it was found that the temp. at which steels become brittle is higher in impact than in static tests. DOWNS SCHAAP

Work-softening and a theory of intercrystalline cohesion. F. HARGREAVES AND R. J. HILLS. *J. Inst. Metals*, Adv. Copy, No. 488, 27 pp. (1929); cf. C. A. 22, 3870.—Further work on work-softening established the following conditions necessary for its occurrence: (1) the presence of more than one phase, not necessarily a eutectic; (2) both constituents must have the property of undergoing spontaneous annealing after working at air temp. A theory of intercryst. cohesion is outlined, which states the existence of a transition zone between 2 orientations. This is not to be regarded as amorphous metal, for, given the same 2 orientations and the same relative position of the boundary, the same pattern of at. arrangement is always found in the unstressed metal. The cause of the very pronounced softening by heavy working is attributed to interphase boundary action and to the retention of the individual phases in a quasi-viscous condition. Fatigue of metals, cause of creep and season cracking are briefly discussed Also in *Engineering* 127, 767-71 (1929). J. W. BOECK

The erosion of guns. R. H. GREAVES, H. H. ABRAM AND S. H. REES. *J. Iron & Steel Inst.*, Adv. Copy, No. 4, May, 1929, 55 pp.—From the results of erosion vent expts. showing the relative corrodibilities of different steels and non-ferrous metals, and the examn. of many worn guns, it is concluded that the erosion occurring in large guns is almost wholly due to the melting and sweeping away of metal from the bore surface by the rapid stream of highly heated propellant gases. The only practicable means of reducing erosion is by use of cooler propellants and a careful design of the chamber. DOWNS SCHAAP

Instructions for the examination and selection of bare electrode (welding) wire. J. FUCHS. *Electrotech. Maschinenbau* 46, 527-34; *Science Abstracts* 31B, 421 (1928).—A bare electrode wire to give best service should analyze approx.: C less than 0.1%, Si trace, Mn 0.5%, S less than 0.03%, P less than 0.04%. M. McMAHON

The annealing of cast iron. H. H. BEENY. *Foundry Trade J.* 40, 229-31, 251-3 (1929).—Ordinary foundry Fe contg. 2.19% Si can lose 0.2% combined C when heated 200 hrs. at 300°. This loss increases with increasing total C and Si. 1% Si-Fe retains most of the combined C even after prolonged annealing at 550°. In irons contg. 1.00 to 1.30% a slight reduction in combined C occurs at 650° but the loss increases rapidly up to 750° where it reaches its max. Strength falls off with loss in combined C. Striking increases in strength with annealed chill-cast bars were obtained when the compn. was such that deep chill formation was avoided. This makes for soundness and the interior metal possesses a much finer form of graphite than that obtained by annealing completely white metal. H. C. PARISH

Nickel-chrome alloy iron. W. R. SHIMER. *Foundry Trade J.* 40, 254 (1929).—The introduction of an alloy-bearing pig Fe to the cupola is more effective than the addn. of alloys synthetically. The benefits attending the use of Ni-Cr pig Fe may possibly not be obtained from Ni and Cr alone, but also from other deoxidizers in the Fe such as high C, Ti and a slight quantity of V. The addn. of even 4% of Ni-Cr pig Fe raises the hardness from 180 Brinell to 200-220 and increases machinability. Ni strengthens cast Fe and aids in sepg. graphite. Cr holds C in combined form. As Cr predominates in Mayari pig Fe its use means an increase in combined C and a stronger Fe. For heavy heat-resisting castings with Si from 1 to 2%, 25% of Ni-Cr pig Fe is added to cupola mix. It reduces shrinkage, makes a sounder, cleaner and close-grained casting. H. C. PARISH

Effect of nitrogen in iron and steel. V. N. SVECHNIKOV. *Heat Treating and Forging* 15, 436-41 (1929).—The effects of N content on the phys. properties of iron and steel and the sources of N are reviewed. E. H.

Third report on heterogeneity of steel ingots. A COMMITTEE OF THE IRON AND STEEL INST. *J. Iron & Steel Inst.*, Adv. Copy, No. 1, May, 1929, 71 pp.—The report describes the progress made in 4 investigations devoted to researches into fundamental

matters. Andrew and Binnie describe their exptl. methods of detg. the liquidus and solidus ranges of some com. steels and the application of the data obtained to the problem of ingot manuf. They also report the results of their work on detg. the soly. of Fe and Mn sulfides in steel by the thermal method. Desch and Smith describe their app. and methods, and give the data so far obtained in their expts. to det. the changes in density occurring in steel in the neighborhood of the f. p. A mathematical analysis of the effect of latent heat on the solidification of steel ingots is made by N. M. H. Lightfoot.

Standard specifications for carbon-steel car and tender axles. Serial designation A 21-7. Bur. of Foreign and Domestic Commerce, *Industrial Standards No. 14*, 14 pp. English-Spanish ed. Text as adopted by the Am. Soc. for Testing Materials. Revised, 1927.

E. J. C.

Standard specifications for carbon-steel forgings for locomotives. Serial designation A 20-8. Bur. of Foreign and Domestic Commerce, *Industrial Standards No. 13*, 16 pp. Text as adopted by Am. Soc. for Testing Materials. Revised, 1928. E. J. C.

Relation between various degrees of hardness of unhardened carbon steel. A. WALLICH AND H. SCHALLBROCH. *Maschinenbau* 8, 69-74(1929).—Steel contg. from 0.1 to 1.0% of C was exposed to various hardening tests, as a result of which a curve is plotted showing ratio of Brinell hardness to new hardness coeff.; corresponding equations are derived. Bibliography.

E. I. S.

Aging and recrystallization tests on boiler plate. A. POMP. *Z. Bayer. Revisions-Ver.* 33, 7-9, 26-7, 93-6(1929).—Aging is accelerated by annealing of cold-worked steel. The aging tendencies of different steels vary greatly. Results are given of strength and notched-bar tests to det. the conditions governing both natural and artificial aging and to obtain information on the relation of temp. to notch resistance of aged material. Fourteen different steels, 10 without alloy, and 4 with Ni addns. were tested.

E. I. S.

The mechanical and metallurgical properties of spring steels as revealed by laboratory tests. G. A. HANKINS AND MISS G. W. FORD. *J. Iron & Steel Inst.*, Adv. Copy, No. 5, May, 1929, 28 pp.—Brinell, tensile, fatigue, Izod and torsion tests were made on hardened and tempered low-Cr steel, high-Cr steel, Ni-Cr steel, and 2 water-quenched C steels contg. 0.60 and 0.46% C, resp.

DOWNES SCHAAF

Brittleness in mild steel. G. R. BOLSOVER. *J. Iron & Steel Inst.*, Adv. Copy, No. 3, May, 1929, 15 pp.—Detailed results are reported of an investigation into the cause of the brittleness in mild steel when deformed beyond certain limits and reheated to approx 250°. B. suggests that an internal strained condition is set up in mild steel with resulting brittleness because a sub-microscopic recrystn. takes place along the planes of max. movement when the cold-worked material is heated to 250° without recrystn. of the mass of metal.

DOWNES SCHAAF

The differential method for measuring the thickness of hard cases without sectioning them. EDWARD G. HERBERT AND PAUL WHITAKER. *J. Iron & Steel Inst.*, Adv. Copy, No. 6, May, 1929, 10 pp.; *Engineering* 127, 593-4(1929).—A method for measuring the thickness of the case on case-hardened steels consists in making 2 different hardness tests, a primary test (Herbert pendulum), which measures only 1 variable, the hardness of the case, and a secondary test (Brinell), which measures the combined effects of 2 variables, hardness and thickness of the case, the difference between the 2 hardness values being a function of the thickness of the case. The general procedure for the inspection of case-hardened work by means of the cloudburst method is given in detail.

Utilization of mineral oils for the thermal treatments of steels. L. ROY. *Aciers spéciaux* 4, 75-7(1929).—The properties of different petroleum oils are presented.

A. J. MONACK

Influence of addition elements on the properties of steels. (Carbon.) L. PERSOZ. *Aciers spéciaux* 4, 69-74(1929); cf. C. A. 23, 2139.—The Fe-C equil. diagram is explained and discussed. Photomicrographs show the various compds. and eutectics formed in different steels. A graph shows the resistance to rupture and the resilience for C steels as functions of the temp. of reheating after tempering. The effects of C on other properties are discussed.

A. J. MONACK

Chromargan, a non-oxidizing steel. W. SACK. *Z. ges. Giessereipraxis* 50, No. 8, 29-30(1929).—This alloy steel (made by Krupp) is used for turbine blades, shafts, valves, cutlery and table ware, medical instruments, etc. It is classified in 2 groups, VM and VA; the former has av. Cr content of 13 to 15% and small Ni content; the latter has 18 to 25% Cr content. VM is magnetic and VA non-magnetic.

E. I. S.

Chromiumplating steel before heat treating. S. TOUR. *Rochester Eng.* 7, 198-201

(1929).—Cr plating gives promise of suitable protective layers that can be put on steel directly to protect it from oxidation, carburization, or decarburization during heat-treatment process.

E. I. S.

**Electrical properties of nickel-iron alloys.** G. J. SIZOO AND C. ZWICKER. *Z. Metallkunde* 21, 125-6(1929).—By sucking molten alloys of Fe (99.9%) and Ni (99.6%) into a quartz tube of 1 mm. diam., S. and Z. succeeded in obtaining rods of about 20 cm. consisting of single crystals, which could be readily drawn into wires of 0.25 mm. diam. These wires were annealed *in vacuo* at 900° and their elec. resistance was detd. at 0° and 100°. The curve for the sp. elec. resistance shows a min. at 34% Ni and a flat max. around 68% Ni. The min. and max. are more pronounced in the curve for the temp. coeff. of the elec. resistance. The latter shows also a pronounced max. at 26% Ni and a min. at 88% Ni.

H. S. VAN KLOOSTER

**Properties of materials at high temperatures. V. The "Creep" strength of a "high-nickel high-chromium steel," between 600° and 800°.** H. J. TAPSELL AND J. REMFRY. Dept. Sci. Ind. Research. *Eng. Research, Special Rept.* No. 15(1928), cf. C. A. 22, 4433; 23, 77.—Material of the following compn. was used for expts. C 0.46, Si 1.20, Mn 1.09, Ni 26.5, Cr 14.0, W 3.59, S 0.028 and P 0.026%. Short-time tensile tests show an ultimate stress varying from 45.9 tons per sq. in. at 15° to 17.2 at 800°. The estd. value of limiting "Creep" stress at 600° is 11 tons per sq. in., at 700° 6 and at 800° 2 tons per sq. in.

H. C. PARISH

**Ferro-silicon.** K. TH. KÜRTEN. *Metallwirtschaft* 7, 911-4(1928).—A review of the history, production and properties of ferro-silicon, with especial emphasis on the chemistry of the reduction process.

ROBERT F. MEHL

**Sherardizing.** A. P. PETRIE. *Metal Ind.* (London) 34, 483-4(1929).—Review.

E. H.

**Development and application of Widia.** R. D. PROSSER. *Am. Mach.* 70, 587-9(1929).—A brief history of development of W carbide material and some practical considerations regarding its proper use in a shop.

E. I. S.

**The cast structure of copper.** P. SIEBE. *Metallwirtschaft* 8, 391-5(1929).—The type and temp. of the mold, the temp. of the metal when cast, and the degree of deoxidation of the metal in the refining process det. the cast structure of Cu.

C. H. LÖRIG

**The change in structure of copper during the refining process.** L. TRONSTAD. *Metallwirtschaft* 8, 396-7(1929).—The structure of solidified Cu is detd. chiefly by its Cu<sub>2</sub>O content.

C. H. LÖRIG

**Brittleness in arsenical copper. II.** CLEMENT BLAZEY. *J. Inst. Metals, Adv. Copy*, No. 486, 6 pp.(1929); *Metal Ind.* (London) 34, 291-3.—A type of brittleness in arsenical Cu described in a previous paper, characterized by low tensile strength and elongation and inability to withstand repeated bending after annealing below 600-650°, was found to be produced under certain conditions by small quantities of Bi. It occurs on low-temp. anneals only and is recurrent. After annealing at a high temp the brittleness disappears but reappears after cold working and again annealing at a low temp. P added after Bi, or remelting, destroys this susceptibility to brittleness. The effects of Sb, P, S and As were also investigated.

J. W. BOECK

**The effect of sulfur dioxide on bronze and copper.** P. RÖNTGEN AND G. SCHWIETZKE. *Z. Metallkunde* 21, 117-20(1929).—Whereas SO<sub>2</sub> causes porosity in Cu due to a reversal of the reaction: SO<sub>2</sub> + 6Cu = Cu<sub>2</sub>S + 2Cu<sub>2</sub>O on cooling, there is no gas porosity when SO<sub>2</sub> is added to a molten bath of bronze (10% Sn), since the reaction: SO<sub>2</sub> + 2Cu + Sn = Cu<sub>2</sub>S + SnO<sub>2</sub> is not reversible. R. and S. assume that Al-bronze, brass and Ni alloys contg. Zn behave like bronze. Porosity caused by SO<sub>2</sub> can be avoided by suitable deoxidation.

H. S. v. KLOOSTER

**X-ray investigation of aluminum at high temperatures.** A. I. ALICHANOV. *Z. Metallkunde* 21, 127(1929).—A. made an x-ray study of Al at temps. up to the m. p. in order to find out whether Al possesses a transition point between 575° and 600° as claimed by various authors. The specimen used was a wire of 0.5 mm. diam. and a length of 4 cm. through which a constant current was sent. The spectrograms gave the same system of lines at all temps. indicating a face-centered cubic arrangement with an av. lattice constant of 4.107 Å. U. = 0.005.

H. S. v. KLOOSTER

**Influence of sulfur on copper-lead alloys.** HIDEO NISHIMURA AND SHIRO ANDO. *Suiyokashiki* 5, 696-706(1928).—The authors found that the addn. of a small quantity of S can prevent the usual marked segregation in a 50:50 Cu-Pb alloy. Specimens contg. no S or 0.1 and 1.3% S show marked irregularity in the distribution of hardness, microscopic examn. also confirming the existence of marked segregation. The specimens contg. 0.4 and 0.8% S show little segregation. Impact test shows that the addn. of S makes the material brittle. From the results of thermal and other analyses they

conclude that when S is added, it is adsorbed on the primary crystals of Cu, preventing the growth of dendritic crystals of Cu, and preventing segregation. K. SOMEYA

**Phosphor-bronze for foundry work.** EIICHIRO ITAMI. *Suiyokashii* 5, 717-49 (1928).—Tensile strength, hardness, impact, compression, cold working, annealing and corrosion tests were made on phosphor-bronze ingots contg. Cu 95, Sn 4 and P 0.3%. Microscopic examn. of the annealed specimen showed that when the annealing is made at a low temp. a eutectic contg. the phosphide of Cu is present besides the  $\alpha$  solid soln., while in the sample annealed at a high temp. no eutectic makes its appearance. K. S.

**Silver, its alloys and their preparation.** I. A. A. LEROUX. *Metallwirtschaft* 7, 467-8(1928).—The properties, both phys. and chem., of pure Ag and its alloys are discussed. The Cu-Ag phase-rule diagrams are given, as well as the mech. properties and photomicrographs of various constituents of the phase-rule diagram. Methods of prepn. of the pure alloys are described. C. L. MANTELL

**White gold.** L. NOWACK. *Metallwirtschaft* 7, 465-6(1928).—The theoretical background of these alloys is discussed, including the phase-rule diagrams for the Au-Pt and the Au-Ni systems. The mech. properties, constitution, working and fabrication of the alloys are discussed in some detail. C. L. MANTELL

**Transcrystallization of aluminum.** E. SCHEIL. Forsch. Inst. der Verein. Stahlwerke, Dortmund. *Z. Metallkunde* 21, 121-4(1929).—S. studied the effect of casting temp., mold temp. and thickness of container wall on the development of columnar crystn. in Al castings. Casting at high temp. in a cold mold causes trans-crystn. to the very center. At lower casting temps. (700°) a more granular structure is developed. Heating to 1100° followed by cooling to 700° and casting at that temp. produces mostly a radial structure with some equiaxed grains in the center of the ingot. H. S. v. K.

**Technology of aluminum and its alloys.** H. RÖHRIG. *Metallwirtschaft* 7, 502-7 (1928).—A review of progress and a discussion of the properties of pure Al and some of its alloys, particularly those with Fe and Si. C. L. MANTELL

**Some investigation on the improvement of aluminum silicon alloys.** MARIE L. V. GAYLER. *Metallwirtschaft* 7, 861-4(1928).—Supercooling of Al-Si alloys has practically the same improving effect as the introduction of small quantities of Na to the alloy. The cooling curves for the Al-Si alloy when supercooled essentially coincide with the ordinary curves for Na-treated alloys. It is impossible to obtain different curves for Na-treated alloy melts when rapidly cooled. Conclusion: the addn. of Na causes crystn. in alloys at the temps. of supercooling for normal alloys and the no. of grains would probably be increased. B. E. ROETHLI

**Magnesium and its alloys.** R. CAZAUD. *Aciers spéciaux* 4, 83-8, 131-9(1929).—C. discusses the electrolytic metallurgy of Mg, phys. properties, Mg and corrosion, chem. properties, founding of Mg. A short bibliography is appended. The following are discussed by means of equil. diagrams and photomicrographs: Mg-Al, Mg-Cu, Mg-Zn, Mg-Cd, Mg-Pb, Mg-Ce, Mg-Ca and Mg-Si alloys. A. J. MONACK

**The importance of design and setting of large kettles used for refining low melting-point alloys.** HARRY C. LANCASTER. *J. Inst. Metals*, Adv. Copy, No. 485, 6 pp., 1929.—L. demonstrates that on increasing the size of the cast-Fe kettles from 20 to 50 tons capacity 2 factors which help to increase the life of the kettle are the shape of the kettle and the method of setting. J. W. BOECK

**The influence of pickling operations on the properties of steel.** H. SUTTON. *J. Iron & Steel Inst.*, Adv. Copy, No. 15, May, 1929, 24 pp.—Expts. were made to ascertain the influence of pickling mild steel, medium C steel and alloy steel in acid solns. The work affords addnl. evidence of the deleterious effect of H generated at the surface of steels during pickling operations. DOWNS SCHAAP

**The significance of organic sulfonic acids for chemical scale removal.** ORTO MERZ. *Arch. Wärmewirt.* 9, 394-5(1928).—The  $CH_3O$  condensation product of naphthalenesulfonic acid is recommended as an agent that requires no subsequent alkali wash and that attacks Fe much less than ordinary pickling agents. ERNEST W. THIELE

**Lanolin rust preventers.** C. JAKEMAN. Dept. Sci. Ind. Research, *Eng. Research, Special Rept.* No. 12, 22 pp. (1929).—Steel pieces coated with lanolin by immersion in or painting with solns. of lanolin (in benzene, xylene, white spirit solvent, naphtha, turpentine, tetralin,  $C_2H_2Cl_4$  and  $C_2HCl_3$ ) and exposed to weather were protected from 40 to 137 days (the benzene soln. being the best and tetralin the poorest). Introduction of paraffin or ceresin yielded a harder and more durable coating. Crude lanolins of low acidity were found best. Lanolin coatings were found superior to petroleum grease both in protective power and adhesion. B. E. ROETHLI

**The corrosion problem with particular reference to the prevention of corrosion by corrosion-resistant alloys.** WILHELM WIEDERHOLT. *Metallwirtschaft* 7, 856-61

(1928).—A review of the general methods of corrosion prevention with special reference to the use of alloys in which mixed-crystal formation takes place. The difference between "passive limit" and "resistant limit" is defined. "Passive limit" refers to the concn. of metal alloyed with another necessary to yield a material which is capable of forming a very dense resistant film when in the corroding medium. "Resistant limit" refers to the min. concn. of the nobler metal in the alloy which will cause the formation of a material which is more stable in the corroding medium due to energy considerations. Alloys of Au-Ag, Si-Al, Cu-Zn are discussed from this point of view.

B. E. ROETHLI

**Organic type inhibitors in the acid corrosion of iron.** J. C. WARNER. *Trans. Am. Electrochem. Soc.* 55 (preprint) 9 pp. (1929).—Further evidence is presented which substantiates the theory that inhibitors of the org. type function by increasing the over-voltage required for the deposition of H. The effect of various concns. of gelatin upon the energy required for the deposition of H on iron has been studied, and these results have been compared with the inhibitor action of gelatin in the acid corrosion of Fe. The effect of small-quantities of quinoline, aniline, bases from petroleum fractions, and bases from coal-tar oils, upon the energy required for the deposition of H has been studied, and the effectiveness of these substances as inhibitors in the acid corrosion of Fe has been detd. Expts. indicate that any substance, which will form a large positively-charged oily ion, or a positively-charged, oily, colloiddally-dispersed particle, in acid soln., should inhibit the acid corrosion of Fe if the substance cannot be electrolytically reduced.

C. G. F.

**Protection against corrosion.** OTTO TIEDEMANN. *Metallwirtschaft* 7, 285-9, 314-6 (1928).—A review.

B. E. ROETHLI

**Excessive corrosion of galvanized mild steel cisterns.** H. F. RICHARDS. *Iron and Steel Ind. and Brit. Foundryman* 1, 183-4 (1928).—Excessive corrosion of galvanized mild steel cisterns is attributed to the high CO<sub>2</sub> and NaCl content and increased temp., which liberates more CO<sub>2</sub>. Cf. C. A. 23, 1859.

B. E. ROETHLI

**Corrosion of iron and steel.** W. B. LEWIS AND G. S. IRVING. *Iron and Steel Ind. and Brit. Foundryman* 1, 185-6 (1928).—A discussion of the existing corrosion theories

B. E. ROETHLI

**Regarding several cases of corrosion in aluminum transmission cables.** H. BOHNER. *Z. Metallkunde* 20, 309-15 (1928).—An illustrated discussion of the effects of chem. compn., roll strains, strains and abrasions occurring in erecting lines, and changes in compn. and structure due to short circuits or lightning on corrosion

B. E. ROETHLI

**Corrosion of centrifugal pumps.** R. W. MÜLLER. *Korrosion u. Metallschutz* 5, 59-61 (1929).—Corrosion of rotors and casings of centrifugal pumps occurs mostly in the portions of pumps operating below atm. pressure. The corrosion is attributed to the liberation of O<sub>2</sub> at the metal surfaces. In series pumping systems practically all the corrosion occurs in the low-pressure stage. A bronze brine pump with cast-iron bolts failed by graphitic corrosion of the bolts due to electrolytic corrosion in which the bolts were anodic and the rotor and casing cathodic.

B. E. ROETHLI

**Tests on corrosion of aluminum and aluminum alloys.** W. SCHWINNING AND H. JAHN. *Korrosion u. Metallschutz* 5, 49-58 (1929).—Tests of Al and Al alloys by the thermic HCl test, oxidizing NaCl test and fatigue tests gave results which were not comparable among themselves and could therefore hardly be considered as means for estg. the length of life of the materials in question under actual service conditions.

B. E. ROETHLI

**The attack of metallic pipes by direct and by alternating currents.** W. BECK. *Z. angew. Chem.* 41, 1361-7 (1928).—A discussion showing the theoretical and practical aspects of corrosion by stray currents in a. c. and d. c. circuits. A. c. circuits are more dangerous to buried pipe than d. c. because of the 3 possible ways in which currents are caused to flow in pipe within reach of the stray currents: contact, induction and influence.

B. E. ROETHLI

**Regarding the ferroxy indicator.** WILHELM VAN WÜLLEN-SCHOLTEN. *Korrosion u. Metallschutz* 5, 62-4 (1929).—The ferroxy indicator in studying bare metal gives erroneous results when made up in agar-agar because of the fact that it does not show differential aeration effects. It is also stated that the concns. of K<sub>3</sub>Fe(CN)<sub>6</sub> and phenolphthalein are too high and that the metal is immersed in an unnatural electrolyte. S. finds that concns. of 0.004% phenolphthalein and 0.008% K<sub>3</sub>Fe(CN)<sub>6</sub> in a molal soln. of NaCl do not appreciably change the properties of the electrolyte and give results which are not in error.

B. E. ROETHLI

**The effect of cold-working on the corrosion of iron and steel.** HIKOZO ENDO. *Science Repts. Tohoku Imp. Univ.*, 1st Series, 17, 1265-78(1928); cf. C. A. 23, 806.—The wt. loss of steels contg. 0.1, 0.3, 0.5, 0.7, 1.1 and 1.3% C was detd. after they had been subjected to different kinds of mech. stress by immersing them in a 1%  $H_2SO_4$  soln. kept at 25° for 72 hrs.

**Causes and prevention of corrosion of aluminum and its alloys.** SCHULZ. *Metallwirtschaft* 7, 507-8(1928).—A review of the factors causing corrosion, with some emphasis on electrolytic corrosion.

**Much work on corrosion problems in progress in laboratories.** F. R. STALEY. *Oil & Gas J.* 27, No. 40, 66(1929).—Work on the resistance of alloys to corrosion is reviewed.

**The corrosion of aluminum.** JEAN CALVET. *Compt. rend.* 188, 1111-4(1929).—Al made by the Hoopes process, a high grade of Al made in France and an ordinary Al were tested for corrosion in various org. and inorg. acids and in sea salt. In every case the Hoopes-process Al showed the greatest resistance to corrosion and the ordinary Al, the least. This conforms with the electrochem. theory of corrosion.

**The mechanism of the calcium hydrate process (for protecting pipe).** MAX GROECK. *Gas u. Wasserfach* 72, 319-24(1929); Polemical (cf. Bücher and Schulte, C. A. 21, 1960).—An attack on the published theories as to the mechanism of the Bücher process for protecting pipe lines from corrosion by aggressive  $CO_2$ . Answer to Groeck by the CHEMICAL STAFF OF THE PREUSS. LANDESANSTALT FÜR WASSER-, BODEN- UND LUFTHYGIENE. *Ibid* 324-8.—Comments by CHR. BÜCHER. *Ibid* 328. R. W. R.

**Practical methods of oxy-acetylene welding.** L. A. COWLES. *Power Plant Eng.* 33, 482-3, 530-1(1929).—A general article. Some special suggestions are made for steel and wrought Fe, Cu and Al.

Periodic passivity of Cr and Cr alloys, and the influence of temperature on passivity potentials (STRAUSS, HINNÜBER) 2. **Roasting ores.** ELECTRO-METALLURGICAL ORE REDUCTION, LTD. Fr. 652,076, Apr. 2, 1928. Ores and metallurgical products to be roasted are mixed in a finely divided state with an aluminous binding agent such as clay, and a soln. of  $FeSO_4$ . The plastic mixt. is formed into rings or other shape to prevent close packing. Pyrites or other S compds. may be added if this is scient.

**Roasting and reducing ores, etc.** FREDERICK L. DUFFIELD. Fr. 652,627, April 12, 1928. In roasting and reducing metallic ores in a 2-stage treatment, 2 rotary furnaces are used alternatively for each stage of the treatment.

**Treating ores, etc.** STANLEY C. SMITH. Fr. 652,213, April 4, 1928. See Brit. 295,224 (C. A. 23, 2143).

**Separating ores from gang, etc.** I. G. FARBENIND. A.-G. Fr. 652,244, April 5, 1928. Solid substances of different d., particularly ores and gang, are sepd. by imparting to the ground-up solids a wave agitation by blowing gases through the whole layer.

**Apparatus for separating ore and gang by use of air currents.** I. G. FARBENIND. A.-G. Brit. 299,936, Aug. 20, 1927.

**Apparatus (with an inclined trough) for separating crushed ore constituents by aid**

of liquid currents and air. WILLIAM E. ENDREZZE. U. S. 1,714,007, May 21. Structural features.

**Iron ores.** GRANULAR IRON CO. Fr. 652,050, Mar. 31, 1928. Fe ores are reduced by mixing with a carbonaceous material contg. S and with lime, heating in a slightly inclined rotating furnace in a reducing atm. and at a temp. below the f. p. of Fe. Cf. C. A. 23, 590.

**Recovery of tin from solutions also containing arsenic.** HENRY HARRIS. U. S. 1,714,667, May 28. Calcareous material such as  $\text{Ca}(\text{OH})_2$  is added, as the pptg. agent for the Sn, to a soln. already contg. a  $\text{CO}_2$  compd. such as  $\text{Na}_2\text{CO}_3$  to prevent simultaneous pptn. of As. Cf. C. A. 22, 3023.

**Washing or leaching tin-bearing sands, etc.** F. L. WILDER, E. MORRIS, E. SCHIFF and E. S. KING. Brit. 299,750, July 30, 1927. Complex minerals such as Sn-bearing sands are washed or leached with a soln. contg. persulfates and chlorides of an alkali metal, and ferric salts. The very fine particles are thus dissolved out and the residue may be further concd. as by a gravity process. Free Cl may be present in the leaching soln., and when the ore treated contains Fe, at least a part of the ferric salts may be formed *in situ*. In an example, the soln. used contains  $\text{H}_2\text{SO}_4$ , NaCl,  $\text{NaHSO}_4$ , Na persulfate, persulfuric acid,  $\text{FeCl}_3$ ,  $\text{Fe}_2(\text{SO}_4)_3$  and free Cl. Various auxiliary treatments to sep. metals such as Cu and Sn, etc., are described.

**Apparatus for washing titaniferous sand.** MARIUS MILLOT. Fr. 651,838, Mar. 28, 1928.

**Titanium compounds.** TITANIUM PIGMENT CO., INC. (Willis F. Washburn, applicant in U. S.). Fr. 652,357, April 7, 1928. See Brit. 288,569 (C. A. 23, 590).

**Recovery of zinc.** THE RIO TINTO CO., LTD. Fr. 652,367, April 7, 1928. Wash-liquors contg.  $\text{ZnSO}_4$  from pyrites or other ores contg. Zn, or from the ashes from the roasting of these ores, are treated with MgO or  $\text{MgCO}_3$  to ppt. the Zn. The liquor may be passed through layers of calcined MgO or  $\text{MgCO}_3$ .

**Reducing metallic oxides.** ARTHUR J. F. J. COUSIN (to Soc. Anon. John Cockerill) U. S. 1,714,767, May 28. Oxides of relatively heavy non-volatile metals such as Fe and Cu are comminuted and thoroughly mixed with a separately finely comminuted reducing agent such as coal or coke and, after air in this mixt. has been displaced by the addn. of water, the mixt. is compressed to expel remaining traces of air; the compressed mixt. is subjected to the action of a neutral flame at a temp. sufficient to produce a reducing action but below the temp. of fusion of the metal in a neutral atm. having no oxidizing effect on the solid metal at the temp. of treatment.

**Reducing metallic oxides.** SIGURD WESTBERG. U. S. 1,715,155, May 28. Oxides such as those for making Fe and Cr alloys together with solid carbonaceous matter such as ferro-Cr high in C and a H-contg. gas are heated in a reaction zone to effect reaction and conversion of most of the carbonaceous material into CO; the carbonaceous material is kept sep. from the molten metal produced; proportions are controlled to produce a max. yield of metal of the desired C content. An app. is described. Cf. C. A. 23, 366.

**Extraction of metals.** I. G. FARBERNIND. A.-G. Fr. 652,384, April 7, 1928. Substances contg. Ag, Zn, or Cu are more easily extd. by aq.  $\text{NH}_3$  or  $\text{NH}_4$  salts contg. free  $\text{NH}_3$  if they have been given a preliminary chlorinating treatment at a high temp., e. g., by heating with  $\text{MgCl}_2$  or  $\text{NH}_4\text{Cl}$ .

**Purifying metals such as magnesium and aluminum.** BRITISH MAXIMUM, LTD. Brit. 300,164, Nov. 7, 1927. Light metals such as Mg or Al are filtered through metal gauze coated with an alloy or amalgam having a m. p. below  $190^\circ$ , e. g., an amalgam of Sn 2, Pb 1 and Hg 1 part, or an alloy of Sn, Pb, Bi and Cd.

**Ferrous metals containing molybdenum.** A. KISSOCK (to Climax Molybdenum Co.). Brit. 299,800, Nov. 1, 1927. A Mo compd. such as Mo oxide or sulfide or Ca molybdate is added to a blast-furnace charge to produce a pig iron contg. the desired proportion of Mo. Such pig iron may then be used with other metal for producing Mo-contg. gray, white, malleable, or semi-steel castings, etc. Cf. C. A. 23, 1611.

**"Anti-friction metal."** DONALD C. LEE. U. S. 1,714,679, May 28. Brass 4 and Babbitt metal 1 part are alloyed together.

**Metal fusion.** SOC. ANON. DES HAUTS FOURNEAUX ET FONDERIES DE PONT-A-MOUSSON. Fr. 652,670, Apr. 13, 1928. Metals are fused in a cupola by introducing and burning at the base of the furnace a mixt. of a gaseous or powd. fuel and air in the correct proportions. The coke equally employed may be greatly reduced in amt. or suppressed.

**Molds.** JULES L. F. HARDY. Fr. 652,424, April 10, 1928. Molds for molten

metals, etc., are made from a mixt. of artificial corundum and wood charcoal, with  $\text{Na}_2\text{SiO}_3$  as binding agent.

**Ingot molds.** G. W. NAYLOR, J. F. NAYLOR, W. NAYLOR and C. E. NAYLOR. Brit. 300,033, Dec. 15, 1927. Structural features.

**Centrifugal apparatus for casting ingots, etc.** MANNESMANNRÖHRENWERKE. Brit. 299,869, Nov. 4, 1927. Structural features.

**Casting bronze tubes, etc.** G. BÜHLER. Brit. 299,878, Nov. 4, 1927. A resilient core is formed of a mixt. of sand and sawdust and the sawdust is subsequently burnt out. Brit. 299,879 specifies forming tubes of bronze contg. Cu 90-92 and Sn 10-8% by drawing thick-walled tubes cast in chill molds with resilient cores. Various mech. features are described.

**Casting precious and other non-ferrous metals.** A. M. ERICHSEN. Brit. 299,850, Nov. 2, 1927. Molds are used composed wholly or in part of a metal or alloy, which is a poor heat conductor such as a Ni alloy preferably contg. 35% Ni. Various structural features are specified.

**Furnaces for fusing metallic substances.** AMERICAN RADIATOR CO. Fr. 652,368, April 7, 1928. Combustion chambers are arranged radically and slightly inclined round a central chamber contg. the substance to be heated by the gaseous combustion products.

**Furnace for roasting zinc blend and other sulfur ores.** ERZRÖSTUNG G. M. B. H. Fr. 651,692, Feb. 27, 1928.

**Furnace for melting brass, copper, iron, or other metals.** ADOLPH W. MACHLET. U. S. 1,713,543, May 21. A magazine for loose stock comprises a barrel and a crucible into which the barrel discharges; a furnace surrounds the crucible; the furnace is provided with a constricted vent so that heat is confined in the furnace to produce a metal-melting temp. and this vent discharges into a heating chamber which surrounds the stock supply and preheating barrel. Other structural details are also described.

**Converter with an arrangement for preheating and fusing metal.** D. D. VOEIKOV and P. P. KRSTOVNIKOV. Russ. 5622, June 30, 1928. Constructional features are described.

**Blast furnace.** J. P. DOVEL. Brit. 299,941, Aug. 25, 1927.

**Cast iron.** JOSEF DECHESNE. Fr. 33,763, May 10, 1927. Addn. to 616,240. Molten cast Fe or other metal is degasified by being submitted to agitation as it flows from the furnace by a mech. shaking of the recipient.

**Wrought iron.** ARTHUR J. BRIGGS (to Onondaga Steel Co.). U. S. 1,713,887, May 21. Discrete particles of iron are mixed with slag-forming materials in proper quantities to produce the desired fibrous structure of the iron, and the mixt. is heated to a welding temp. in a rotary elec. furnace from which air is excluded.

**Iron sponge.** SVEN E. SEURIN. U. S. 1,714,280, May 21. See Brit. 296,235 (C. A. 23, 2414).

**Tempering steel.** WERNER STAUFFER. Fr. 651,807, Mar. 27, 1928. See Swiss 126,252 (C. A. 23, 592).

**Preparing silicon steel sheets for electrical purposes.** ALPHONSUS F. MURPHY and WILLIAM JONES (to American Rolling Mill Co.). U. S. 1,714,038, May 21. The sheets are pickled, acid is washed and cleaned away, the sheets are then annealed, cold-rolled and finally re-annealed.

**Heating or burning iron, steel, porcelain, or other materials susceptible to oxidation.** HEINRICH KOPPERS (to Koppers Development Corp.). U. S. 1,713,834, May 21. A reducing atm. is maintained in direct environment of the bodies being heated by coating or otherwise maintaining them in intimate contact with carbonaceous material which is not readily combustible, such as graphite, so as to prevent oxidation without effecting carbonization; this facilitates firing with highest practical efficiency without requiring a fuel-gas surplus and lack of sufficient air for substantially complete combustion of the gas.

**Apparatus, with a rotating holder, for heat treatment of steel balls or other articles.** ALBERT VUILLEUMIER (to New Departure Mfg. Co.). U. S. 1,715,317, May 28. Structural features.

**Composition for cleaning and arsenic-coating ferrous metals.** JAMES H. GRAVELL (to American Chemical Paint Co.). U. S. 1,713,653, May 21.  $\text{H}_3\text{PO}_4$  and an oil-remover such as EtOH and BuOH are used with an As compd. such as Na arsenite from which, on contact, a film of As will plate out on a ferrous metal surface.

**Treating waste iron pickle.** A. J. EVANS. Brit. 299,919, Aug. 8, 1927. Treatment of waste iron pickle with alk. earth carbonate and atm. O is improved by the addn.

of a protective colloid such as liquid glue or size or other colloid not affected by salts of Fe, which promotes sepn. of hydrated ferric oxide by formation of a froth.

**Alloys.** WILLIAM H. GORDON. Australia 15,516, Sept. 7, 1928. A ductile non-magnetic Cu alloy, which is resistant to sea-water and many acids, contains Cu 56.6, Ni 18.882, Mn 1.886, Al 7.544, Zn 13.202 and Sn 1.886%. The Cu is first melted and the other metals are added in the above order, the mass being heated to such temp. as to melt the various components. Australia 15,517 describes an Al alloy which retains a high polish and may be cast and machined and which is unaffected by liquids usually met with in domestic use; it contains Ni 29.813, Mn 0.621, Al 49.667 and Zn 19.875%. The Al is first melted and the other metals are added in the above order.

**Alloys.** THE GENERAL ELECTRIC CO. Fr. 652,201, April 4, 1928. Alloys contg. Ni and Cr are made from the pure metals, preferably in powder, and are obtained by hydrolysis, by heating them in the presence of H, which may be purified by passing it over Cr heated to 700–850°.

**Alloys.** THE INTERNATIONAL NICKEL CO. and NORMAN B. PILLING. Fr. 652,168, Feb. 22, 1928. A small quantity of Ca (0.005–0.5%) is added to Ni or other alloys, preferably just before casting. To prevent a film of oxidized Ca on the surface of the mass a thin layer of siliceous slag is formed on the surface before adding Ca.

**Powdered alloys.** SOC. ANON. DES TRÉFILIERIES ET LAMINOIRS DU HAVRE (ANCIENS ÉTABLISSEMENTS LAZARE WEILLER, SOC. COOP. DE RUGLES and LA CANALISATION ÉLECTRIQUE RÉUNIS). Fr. 652,040, Mar. 30, 1928. Powd. alloys particularly brass or bronze are obtained by heating the powd. metals composing the alloy to a temp. below the f. p. of the alloy desired. The heating is carried out in the presence of protecting or reducing gases.

**Alloys for use as bearing metals.** FIRM OF J. NEURATH (to E. Abel). Brit. 299,773, Oct. 31, 1927. Bearing metals consisting mainly of Pb, Sb and Sn, and contg. also Ni and Cu, with or without other metals such as Fe, Cd, Bi and As, contain at least 1.5 times as much Cu as Ni. The Ni content is preferably 0.7–0.8% and does not exceed 1%. Cf. C. A. 22, 4102.

**Aluminum alloys.** H. C. HALL and T. F. BRADBURY. Brit. 300,078, April 3, 1928. Al alloys are formed contg. Ni 0.2–1.5, Mg 0.2–5.0, Cu 0.5–2.0, Si 0.2–0.5, Fe 0.7–1.5% and up to a total of 0.25% of Mn and Ti, which are added as cleansing agents.

**Alloy of beryllium, iron and chromium.** GEORGE G. MARSHALL and HAROLD S. BOOTH. U. S. 1,713,766, May 21. An alloy which is suitable for making carburizing boxes, etc., used at high temps. comprises Be 2–12, Fe 46–90 and Cr 4–42%.

**Copper-aluminum-cerium alloy.** FREDERICK J. READ (one-half each to Calaveras Iron and Steel Co. and Sydney H. Demarest). U. S. 1,714,729, May 28. An alloy which is suitable for journals and bearings comprises Cu together with Ce 0.1–10 and Al 5–10%.

**Iron alloy.** OESTERREICHISCHE SCHMIDTSTAHLWERKE A.-G. Fr. 652,621, April 12, 1928. A fusible alloy of Fe which is resistant to acids contains Ni more than 30, Cr more than 20 and C 0.5–1%, preferably with the addn. of metals such as Mo, which make the working of the metal easier. A reducing agent such as V may also be added.

**Decarbonizing iron alloys.** ELECTRO METALLURGICAL CO. Fr. 652,266, April 5, 1928. Alloys of Fe such as ferrochromium are decarbonized by a blast richer in O than air, e. g., contg. 50% O, which is directed on to the molten surface of the alloy. The alloy may afterwards be blown with H, which is directed under the surface.

**Alloys of nickel and iron, etc.** A. B. DAVIS (to Barber Asphalt Co.). Brit. 300,248, Nov. 10, 1927. Alloys are formed composed mainly of Ni and Fe, contg. also Cr and small proportions of Si and Mn with or without W, Co and Cu. Brit. 300,249–50 also relate to similar alloys with the constituents in different proportions.

**Ferrous alloy containing tin and aluminum.** LEWIS W. MALLASEE (to William H. Mallasee). U. S. 1,714,177, May 21. Sn 2.5 and Al 2.5 or more are added to molten ferrous metal such as steel 1600 parts while the metal is at a pouring temp., in order to form an alloy which is tough, strong, resonant and capable of taking a high temper.

**Alloys of lead with alkali and alkaline earth metals.** I. G. FARBENIND. A.-G. Brit. 300,129, Nov. 5, 1927. Alloys of this class are homogenized by extrusion through a perforated plate. An alloy of Pb with 20% Na, with or without 0.4% Ba, may be extruded at 260–330° in rod or tube form.

**Bronze.** SAARBRÜCKER METALLGUSSEWERK G. M. B. H. Fr. 652,400, April 10, 1928. Bronzes for bearings, etc., contg. 2–12% Pb have added thereto Ni 0.5–8, Cr 0.5–1.5, Mn up to 9, Al up to 5 and Mg 0.15–2% in the presence of metalloids such as As, Si, S, P and Cu, which may be present either singly or together in amt. up to 5%.

**Protecting metals.** GILBERT MICHEL. Fr. 33,706, Mar. 12, 1927. Addn. to

607,663. Metals such as Mg, Al or Ca are protected by a varnish such as a synthetic resin varnish contg. free phenol. Cf. C. A. 23, 369.

**Protecting metals.** GEORGES NOBILLEAU and JOCELYN GUIPET. Fr. 651,850, Mar. 28, 1928. Fe and Cu metals are protected against atm. corrosion by cementation under pressure with powd. Zn contg.  $\text{BaCO}_3$  and (or)  $\text{K}_4\text{Fe}(\text{CN})_6$  and flint.

**Coating objects.** E. I. DU PONT DE NEMOURS & Co. Fr. 652,006, Mar. 30, 1928. In coating surfaces, particularly metals, the primary coating contains a mixed ester of a polyhydric alc. and a polybasic acid and drying oil acids, with or without a natural resin and natural resin acid. Coats of different compn. from the primary are then applied. Examples are given.

**Corrosion preventing.** I. G. FARBENIND. A.-G. Fr. 652,598, April 12, 1928. Corrosion of Fe or its alloys by  $\text{H}_2\text{SO}_4$  of any concn. is lessened by adding to the acid small amts. of thiosemicarbazide or its derivs. A table is given showing the effect of the addn. of thiosemicarbazide, phenylthiosemicarbazide and hydrazinethiodicarboxamide.

**Restricting corrosion of magnesium and its alloys.** ARTHUR C. ZIMMERMAN (to Dow Chemical Co.). U. S. reissue 17,309, May 28. Reissue of original pat. No. 1,677,667 (C. A. 22, 3128).

**Testing the resistance of ferrous metals to rusting.** CARL MAULER. U. S. 1,714,035, May 21. The affinity of O to iron, steel and iron alloys is detd. by immersing the specimens to be tested in a hot oxidizing soln. such as a soln. formed from NaOH,  $\text{NaNO}_3$  and lime and measuring from time to time the temp. of the soln. in order to det. the temp. at the moment at which the surface of the immersed specimen combines with the O of the soln. Cf. C. A. 23, 1382.

**Chromium-plated copper used as fuse wires or strips.** C. W. COX and C. E. C. SHAWFIELD. Brit. 300,160, July 27, 1927.

**Apparatus for cleaning metal sheets or strips by liquid baths.** CLIFFORD B. HIGGINS, HARRY A. HIGGINS and JOHN TYLER. U. S. 1,714,668, May 28. Structural features.

**Split rings for roller bearings.** JOSEPH G. AYERS, JR. (to General Motors Corp.) U. S. 1,715,268, May 28. In making a split ring with a hard raceway surface suitable for roller bearings, cold rolled steel in its flat condition is heat-treated and quenched to produce a hard surface with minimum distortion; the hardened strip is further heat-treated to produce a homogeneous and uniform grain structure, the strip is rolled to remove distortion and is bent into the required form.

**Annealing ferrous metal strips.** HARRY M. NAUGLE and ARTHUR J. TOWNSEND (to Columbia Steel Co.). U. S. 1,714,040, May 21. The metal is heated in a non-oxidizing gas to an annealing temp. and then cooled to below  $100^\circ$  while still in the non-oxidizing gas, all during a continuous endwise movement of the strip. An app. is described.

**Composition for use in soldering or welding aluminum.** WILHELM REUSS. U. S. 1,711,445, May 21. See Ger. 468,540 (C. A. 23, 1100).

**Soldering.** KARL SCHUMPELT (to Ernst G. Bek). U. S. 1,713,677, May 21. The surfaces to be soldered are brought together, and there is deposited on them, without the use of external electric current, such an amount of solder as can be absorbed by the metal of the article, during the subsequent heating operation without substantially changing the color of the article; finally, the solder is heated to cause it to melt and to be absorbed by the metal of the article.

## 10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

**Determination of parachors of substances in solution.** DALZIEL L. HAMMICK and LESLIE W. ANDREW. *J. Chem. Soc.* 1929, 754-9.—Parachors ( $P_m$ ) of solns. have been detd. with the aid of the formula  $P_m = M_m \gamma^{1/2} / (D - d)$  where  $\gamma$ ,  $D$  and  $M_m$  are the surface tension, d., and mean mol. wt. of the soln.;  $d$ , the vapor d. being negligible (at  $25^\circ$ ).  $P_x$ , the parachor of the solute, may be calcd. from  $P$ , the known parachor of the solvent, and  $P_m$  by the formula  $P_m = P(1 - x) + P_x x$  assuming  $P$  obeys the straight-line mixt. law, where  $x$  is the mol. fraction of solute. Surface tensions were detd. using Sugden's app. (C. A. 18, 1771), and  $P_x$  calcd. for the following solns.:  $\text{CCl}_4$ ,  $m\text{-C}_6\text{H}_4\text{Me}_2$ , cyclohexane,  $\text{CHCl}_3$ ,  $\text{EtOH}$ ,  $\text{AcOH}$ ,  $\text{Me}_2\text{CO}$ ,  $\text{PhNO}_2$ ,  $\text{MeNO}_2$ ,  $\text{PhAc}$  and  $\text{Et}_2\text{O}$  in  $\text{PhH}$ ;  $\text{PhNO}_2$  and  $\text{AcOEt}$  in  $\text{CCl}_4$ ;  $\text{AcOEt}$  and  $\text{Me}_2\text{CO}$  in  $\text{HOAc}$

and in EtOH. Excellent agreement was found between exptl. and calcd. values for  $P_x$  and they are generally independent of diln. However, in all mixts. tried contg. nitro compds. and with Et<sub>2</sub>O in PhH,  $P_x$  was a direct linear function of diln. passing through the true parachor (within 1%) at  $x = 1$ . It is thus possible to det.  $P$  for substances which are not stable above their m. p.

A. S. CARTER

**Mechanism of the vapor phase oxidation of isomeric octanes. I. Normal octane.** J. C. POPE, F. J. DYKSTRA AND GRAHAM EDGAR. *J. Am. Chem. Soc.* 51, 1875-89 (1929).—The vapor-phase oxidation (dynamic method) of C<sub>8</sub>H<sub>18</sub>, C<sub>8</sub>H<sub>18</sub>CHO and PrCHO has been studied in detail. The results may be simply interpreted on the theory that the initial oxidation product of C<sub>8</sub>H<sub>18</sub> is C<sub>7</sub>H<sub>16</sub>CHO, which in turn is further oxidized to aldehydes of successively smaller no. of C atoms, CO and some CO<sub>2</sub> being simultaneously formed. The existence of luminescent "chain" reactions is indicated, apparently corresponding to the oxidation of the aldehydes to lower aldehydes, CO and H<sub>2</sub>O. The results are given in curves, for which the original should be consulted.

C. J. WEST

**Characteristics of the non-explosive oxidation of propane and the butanes.** ROBERT N. PRASE. *J. Am. Chem. Soc.* 51, 1839-56(1929).—A study has been made by the flow method of the reactions of mixts. of O with C<sub>3</sub>H<sub>8</sub> and the C<sub>4</sub>H<sub>10</sub>. No attempt has been made to analyze the liquid products and all conclusions are based on the results of gas analyses. The reactions are classified into 3 types which (with examples) are as follows: (I) unsaturates by dissocn. (C<sub>3</sub>H<sub>8</sub> → C<sub>3</sub>H<sub>6</sub> + H<sub>2</sub>); (II) unsaturates by oxidation (C<sub>3</sub>H<sub>8</sub> + 0.5 O<sub>2</sub> → C<sub>3</sub>H<sub>6</sub> + H<sub>2</sub>O); (III) aldehyde reaction (C<sub>3</sub>H<sub>8</sub> + 2 O<sub>2</sub> → CO + 2 H<sub>2</sub>O + AcH). Types I and II give evidence of being more or less normal homogeneous gas reactions which appear at 500-600°, but are subject to induction by Type III at lower temps. in amt. increasing with the temp. Type III may begin at temps. of 300-50° and gives every indication of being a chain reaction. Its development is highly spontaneous and at the same time it is sensitive to relatively minor variations in the conditions of reaction. In particular, it is subject to suppression by a broken-glass packing (especially when this is coated with KCl) and by use of a reaction tube of small diameter. Lowering the pressure to a few mm. has a like effect. Diln. with O, CH<sub>4</sub>, N, CO<sub>2</sub> or H depresses the reaction in amt. increasing in the order named; this effect is the greater at higher temps. Under these conditions the reaction thus has a negative temp. coeff., though eventually becoming explosive. Excess of hydrocarbon promotes the reaction. Under suppression, there may be no reaction up to 500-600°, Types I and II then appear, accompanied by Type III in varying amt. Considerations bearing on the isolation of particular reactions are set forth.

C. J. W.

**Low-temperature oxidation of hydrocarbons. I. The pressure-temperature curves of amylene-oxygen mixtures.** J. STANLEY LEWIS. *J. Chem. Soc.* 1929, 759-67, cf. C. A. 21, 3180.—C<sub>5</sub>H<sub>10</sub> (I) was washed with acidified KI, dried over CaCl<sub>2</sub> and distd., the fraction b. 34-5° being collected. Varying quantities of I were introduced into O<sub>2</sub>-filled bulbs which were connected to manometers. These were slowly heated and the vol. was held const. by varying the Hg head on the manometer, the pressure being recorded against the temp. The curves so formed show 3 sections: (a) a region approximating the normal vapor pressure curve but deviating slightly; (b) a gradual drop in pressure to a min. point indicating slow reaction with decrease in the no. of mols; (c) a sharp rise due to decompn. of products formed in (b), followed by a nearly normal gas pressure. Analyses during (a) gave pos. evidence of reaction with the formation of CO, CO<sub>2</sub> and aldehydes; the amt. increasing with the % of I up to equimol quantities of I and O<sub>2</sub>, above which it again decreased. The min. of (b) varies from 240° with 17.8% of I to 237° with 62.2% of I and the pressure drop is greatest in the equimol. mixt. I. suggests that peroxides (II) formed dissoc. and decomp. to aldehydes during (a); increase of temp. increases their formation and also the decompn. which results in polymerized aldehydes; hence the drop in pressure during (b). At the min. point sufficient unstable material is present to set up chain reactions giving rapid oxidation. Addn. of 0.5% PbEt<sub>4</sub> gave a linear relation between pressure and temp., the contraction disappearing; at the end, CO and CO<sub>2</sub> proved that slow reaction had taken place. H<sub>2</sub>O increased the pressure above the normal probably because of decompn. of II. The same effect was produced to a greater extent by pumice and charcoal, a light depression being observed, followed by detonation at 240° and 222° with pumice and charcoal, resp. The evidence supports the idea that the combustion of a hydrocarbon is the oxidation of a primarily formed unsatd. compd. to II which decomp. to give products which are further oxidized to CO, CO<sub>2</sub> and H<sub>2</sub>O, by virtue of energy from the decompn. of II.

A. S. CARTER

**Aliphatic diolefins. I. Behavior of Δ<sup>1,4</sup>-hexadiene towards sulfuric acid** FRANK

CORTESE. *Ber.* 62B, 504-9(1929).—The chief products of the action of  $\text{H}_2\text{SO}_4$  on  $\Delta^{1,5}$ -hexadiene (I) are a *cryst., neutral, cyclic monoester* (II),  $\text{MeCH}_2\text{CH}_2\text{CH}_2\text{CHMe} \cdot \text{O} \cdot \text{SO}_3\text{H}$ , and a *di-ester* (III),  $(\text{CH}_2\text{CHMeOSO}_2\text{H})_2$ , of

hexane-2,5-diol (IV). Both are unstable and yield IV on hydrolysis. IV is likewise unstable in the presence of acids and is dehydrated with formation of  $\alpha, \alpha'$ -dimethyl-tetrahydrofuran (V) and diallyl oxide (VI). VI in turn is readily attacked and forms condensation products (hydrocarbons) of high mol. wt. The yields of esters, ether and condensation products depend on the concn. of the acid and the temp. I (15 cc.) is added in the course of 25–100 mins. to 13.3 cc. 100%  $\text{H}_2\text{SO}_4$  at  $-15^\circ$  to  $4^\circ$ , treated with ice after 10 mins. to 2 hrs. and the tar filtered off on a glass filter. The filtrate (VII) soon becomes pink. The tar, stirred under ice water, changes into a white powder (II) and the  $\text{H}_2\text{O}$  soln. (VIII) assumes a deep, dark lavender color. The well-washed powder, dried in the air, has a refreshing odor reminiscent of caramel and pepper, m.  $90^\circ$  (cor.) after 15 crystals from  $\text{Me}_2\text{CO}$  with charcoal, is a little hygroscopic and somewhat volatile, mol. wt. in freezing  $\text{C}_6\text{H}_6$  185, is insol. in dil.  $\text{NaOH}$ , is not acid to phenolphthalein, does not at once decolorize a very faintly yellow soln. of Br in  $\text{CCl}_4$ ; crystallographic data (by GUILLERMO ZULOAGA), biaxial negative,  $\alpha_D -50^\circ$ , refractive index  $\beta = 1.505$ , double refraction  $\approx 0.009$ , monoclinic system, extinction  $43^\circ$ . The lavender soln. VIII becomes red-violet in a few days, then blood-red, and deposits a tar; alkalies change the color to a light green-yellow and acids back to the original color, spontaneous evapn. or pptn. with excess of acid gives a purple tar insol. in alc. and sol. in  $\text{Et}_2\text{O}$  and  $\text{Me}_2\text{CO}$ , while in alk. soln.  $(\text{NH}_4)_2\text{SO}_4$  ppts. a green tar with opposite solubilities. All of the tar in colloidal suspension can be brought down with  $\text{BaSO}_4$  by adding  $\text{Ba}(\text{OH})_2$ . The tar consists of condensation products of VI; the "acid" can be converted into the "alk." tar, and *vice versa*. The pink filtrate VII contains 4–8 cc. VI and III; it is neutralized with  $\text{Ba}(\text{OH})_2$  at  $10^\circ$ , freed from the excess of Ba with  $\text{CO}_2$  and concd. at  $45\text{--}55^\circ$  under 10–5 mm., giving 7–8 g. of the *Ba salt*,  $\text{C}_6\text{H}_{12}\text{O}_8\text{S}_2\text{Ba}$ , of III, at once decomps. in a drying oven into tar, VI,  $\text{SO}_2$ , and  $\text{BaSO}_4$ ; even in a glass-stoppered bottle *in vacuo* over lime in the dark it decomps. completely in a few days; on boiling in  $\text{H}_2\text{O}$  it yields  $\text{BaSO}_4$ , the amt. of which corresponds exactly to the increase in acidity. These results indicate that the salt obtained by Béhal from the product of the reaction of I with  $\text{H}_2\text{SO}_4$  was not a sulfonate  $\text{HOCH}_2\text{CH}(\text{SO}_3\text{ba})\text{CH}_2\text{CH}_2\text{CH}:\text{CH}_2$  but  $\text{MeCH}(\text{OSO}_3\text{ba})\text{CH}_2\text{CH}_2\text{CH}(\text{OH})\text{Me}$ , mixed with the above salt of III. When the reaction between I and  $\text{H}_2\text{SO}_4$  is carried out at  $-10^\circ$  the formation of tar is reduced to a min. and III seps. as an almost white ppt.; at  $20\text{--}40^\circ$ , on the other hand, neither VI nor esters are formed, the product being a dark red viscous oil which behaves like the above "acid" tar. The min. concn. of  $\text{H}_2\text{SO}_4$  which will attack I at room temp. is 65%; after shaking 18 hrs. 50 cc. of I yields 25 cc. VI and 10 cc. of red condensation products; the esters are completely decompd. The red polymerization products on distn. under 5 mm. yield 2 cc. of an oil,  $\text{C}_{12}\text{H}_{22}\text{O}$ ,  $b_D^{25} 65\text{--}85^\circ$ , colorless, of pleasant terpene-like odor, absorbs 2 atoms Br,  $d_{25}^{25} 0.865$ ,  $n_D^{25} 1.4536$ , mol. wt. about 180. VI (12 cc.) shaken 18 hrs. with 67%  $\text{H}_2\text{SO}_4$  yields 4 cc. of a deep violet oil giving 1.0 and 0.5 cc. of colorless unsatd. products  $b_D^{25} 55\text{--}7^\circ$  and  $110\text{--}27^\circ$  and having the compn.  $\text{C}_6\text{H}_{10}$ . As the furan ring is easily formed and again easily ruptured, the 1st step in the reaction undoubtedly consists in a rupture of the C–O union and the 2nd possibly in a reorientation of the mols. to  $\text{MeCOBu}$  which is condensed by the acids to unsatd., O-contg. compds. and unsatd. hydrocarbons.  $\text{Me}_2\text{CO}$ ,  $\text{MeCOEt}$ ,  $\text{Et}_2\text{CO}$ ,  $\text{Pr}_2\text{CO}$  and  $\text{MeCOBu}$ , treated like VI above, give deep red, green and purple oils of pleasant odors. C. A. R.

Polymerization of acetylene by electric discharge. Synthesis of dipropargyl and some isomers. GEORGES MIGNONAC and RENÉ VANIER DE SAINT-AUNAY. *Compt. rend.* 188, 959–61(1929).—By means of high-frequency discharge with the electrodes at low temp. ( $-60^\circ$ ),  $\text{C}_2\text{H}_2$  polymerized to give 70% of *trimer*,  $b_{25} -10^\circ$ ,  $d_4^{25} 0.752$ ,  $n_D^{19.5} 1.4446$ , which further polymerized slowly, oxidized at room temp. in air and degraded upon heating. It could be preserved in soln. in  $\text{PhH}$ ,  $\text{Et}_2\text{O}$  or  $\text{CHCl}_3$ . By oxidation with  $\text{KMnO}_4$  or  $\text{O}_3$ , this trimer gave  $\text{HCO}_2\text{H}$ ,  $(\text{CO}_2\text{H})_2$ ,  $\text{EtCO}_2\text{H}$  and  $(\text{CH}_3\text{CO}_2\text{H})_2$ ; hydrolysis of the ozonide gave  $\text{HCHO}$ ; reduction with Pt gave  $\text{C}_6\text{H}_{14}$  and treatment with alc.  $\text{AgNO}_3$  or  $\text{Cu}_2\text{Cl}_2$  indicated a mixt. of 3 constituents, *dipropargyl* (I), *methylpentadiene* (II),  $\text{HC}:\text{C}:\text{CHMeC}:\text{CH}$ , and *1,5,3-hexadiene* (III),  $\text{H}_2\text{C}:\text{C}:\text{CHC}:\text{CH}:\text{CH}_2$ . With  $\text{Cu}_2\text{Cl}_2$ , I gave a ppt. of yellow  $\text{C}_6\text{H}_4\text{Cu}_3 \cdot 2\text{H}_2\text{O}$  and II gave a red ppt. of the same formula; with  $\text{AgNO}_3$ , I and II were pptd. as  $\text{C}_6\text{H}_4\text{Ag}_3 \cdot 2\text{AgNO}_3$ ; in both cases, III remained.

A. S. CARTER

Preparation of butylmagnesium bromide. P. BORGSTROM, F. C. WAGNER AND

H. C. GRIFFIN. *J. Am. Chem. Soc.* 51, 1861-5(1929).—The effect of rate of addn. of BuBr, reverse process of addn., excess of BuBr and excess of Mg on the yield of Grignard reagent has been studied; the yields obtained on the large scale are in close agreement with those obtained by Gilman and co-workers in quant. work on the small scale.

C. J. WEST

Structure and activation of aliphatic aldehyde molecules. II. Formaldehyde, acetaldehyde, propionaldehyde and chloral. SVEND AAGE SCHOU. *J. chim. phys.* 26, 1-43(1929); cf. *C. A.* 23, 2151.—Inertial moments have been calcd. from absorption spectra and used as the basis to calc. the dimensions of the  $H_2CO$  mol. On the assumption that the Y-shaped mol. has an angle of  $60^\circ$  between the legs carrying the H the dimensions are: H to H,  $1.3 \times 10^{-8}$  cm.; C to H,  $1.3 \times 10^{-8}$  cm.; C to O,  $1.09 \times 10^{-8}$  cm. Two fundamental frequencies correspond to the C and O and to the H—H vibrations. In activated mols. the frequencies are decreased and the atoms are farther apart; with increase of temp. the no. of rotational states (no. of lines) is increased. The characteristics of the C:O relation have been likened to the spectrum of Mg, the normal state of which is  $^1S$  and the excited states  $^3P$  (*C. A.* 22, 2325); the electronic states indicate a quadrivalence of the  $H_2CO$  mol., which may be best likened to Si, the normal state being  $3p^2P_{0,1,2,3}$  and the activated  $4s^2P_{0,1,2}$ . AcH vapor shows a 60 band absorption between 3480 A. U. and 3000 A. U.; and below 3000 as far as 2823 A. U., structure is not observed but absorption is evident. Moments were calcd. for AcH and found to be 1.8 times that of  $H_2CO$ , leading to the belief that the rotational axis of the 4 H atoms is about the C—C=O chain which is in a straight line; thus the rotational mass of AcH (4 H atoms) is approx. twice that of  $H_2CO$ . EtCHO shows discontinuous absorption (3406 to 3249 A. U.) in bands which are very close together and difficult to distinguish.  $CCl_3CHO$  shows 2 continuous regions between 3008 and 2693 A. U. The aldehydes observed, with the exception of  $CCl_3CHO$ , showed discontinuous absorption, the structure of the spectra, however, decreasing with increase in the no. of C atoms in the mol. III. Absorption spectra of solutions. *Ibid* 69-90—A soln. of monomol.  $H_2CO$  (I) in  $C_6H_{14}$  was observed at  $-70^\circ$  and found to contain at least 17 bands between 3542 and 2750 A. U., corresponding to 2 states of vibration of the vapor. The max. for the soln. (2940 A. U.) showed a shift of 5 A. U. toward the red (max. for vapor = 2935 A. U.). Aq. solns. of I and  $(H_2CO)_2$  were identical, both showing an increasing absorption toward the ultra-violet with no band characteristic of :C:O, indicating high % hydration to :C(OH) $_2$ , which was calcd. to be less than 1 mol. of I per 1200 mols. of hydrate or polymer. AcH (II) in  $H_2O$  and  $C_6H_{14}$  gave max. at 2778 and 2934 A. U., resp. (vapor, max. = 2800 A. U.), and from the extinction coeffs. at this point, it is estd. that 26% of II is hydrated in  $H_2O$ . EtCHO gave a max. in  $H_2O$  at 2765 A. U. and in  $C_6H_{14}$  at 2895 A. U.; 50% hydration was indicated. In all cases the  $C_6H_{14}$  solns. gave characteristic max. absorptions in the region of 2900 A. U.; chloral gave exactly 2900 A. U., but in  $H_2O$  this :C:O band was not present, indicating a high degree of hydration. The enol form of the aldehydes (:C. CH(OH)) causes absorption in the region of 2210 A. U.; from the extinction coeff. for an aq. soln. of II at this point, it was estd. that 1 mol. in 30,000 was enolized (*vinyl alc*). A 0.1 M soln. of II in 0.01 N NaOH absorbed very much more in this region and had an enol ratio of 1:335. Aq. solns. of II and of *paraldehyde* were made just acid with drop of HCl and found to contain enol to the extent of 1:1040 and 1:835, resp. The formation of *crotonaldehyde* is not responsible for these absorptions, for its max. falls at 2000 A. U.

A. S. CARTER

Esters of dimethylethylacetic acid. B. B. CORSON, J. S. THOMAS AND D. D. WAUGH. *J. Am. Chem. Soc.* 51, 1950-1(1929).—Details are given of the prepn. of *tert*-AmCl in 65% yields; the Mg compd. with  $CO_2$  gives 60% of  $Me_2EtCCO_2H$ . The following esters were prepd. with  $H_2SO_4$  as catalyst ( $b_{744}$  (cor.),  $n_D^{25}$  and  $d_4^{25}$  are given): *Me*, 125-5.5°, 1.3991, 0.8943; *Et*, 141.8-2.2°, 1.3989, 0.8601; *Pr*, 164-4.4°, 1.4040, 0.8575; *Bu*, 184-4.7°, 1.4098, 0.8566; *Am*, 202.5-3.5°, 1.4140, 0.8544; *iso-Am*, 192.5-6.5°, 1.4128, 0.8533.

C. J. WEST

The preparation of ethylene glycol, its homologs and derivatives as disclosed in the patent literature. A. ULLRICH. *Metallbörse* 19, 901-3, 957-8, 1013-14(1929).—A review.

W. C. FBAUGH

Dithioformic acid. II. T. G. LEVI. *Atti accad. Lincei* [6], 9, 170-5(1929); cf. *C. A.* 18, 1114.—The K salt was prepd. by the reaction  $CHCl_3 + 2K_2S = HCS_2K + 3KCl$  (in EtOH); the salt purified by recrystg. from abs. EtOH in dry air, forms golden yellow crystals, m.  $193^\circ$  (decompn.) to a red liquid. The free acid is obtained by adding dil. HCl to the EtOH soln. cooled with ice, as a white solid, insol. in common solvents. There is a slight evolution of  $H_2S$  during the reaction. The acid is collected

on a filter and washed with EtOH, then Et<sub>2</sub>O; it m. 55–60° (decompn.). The NH<sub>4</sub> salt is formed by titrating the acid with NH<sub>4</sub>OH; this decompn. on standing (2HCS<sub>2</sub>·NH<sub>4</sub> = 2NH<sub>3</sub> + H<sub>2</sub>S + (HCS<sub>2</sub>)<sub>2</sub>S). (NH<sub>4</sub>)<sub>2</sub>S does not react directly with CHCl<sub>3</sub>. When the free acid is heated the decompn. products are H<sub>2</sub>S, CS<sub>2</sub>, C and S. (HCS<sub>2</sub>Me)<sub>2</sub> is formed in 70% EtOH by the reaction of MeI on HCS<sub>2</sub>K, as a white solid, which, when decolorized with animal charcoal and recrystd., m. 105.5°. F. p. detns in C<sub>6</sub>H<sub>6</sub> give a mol. wt. 267–276, i. e., the trimeric formula as above. The Et ester is a liquid at ordinary temps. The Pr ester, m. 38–9°; here again we have (HCS<sub>2</sub>Pr)<sub>2</sub>. (HCS<sub>2</sub>Bz)<sub>2</sub> exists in 2 forms, one m. 77°, the other m. 154.5°. The two are sepd. by dissolving in C<sub>6</sub>H<sub>6</sub> and adding EtOH, which ppts. the isomer, m. 154.5°. Both of these also have the mol. wt. 504 of a trimer. (HCS<sub>2</sub>)<sub>2</sub>S is formed by the reaction 2HCS<sub>2</sub>K + BrCN = KCNS + (HCS<sub>2</sub>)<sub>2</sub>S. This, as well as the disulfide, is insol. in common solvents.

A. W. CONTIERI

**New syntheses of organic selenium compounds.** QUINTINO MINGOIA. *Gazz. chim. ital.* 58, 667–73 (1928).—The discovery that HSeMgBr is a valuable agent for the synthesis of a wide variety of org. Se compds. (C. A. 21, 1104) led to further expts. with AcCl, ClCO<sub>2</sub>Et, EtI, AcH and BzH. Freshly distd. AcCl (7.8 g.) in anhyd. Et<sub>2</sub>O added to HSeMgBr (from 2.4 g. Mg and 11 g. EtBr), heated 4 hrs. on a water bath, cooled, decompd. with ice, the 2 layers sepd., and the Et<sub>2</sub>O layer let stand, deposits Se, probably originating from decompn. of AcSeH by atm. O. If the Et<sub>2</sub>O layer is immediately extd. with NH<sub>4</sub>OH, and the ext. (pomegranate-red soln.) evapd. *in vacuo* over H<sub>2</sub>SO<sub>4</sub>, the residue contains Se, AcOH and NH<sub>4</sub> salts, because of oxidation, thus: AcSeNH<sub>4</sub> + O → AcONH<sub>4</sub> + Se. Attempts to prep. salts of heavy metals gave ppts. which formed slowly when cold and rapidly when hot, but which decompd. to the corresponding selenides. There were thus obtained from Pb(OAc)<sub>2</sub> a white ppt. when cold, a black ppt. when hot; from AgNO<sub>3</sub> a white ppt. when cold and a black ppt. when hot; from Bi(NO<sub>3</sub>)<sub>3</sub> a canary-yellow ppt. when cold and a black ppt. when hot; from FeCl<sub>3</sub> a brown-red ppt. when cold and a black ppt. when hot; from CuSO<sub>4</sub> no ppt. when cold and a black ppt. when hot. With Co, Ni, Sn and Zn salts no ppts. were obtained. This decompn. to black selenides when hot is analogous to the corresponding decompn. of thioacetates to sulfides (cf. *Gazz. chim. ital.* 25, i, 314 (1895); 27, i, 316 (1897)). Freshly distd. ClCO<sub>2</sub>Et (10.8 g.) in anhyd. Et<sub>2</sub>O heated 4 hrs. on a water bath with HSeMgBr (from 2.4 g. Mg and 11 g. EtBr), cooled, decompd. with ice, the aq. layer acidified with dil. H<sub>2</sub>SO<sub>4</sub>, the layers sepd., the aq. layer extd. with Et<sub>2</sub>O, the combined Et<sub>2</sub>O exts. treated with concd. NH<sub>4</sub>OH, gave 2 solns. (1) *The ammoniacal soln.* evapd. *in vacuo* over H<sub>2</sub>SO<sub>4</sub>, the residue dissolved in water, acidified with dil. H<sub>2</sub>SO<sub>4</sub>, extd. immediately with Et<sub>2</sub>O, the ext. evapd. *in vacuo* over H<sub>2</sub>SO<sub>4</sub>, yields a small quantity of a compd. contg. Se, m. 122–3°. (2) *The Et<sub>2</sub>O soln.* treated with NH<sub>3</sub>, concd. on a water bath, the residual oil fractionated twice, yields a major part as an oil, b. 125–7°, of characteristic odor and neutral reaction, the analysis corresponding to *monoethylselenocarbonic acid anhydride* (EtOCO)<sub>2</sub>Se. Therefore, if EtOCOSeH is formed, the greater part decompn. as follows: EtOCOSeH → CO + Se + EtOH. This decompn. was confirmed by identification of CO, Se and EtOH in the reaction products. Dry HSeMgBr heated with EtI for 6 hrs. on a water bath, cooled, decompd. with ice, neutralized with dil. H<sub>2</sub>SO<sub>4</sub>, extd. with Et<sub>2</sub>O, the ext. concd. and the residual oil fractionated, yields for the most part EtSeH, the reaction being EtI + HSeMgBr → MgBrI + EtSeH. Freshly distd. AcH (4.4 g.), heated with HSeMgBr (as before) for 4 hrs. on a water bath, cooled, decompd. with ice, neutralized with dil. H<sub>2</sub>SO<sub>4</sub>, the 2 layers sepd., the aq. layer extd. with Et<sub>2</sub>O and the Et<sub>2</sub>O-exts. concd., yields a reddish yellow oil with a disagreeable penetrating odor, which on heating or *in vacuo* decompn. with sepn. of red Se. Let stand several days *in vacuo* over H<sub>2</sub>SO<sub>4</sub>, an uncrystallizable mass was obtained, analysis of which indicated C<sub>2</sub>H<sub>4</sub>Se, so that the reaction is probably in 2 stages, thus: AcH + HSeMgBr → MeHC(SeH)OMgBr + H<sub>2</sub>O, and MeHC(SeH)OH·H<sub>2</sub>O → MeHCSe. To transform the MeHCSe obtained into the solid modification obtained by Vanino and Schinner (cf. C. A. 9, 1609), it was dissolved in abs. EtOH, the soln. was satd. with HCl gas, evapd. *in vacuo* over H<sub>2</sub>SO<sub>4</sub> and CaO, which yielded a cryst. compd., m. 136° (cf. 139° of V. and S.). Freshly distd. BzH (10.6 g.) in anhyd. Et<sub>2</sub>O, heated with HSeMgBr for 10 hrs. on a water bath, and treated as before, yields a small residue insol. in water or Et<sub>2</sub>O. On evapn. the Et<sub>2</sub>O ext. yields chiefly unaltered BzH. On crystn. from boiling C<sub>6</sub>H<sub>6</sub>, the residue insol. in water or Et<sub>2</sub>O yields PhCHSe, m. 203–5°.

C. C. DAVIS

Dioxan. W. HERZ AND ERWIN LORENTZ. *Z. physik. Chem., Abt. A*, 140, 406–22 (1929); cf. C. A. 21, 1095.—The com. product is dried with Na and by fractionation dioxan is obtained, b<sub>760</sub> 100.8°. From the d. at different temps. d<sub>4</sub><sup>20</sup> 1.0548, d<sub>4</sub><sup>100.3</sup> 0.9457,

and the crit. temp.  $310^{\circ}$  are calcd. On mixing with  $H_2O$  contraction, whereas with MeOH and EtOH dilatation, takes place. The abs. viscosity at  $20^{\circ}$ , 0.01255, changes to 0.00539 at  $80^{\circ}$ . The influence on the viscosity by  $H_2O$ , MeOH and EtOH is very specific for each system. The surface tension from  $20^{\circ}$  to  $90^{\circ}$  is detd. and changes from 35.42 to 25.97 dyne/cm. Mixts. with  $H_2O$  have decreasing surface tension with decreasing  $H_2O$  concn. With the alcs. the opposite is found. The sp. heat  $c_p$  detd. at  $23^{\circ}$  is 0.420. The heat of evapn. is 86.2 cal. per g. The b. p. const. is 3270 and not 2200. The lowering of the f. p. by  $C_{10}H_8$  gives 5010 for the const. In  $C_8H_8$  dioxan is monomol. The heat of combustion is 6602 cal. per g. The solubilities of different inorg. and org. salts in dioxan- $H_2O$  mixts. are given, also some cond. measurements.

E. SCHOTTE

**Mechanism of organic reactions. II.** The "non-existence" of a migratory methyl group in the conversion of glycerol dichlorohydrin into glycerol monomethyl ether. HAROLD HIBBERT and MYRON S. WHELEN. *J. Am. Chem. Soc.* 51, 1943-7 (1929); cf. C. A. 23, 2939.— $CH(OH)(CH_2Cl)_2$ , MeI and AgO give glyceryl  $\alpha,\alpha'$ -dichlorohydrin  $\beta$ -Me ether (I), b.  $157-9^{\circ}$ ,  $n_D^{17}$  1.4550; hydrolysis by heating with AcO and 75% EtOH for 16 hrs. at  $115-30^{\circ}$  and then heating the filtrate 1 hr. with 75% EtOH contg. 3% HCl gives only MeOCH( $CH_2OH$ ) $_2$ . Allyl Me ether and Cl at  $0^{\circ}$  give glyceryl  $\alpha,\beta$ -dichlorohydrin  $\alpha'$ -Me ether, b.  $153-7^{\circ}$ ,  $n_D^{17}$  1.4489; conversion into the acetate and sapon. yields only the  $\alpha$ -Me ether. Previous work in this field, pointing to the probability of the migration of a Me radical in the conversion of I into the acetate and subsequent hydrolysis of the latter, is based on the mistaken identity of the resulting product as the  $\alpha$ -Me ether. The bearing of these results on the methylation of  $C_3H_5(OH)_3$  and carbohydrate derivs. is pointed out and the importance of the pure  $\alpha$ - and  $\beta$ -glyceryl Me ethers as "type substances" further confirmed. C. J. W.

**Further syntheses of  $\alpha$ -keto acids of the carbohydrate series.**  $\alpha$ -Ketogalactonic or  $d$ -tagaturonic and  $\alpha$ -ketomaltobionic or  $d$ -glucosido- $d$ -fructuronic acids. TORAO KITASATO. *Biochem. Z.* 207, 217-29 (1929).— $d$ -Galactosone is oxidized with  $Br_2$  to  $\alpha$ -keto- $d$ -galactonic acid which is isolated as the Ca salt from MeOH, which in turn can be converted into the Ba salt and pptd. from EtOH. Both salts are  $H_2O$ -sol. The Ba salt is converted to a brucine salt also easily sol. in  $H_2O$ , but not in abs. alc. or  $Me_2CO$ . Recrystd. several times from acetone, this salt has  $[\alpha]_D^{21} -24.55^{\circ}$  in  $H_2O$  and  $-24.39^{\circ}$  in 50% alc. Its isomer,  $d$ -tagaturonic acid, in an equiv. amt. of HCl, has  $[\alpha]_D^{21} -7.6^{\circ}$  to  $-7.8^{\circ}$ . The  $\alpha$ -ketomaltobionic acid is prepd. from maltosone by oxidation with  $Br_2$ . The sol. Ba salt is obtained by pptn. with MeOH and is converted to the brucine salt. The latter m.  $150-60^{\circ}$  (decompn.),  $[\alpha]_D^{21} 11.2^{\circ}$  in water and  $16.1^{\circ}$  in 50% alc.  $d$ -Glucosido- $d$ -fructuronic acid is isomeric and its Ba salt in water has  $[\alpha]_D^{20} 54.8^{\circ}$ , and reduces Fehling soln. powerfully. Hydrolysis with acids and enzymes was studied. S. MORGULIS

**Preparation of osone solutions for purposes of synthesizing keturonic acids.** T. KITASATO AND C. NEUBERG. Kaiser Wilhelm-Inst. für Biochem., Berlin-Dahlem. *Biochem. Z.* 207, 230-1 (1929).—The osazones are hydrolyzed with fuming HCl in an ice mixt. and the pptd.  $PhNHNH_2 \cdot HCl$  removed by filtration. From the dark filtrate the HCl is removed by neutralizing with alkali-free  $PbCO_3$ . The  $PbCl_2$  is allowed to crystallize out in the cold, and the soln. is decolorized with charcoal. It is concd. *in vacuo* to give about 2% concn. of osone. On oxidation this yields keturonic acids. S. MORGULIS

**Synthesis of cyclic compounds. V.** The catalytic and the thermal decomposition of some normal dibasic acids. A contribution to the problem of the ease of formation of simple carbon rings. ARTHUR I. VOGEL. *J. Chem. Soc.* 1929, 721-33; cf. C. A. 22, 4481.—V. gives a critical discussion (with many references) of the exptl. and theoretical work on ring formation, particularly Ingold's (C. A. 15, 1696, 3078; 20, 2830) and Wojnicz-Sianozeki's (C. A. 16, 3073). For a study of the ease of formation of simple C rings, V. chose as a suitable reaction the slow thermal distn. of the normal dibasic acids  $(CH_2)_n(CH_2CO_2H)_2$ , which could decomp. to form a ketone,  $CH_2 \cdot (CH_2)_n \cdot CH_2 \cdot CO$ , or a satd. monobasic acid,  $Me(CH_2)_nCH_2CO_2H$ . His results

indicated that the cyclopentane ring is formed more readily than the cyclohexane ring, disagreeing with I.'s theoretical computations, but agreeing with W.-S.'s. The distns. were all carried out by heating slowly in a bath filled with Cu turnings. Glutaric acid (I) (280 g.) and succinic acid (90 g.) were prepd. in 2 expts. from 1 part cyclopentanone (400 g.) and 10 parts  $HNO_3$  (2:3). I on distn. gave butyric acid, b<sub>100</sub>  $160-2^{\circ}$ , d<sub>15</sub>

0.9595,  $n_D^{19.9}$  1.3978. Fifty g. I on catalytic decompn. (meaning always a distn. with Fe filings and Ba(OH)<sub>2</sub> in the proportion of 100 and 5 g., resp., to 100 g. of acid) formed 1.5 g. of a liquid,  $b_{768}$  145–50°. The yields of cyclopentanone from adipic acid under the following conditions were: distd. alone, 80%; distd. with an equiv. amt. of Fe, 61%; with 5% by wt. of Ba(OH)<sub>2</sub>, 78%; on catalytic decompn., 51% (and in addn. probably some cyclopentylidenecyclopentanone). Pimelic acid (II), m. 105–6°, was prepd. most conveniently almost quantitatively by refluxing the dinitrile (from  $\alpha,\epsilon$ -C<sub>6</sub>H<sub>10</sub>Br<sub>2</sub> and alc. KCN) 9 hrs. with 12–15 times its wt. of 50% H<sub>2</sub>SO<sub>4</sub>. On distn. 50 g. II yielded 52% cyclohexanone,  $b_{768}$  155°,  $d_{15.2}$  0.9489,  $n_D^{16.2}$  1.4521 (semicarbazone, m. 166°) and hexoic acid (4.3 g. of the Ag salt). Catalytic decompn. of II gave chiefly cyclohexanone (56%). The yields of suberone and heptoic acid on distn. of 50 g. suberic acid, under the following conditions were, resp.: alone, 0.9 g., 15.5 g. ( $b_{18}$  120°,  $d_{18.8}$  0.9212,  $n_D^{18.8}$  1.4255); with 5% by wt. of Ba(OH)<sub>2</sub>, about 2%, 12.9 g. ( $b_{18}$  121°,  $d_{17.1}$  0.9231,  $n_D^{17.1}$  1.4265); with 5% by wt. of Fe, 2.5 g. (impure), 8.5 g. ( $b_{18}$  121°); with 0.5 the quantity Fe required to form the Fe<sup>++</sup> salt, 7.7 g., 1.8 g.; with an equiv. quantity Fe, 8 g., 0.1 g. with an equal wt. of Fe, 10 g. suberone. These expts. indicate that increasing the proportion of Fe increases the purity of the suberone, as shown by the b. p., d.,  $n$  (the values are given) and the formation of semicarbazone. An intermediate Fe<sup>++</sup> salt is thought to be formed at a relatively low temp. and to decompose into suberone at a higher temp. Azelaic acid (III), m. 106–7°, (from the oxidation of ricinoleic acid by KMnO<sub>4</sub>; Maquenne, *Bull. soc. chim.* 21, 1061) on distn. gave mainly 1.4 g. of a liquid, b. 180–230° (apparently impure cyclooctanone), and 5 g. octoic acid,  $b_{16}$  129–30°. III on catalytic decompn. for 27 hrs. (the temp. being very slowly raised) formed about 10% cyclooctanone, identified as the semicarbazone, m. 166–7°. Catalytic decompn. of III isolated from the mixed acids (cf. C. A. 22, 4481) gave suberone as the main product. Fifty g. sebacic acid (IV) on distn. gave 0.9 g. of a ketone and 7 g. nonoic acid,  $b_{16}$  142–3°,  $d_{18}$  0.9096,  $n_D^{18}$  1.4343. Catalytic decompn. of IV gave a small yield of Me octyl ketone, identified as the semicarbazone, m. 122–3°.

JANET D. SCOTT

**Configuration determinations of mirror image isomers.** BROR HOLMBERG. *Svensk. Kem. Tid.* 41, 60–73 (1929).—A critical discussion on recent work on *d*- and *l*-isomers of lactic, malic, succinic, etc., derivs., citing Holmberg, Wohl, Freudenberg, Hudson, Levene, *et al.* So far no general method has become available for ascertaining the configurations of mirror image isomers. Those offered are objectively unsatisfactory and allow subjective evaluation of evidence leading to conflicting conclusions. *E. g.*, there is general agreement that *d*-rotatory asparaginic acid is of like configuration to *l*-rotatory malic acid—but the *l*-rotatory halosuccinic acids are classed *d* by Holmberg and Levene and *l* by Freudenberg, etc. Stelling's (C. A. 22, 4056) x-ray spectrographs may possibly give clues to the true configurations.

A. R. ROSE

**Question of the existence of an "activated" form of oxalic acid.** F. KRAUSS AND E. BRUCHHAUS. *Ber.* 62B, 487–9 (1929).—Oberhauser and Hensinger (C. A. 22, 2142) found that, if HgCl<sub>2</sub> is added to dil. solns. of (CO<sub>2</sub>H)<sub>2</sub> or (CO<sub>2</sub>Na)<sub>2</sub> and KMnO<sub>4</sub>, immediately after they have reacted, it is reduced to HgCl if (CO<sub>2</sub>H)<sub>2</sub> is present in excess, a phenomenon which they explain by assuming the formation, after the reaction with KMnO<sub>4</sub>, of an activated form of (CO<sub>2</sub>H)<sub>2</sub> whose activity slowly decreases. K. and B. have been able to confirm these observations without difficulty but they believe the reduction of the HgCl<sub>2</sub> is effected by a decompn. product of the (CO<sub>2</sub>H)<sub>2</sub>, *viz.*, HCO<sub>2</sub>H. HCO<sub>2</sub>H is best detected by adding to the soln. being examd. 5 cc. of 2% HgCl<sub>2</sub> and warming; if HCO<sub>2</sub>H is present a ppt. of HgCl seps. before boiling; if only very little HCO<sub>2</sub>H is present merely a turbidity is formed. If there is no reaction it is well to add another 5 cc. of HgCl<sub>2</sub> as an excess of HgCl<sub>2</sub> is necessary. When mixts. of 200 cc. of 5% (CO<sub>2</sub>H)<sub>2</sub> and 20–30 cc. of 5% KMnO<sub>4</sub> are heated, immediately after decolorization, with 5–10 cc. of 2% HgCl<sub>2</sub>, HgCl is pptd.; moreover, the resorcinol-H<sub>2</sub>SO<sub>4</sub> test gives not only the blue ring of (CO<sub>2</sub>H)<sub>2</sub>, but also, above it, the orange band of HCO<sub>2</sub>H, with gas evolution. Again, if the decolorized mixt. is partly distd. into H<sub>2</sub>O, the distillate gives a turbidity on heating with HgCl<sub>2</sub> and with resorcinol-H<sub>2</sub>SO<sub>4</sub>, shows the orange band of HCO<sub>2</sub>H but no longer the blue ring of (CO<sub>2</sub>H)<sub>2</sub>; 25 cc. distillate from a mixt. of 200 cc. (CO<sub>2</sub>H)<sub>2</sub> and 30 cc. KMnO<sub>4</sub> was neutralized with 0.46–0.50 cc. of 0.1 N NaOH, and the neutralized distillates yielded on evapn. HCO<sub>2</sub>Na, identified by its m. p., mixed m. p. and analysis. (CO<sub>2</sub>H)<sub>2</sub> alone distd. under the same conditions yielded no volatile acid.

C. A. R.

**Preparation of maleic acid by the catalytic oxidation of benzene.** TEIJIRO YABUTA

AND RINTA SIMOSE. *Bull. Inst. Phys.-Chem. Research (Tokyo)* **8**, 197-205 (1929); *Abstracts* **2**, 26 (in English).—In the oxidation of  $C_6H_6$  to maleic acid with air and a  $V_2O_5$  catalyst, Y. and S. study the influence of (a) diluent gases, (b) methods of prep. the catalyst and (c) the influence of acidic metal oxides in the catalyst. G. C.

Dicyanic acid. TENNEY L. DAVIS AND KENNETH C. BLANCHARD. *J. Am. Chem. Soc.* **51**, 1806-9 (1929).—Cyanic acid in  $H_2O$  ionizes as a weak acid, trimerizes to cyanuric acid, which may ppt. out or may appear as a residue when the liquid is evapd., undergoes hydrolysis to produce  $NH_3$  and  $CO_2$  (the  $NH_3$  combines with unchanged  $HOCN$  to form  $CO(NH_2)_2$  and  $NH_4CNO$  in the ratio corresponding to the equil. between these substances), and it dimerizes to form dicyanic acid. Dicyanic acid either depolymerizes during the evapn. of the soln. or undergoes hydrolysis—for an aq. soln. yields only  $CO(NH_2)_2$  and a little cyanuric acid when it is evapd. to dryness. Allophanic esters and biuret are formed directly from the alcs. and from  $NH_3$ , resp., not by the addn of  $HOCN$  to intermediate carbamic esters and  $CO(NH_2)_2$ . Aq. solns. of  $HOCN$  contain some substance, not biuret, which gives a biuret test, which reacts with  $PhNH_2$  to form phenylbiuret and with alcs. to form allophanic esters. C. J. WEST

Dearrangement of nitrobiuret and its application in synthesis. TENNEY L. DAVIS AND KENNETH C. BLANCHARD. *J. Am. Chem. Soc.* **51**, 1801-6 (1929).— $NH_2CONHCONHNO_2$  (I) appears to dearrange in 2 modes, to form  $NH_2NO_2$  and dicyanic acid, and  $O_2NNCO$  and  $CO(NH_2)_2$ . When an aq. soln. is warmed, the  $NH_2NO_2$  evidently breaks down into  $N_2O$  and  $H_2O$ , the  $O_2NNCO$  into  $N_2O$  and  $CO_2$  and the liquid acts toward various reagents as if it contained dicyanic acid. With moist  $EtOH-KOH$  I yields K allophanate, while with moist alcs. it gives allophanic esters which react with the alcs. on refluxing to produce carbamic esters. With  $NH_4OH$  I yields biuret, with biuret, tetruret; with primary and sec. amines,  $\omega$ -substituted biurets. The following  $\omega$ -alkyl- and  $\omega,\omega$ -dialkylbiurets were thus prepd. (m. p. and yield given): Me, 166.5-7°, 12.5%; Et, 154-4.5°, 23.9%; Pr, 147.2-7.6°, 45.0%; Bu, 129.1-9.5°, 70%; benzyl, 174.5-5°, 43%; Ph, 165°, 80%; p-tolyl, 199°, 62%;  $\alpha$ -naphthyl, 217-3-7.6°, 52%; di-Me, 141-1.5°, 33.6%; di-Et, 139-9.2°, 80%; di-Pr, 129-9.4°, 62%; di-Bu, 144.8-5°, 50%; ethylphenyl, 155.2-5.8°, 71%; propylphenyl, 151-1.5°, 45.3%. A soln. of I in concd.  $H_2SO_4$  gives up its  $NO_2$  group quant. in the nitrometer and is a suitable reagent for nitration. C. J. WEST

Dearrangement of nitrourea and its application in synthesis. TENNEY L. DAVIS AND KENNETH C. BLANCHARD. *J. Am. Chem. Soc.* **51**, 1790-801 (1929).— $NH_2CONHNO_2$  (I) dearranges into  $HNCO$  and  $NH_2NO_2$ ; it has been prepd. from these substances and they have been prepd. from it. The products of the decompn. of I by heat are those which would be expected from the 2 possible modes of its dearrangement ( $NH_2NO_2$  and  $HNCO$  and  $NH_3$  and  $O_2NNCO$ ).  $N_2O$  and  $HNCO$  are produced quant. when I is heated with  $H_2O$ . A soln. of I in concd.  $H_2SO_4$  contains  $NH_2NO_2$  and may be used as a reagent for nitrations. Alkalies promote the decompn. of I; acids hinder it. A very slight alk. in the presence of a trace of  $H_2O$  is sufficient to cause its spontaneous decompn. An aq. soln. of I, being a source of  $HNCO$ , reacts with  $NH_3$  and with primary and sec. amines to form  $CO(NH_2)_2$  and substituted derivs. The yields are excellent, the manipulation is simple and the other products of the reaction are gaseous. The method is especially advantageous for the prepn. of those substituted ureas which cannot be heated with  $H_2O$  without decompn. The following compds. were thus prepd.: Methylurea, m. 102° (85% yield); Et deriv., m. 92.1-2.4° (80%); Bu deriv., m. 96° (91%); benzeneazophenylurea, m. 222-3° (3%); ethylenediurea, m. 193-4° (78%); m-uraminobenzoic acid, m. 269.5-70.2° (90%); p-isomer, does not m. 275°; hydantoic acid, m. 160-1° (60%); (Et ester, m. 134-5° (62%)); phenylurea, m. 147° (98%). The following  $\alpha,\alpha$ -dialkylureas were prepd. in essentially the same way: di-Me, m. 182° (88% yield); di-Et, m. 75-5.3° (65%); di-Pr, m. 75.8-6.1° (57%); di-Bu, m. 118-9° (86%) (picrate, m. 82-3°); di-iso-Am, oil (92%) (oxalate, m. 101.5-2.5°; picrate, m. 72.8-3.9°); 2,3,4-trihydroquinolylurea, m. 146.2-6.6° (85%). The following  $\alpha$ -alkyl- $\alpha$ -phenylureas were prepd.: Me, m. 81.8-2.0 (72%); Et, m. 62.3-2.5° (76%); Pr, m. 89.4-9.8° (80%) (picrate, m. 118-8.5°; oxalate, m. 71-2°); Bu, m. 50.1-1.1° (50%). Heating the Pr deriv. at 210-5° gives 94.3% of  $PhNHPr$ .  $\omega,\omega$ -Dipropyl- and  $\omega$ -propyl- $\omega$ -phenylbiuret are obtained as by-products in the prepn. of urea derivs. from I and the corresponding amines. Moist alcs. react with I to produce carbamic and allophanic esters. C. J. WEST

Procedure for a convenient method to prepare salts of methylguanidine which are stable in air. WILHELM TRAUBE AND KURT GORNIAK. *Z. angew. Chem.* **42**, 379-81 (1929).—A 60-70% yield of crude methylguanidine sulfate (I) is obtained when a finely powd. mixt. of 42 g. dicyanodiamide and 87.5 g.  $MeNH_2Cl$  are heated just to the m. p.

(80–110°), then heated for 3 hrs. at 175° (never above 180°), cooled, dissolved in 250 cc. hot abs. alc., allowed to stand 12 hrs., filtered from the 2 g. of melamine-HCl which seps., an aliquot portion taken for detn. of Cl by gravimetric or Volhard method, a quantity of Na equiv. to the Cl in the original soln. dissolved in abs. alc. and added to the original soln. to ppt. NaCl (Soln. I), H<sub>2</sub>SO<sub>4</sub>, then added with cooling until the soln. is neutral which ppts. sulfates, the soln. and ppt. warmed 0.5 hr., filtered, the ppt. dissolved in a little H<sub>2</sub>O, a large vol. of alc. added which causes a ppt. to form as well as 2 immiscible liquid layers, filtered and the ppt. recrystd. from H<sub>2</sub>O; after a recrystn. from H<sub>2</sub>O, it m. 238°; when treated with the calcd. quantity of Ba(NO<sub>3</sub>)<sub>2</sub> in H<sub>2</sub>O, evapd. to dryness and recrystd. from abs. alc., it yields the *nitrate*, m. 148–9°. If Soln. I is neutralized with HCO<sub>2</sub>H, evapd. to a small vol., the sepd. crystals filtered, pressed on a porous plate, dried in a desiccator and recrystd. from alc., it yields the *formate*, m. 122°; the *nitrite* prepd. by treatment of I with Ba(NO<sub>2</sub>)<sub>2</sub>, m. 150°; the *free base* is obtained by treatment of the nitrate in alc. with an equiv. of EtONa and evapg. A 60% yield of *acetylmethylguanidine* (II), m. 171–2°, is obtained by warming the free base with EtOAc and recrystg. from EtOH; *HCl salt*, m. 172°; when II is heated above 171° it yields *dimethylacetoguanamine*, MeC:N.C(NHMe):N.C(NHMe):N. *Benzoylmethyl-*

*guanidine*, prepd. like II from the free base and EtOBz, m. 156°; the HCl salt, m. 220–1°. *Oxalymethylguanidine*, NH.C(:NH).NMe.CO.CO, prepd. by adding (CO<sub>2</sub>Et)<sub>2</sub>

to the free base in EtOH, filtering and recrystg. by adding AcOH to a MeOH soln., m. 205–7°. A 50% yield of *iminomalonylmethylguanidine* was obtained by adding 11.3 g. CNCH<sub>2</sub>CO<sub>2</sub>Et and 2.3 g. Na in abs. alc. to 7.3 g. free base in alc., refluxing 0.5 hr., filtering, neutralizing the filtrate with AcOH, filtering, evapg. the filtrate to dryness, dissolving the residue and previous ppts. in H<sub>2</sub>O, adding an excess of NH<sub>4</sub>OH and recrystg. the ppt. from H<sub>2</sub>O; it crysts. with 1 mol. H<sub>2</sub>O and m. 162° (decompn.); it forms cryst. salts with mineral acids and with HNO<sub>2</sub> yields a red *isonitroso compd.*

N. A. LANGE

**Hydantoins. XLVIII. Synthesis of polypeptide-hydantoins from hydantoin-1-acetic acid.** ALICE G. RENFREW AND TREAT B. JOHNSON. *J. Am. Chem. Soc.* 51, 1784–9(1929); cf. C. A. 23, 820.—Refluxing a mixt. of 7 g. Et hydantoin-1-acetate (I), 6.3 g. *p*-MeOC<sub>6</sub>H<sub>4</sub>CHO, 8 g. AcONa, 12 cc. AcOH and 3 cc. Ac<sub>2</sub>O for 6 hrs. gives 31% of *5-p-anisalhydantoin-1-acetic acid*, crystg. with 1 EtOH, m. 215–6°; heating with HI and red P gives the *5-p-IIO deriv.*, m. 201°. The structures of these compds. were established by methylation and reduction, which give 3-methyl-5-hydroxybenzylhydantoin-1-acetic acid, m. 167°, proving that the CH<sub>2</sub> group in the hydantoin cycle is the reactive complex when brought into reaction with aldehydes. I and MeONa in MeOH give, after digesting with an excess of MeI, *Et 3-methylhydantoin-1-acetate*, m. 91–2°; the free acid and *p*-MeOC<sub>6</sub>H<sub>4</sub>CHO with AcONa in AcOH give 3-methyl-5-*p*-anisalhydantoin-1-acetic acid, m. 203–5°, and also the labile modification, m. 168–9°, the yield of either isomer was small. Neither with hydantoin-1- nor -3-acetic acid was any evidence of the formation of geometric isomers obtained. The biol. importance of hydantoinacetic acids is emphasized and also their possible structural relationship to proteins.

C. J. WEST

**Pyrimidines. CVII. Examination of yeast nucleic acid for 5-methylcytosine.** TREAT B. JOHNSON AND HENRY H. HARKINS. *J. Am. Chem. Soc.* 51, 1779–84(1929); cf. C. A. 23, 2445.—A method for prepg. a protein-free nucleic acid from yeast is described; this is based on the original method of Altmann modified as recommended by Studel. The acetol test for thymine and 5-methylcytosine has been applied to the pyrimidine fraction of yeast nucleic acid and has been found to be negative. It may be concluded, therefore, that neither of these pyrimidines is present in yeast nucleic acid. By application of the acetol test for 5-methylcytosine to the aminopyrimidine fraction of any nucleic acid, it is now possible to detect this substance when present in very minute quantities.

C. J. WEST

The condensation product of glucose and *p*-anisidine. M. AMADORI. *Atti accad. Lincei* [6], 9, 226–30(1929); cf. C. A. 23, 3211.—Equimol. portions of glucose and *p*-anisidine placed in MeOH or EtOH slowly dissolve (8–10 days in MeOH, 15–20 in EtOH) completely, and, on allowing the soln. to evap. spontaneously, give a product, m. 86°. If the same compds. are boiled in the alc. and the product is recrystd., it m. 140°. These 2 forms evidently correspond to the 2 forms obtained when glucose and *p*-phenetidine condense. The compd., m. 86°, in H<sub>2</sub>O [ $\alpha$ ]<sub>D</sub><sup>20</sup> —38°, is quite stable to alkalis, but is decompd. by acids as with phenetidine. The compd., m. 140°, in

$\text{H}_2\text{O}$   $[\alpha]_D^{20} -28^\circ$ , is stable toward acids, and is decompd. to its constituents by alkalis. Therefore, the  $86^\circ$  compd. has the constitution of a glucoside, the  $140^\circ$ , that of a Schiff base.

A. W. CONTIERI

**Optical rotation and atomic dimension. VIII. Haloheptaacetyl derivatives of melibiose and maltose.** The structure of bioses and cellulose. D. H. BRAUNS, *J. Am. Chem. Soc.* 51, 1820-31(1929); cf. *C. A.* 22, 391.—The pure cryst. F, Cl and Br derivs. of acetylated melibiose and maltose have been prepd. The sp. rotational values of these  $\alpha$ -biase derivs. show an agreement with the at. dimension relationship of the monose sugars, whereas the values for the halogen derivs. of the  $\beta$ -biase, investigated before, agree with the relationship only by excluding the values for the F derivs. An explanation of this behavior is obtained by model studies, which show that the direction of the  $\beta$ -valence allows the constituting monoses to face each other, with a resulting selective influence, whereas the direction of the  $\alpha$ -valence does not allow this position. The new (more detailed) structure formula for cellobiose suggests a structure formula for cellulose. As compared with formulas heretofore suggested, this new formula gives a better interpretation of the chem. and phys. properties of cellulose. *Fluoroheptaacetylmellibiose*, prepd. according to B. (*C. A.* 17, 2107), m.  $135^\circ$ ,  $[\alpha]_D^{20} 149.70^\circ$ ; *Cl deriv.*, m.  $127^\circ$ ,  $[\alpha]_D^{20} 192.50^\circ$ ; *Br deriv.*, m.  $116^\circ$ ,  $[\alpha]_D^{20} 209.90^\circ$ . *Fluoroheptaacetylmaltose*, m.  $174-5^\circ$ ,  $[\alpha]_D^{20} 111.1^\circ$ ; *Cl deriv.*, m.  $125^\circ$ ,  $[\alpha]_D^{20} 159.50^\circ$ ; *Br deriv.*,  $[\alpha]_D^{20} 180.10^\circ$ .

C. J. WEST

**Dehydration of cyclohexene oxide and the conversion of the  $\text{C}_6$ -cycle into the  $\text{C}_5$ -cycle.** PIERRE BEDOS AND ADRIEN RUYER. *Compt. rend.* 188, 962-4(1929).—Passing 1,2-epoxycyclohexane (I) over thoria at  $330^\circ$  at the rate of 10-15 drops per min gave 1,2-dihydrobenzene (II), cyclopentane aldehyde (III) and unidentified compds. Dropping I into  $\text{C}_6\text{H}_4(\text{CO})_2\text{O}$  heated nearly to its b. p., gave 15 to 50% of II and 40 to 10% of III, the ratios of II and III varying, resp., with conditions of temp. and rate. This method gave pure II,  $b_{755} 81^\circ$  after distn. Small amts. of III were also formed through the use of  $(\text{CO}_2\text{H})_2$ ,  $\text{KHSO}_4$ ,  $\text{H}_2\text{SO}_4$  or  $\text{P}_2\text{O}_5$  as dehydrating agent. A. S. CARTER

**Action of allyl mustard oil on benzidine.** B. CECCHETTI AND U. SARTI. *Gazz. chim. ital.* 58, 760-3(1928).—The various reactions of thioureas studied by Lellmann and Würthner (cf. *Ann.* 227-8, 206, 209(1885)) and the nature of the products suggested that it was possible to obtain benzidine mustard oil (I) directly from allyl mustard oil (II) and benzidine (III). II (50 g.) refluxed a short time with III (10 g.), cooled, filtered, the residue washed repeatedly with EtOH and then with  $\text{Et}_2\text{O}$  and dried *in vacuo*, yields a compd. (IV) which m.  $243^\circ$ . This shows that I was not formed, in fact, analysis indicated that the product is the bi-addn. product of II and III prepd. by Schiff by another method (cf. *Ber.* 11, 830(1878)). Oxidized with concd.  $\text{HNO}_3$ , IV gives an unidentified bright red compd., m.  $176^\circ$ . II (100 g.) refluxed with III (10 g.) for 4 hrs., and the product treated as before, yields the compd.  $\text{C}_{14}\text{H}_{18}\text{N}_2\text{S}_2$ , m.  $203^\circ$ , which conforms to the properties of the product obtained by Jaffé from  $\text{CSCl}_2$  and III, i. e.  $[\text{SCNC}_6\text{H}_4-]_2$ . No  $\text{H}_2\text{S}$  was evolved in this last reaction, and it is probable that the reaction takes place in 2 steps: (1)  $\text{III} + 2\text{II} \longrightarrow [\text{C}_6\text{H}_5\text{NHCSNHC}_6\text{H}_4-]_2 \longrightarrow [\text{SCNC}_6\text{H}_4-]_2 + 2\text{PhNH}_2$ .

C. C. DAVIS

**Action of carbon disulfide on benzidine in the presence of metallic oxides.** B. CECCHETTI AND U. SARTI. *Gazz. chim. ital.* 58, 758-60(1928).—In a study of methods of removing  $\text{H}_2\text{S}$  from the sphere of action in the formation of thioureas from  $\text{CS}_2$  and amines and thus rendering the reaction quant., Krulla (cf. *C. A.* 8, 100) found that with  $\text{Sn}(\text{OH})_2$  an intermediate product of the dithiocarbamate type, e. g.  $(\text{PhNHCSS-})_2\text{Sn}$ , was formed. On the other hand, with other metallic compds. no intermediate compds. were formed. It was therefore of interest to det. whether with the method of K., compds. of the type  $(\text{RNHCS})_2$ , could be obtained, perhaps with formation of intermediate products. Alc. benzidine agitated for several hrs. with  $\text{CS}_2$  and fresh dry  $\text{SnO}$ , filtered, washed with EtOH and  $\text{Et}_2\text{O}$ , the residue treated repeatedly with concd.  $\text{HCl}$ , filtered, washed with water, EtOH and  $\text{Et}_2\text{O}$  and the residue dried *in vacuo* over  $\text{H}_2\text{SO}_4$ , yields the compd.  $\text{C}_{26}\text{H}_{22}\text{N}_4\text{S}$ , decomp. without fusion, probably has the constitution:  $[\text{H}_2\text{NC}_6\text{H}_4\text{C}_6\text{H}_4\text{NHCS-}]_2$ . It contains 2 free  $\text{NH}_2$  groups, for, diazotized and coupled with alk.  $\beta$ -naphthol, it gave the compd.  $\text{C}_{46}\text{H}_{40}\text{O}_2\text{N}_4\text{S}$ , dark red, decomp. above  $210^\circ$  without fusion, gives a violet-red soln. in concd.  $\text{H}_2\text{SO}_4$ ; its structure is probably  $[\beta\text{-HOC}_6\text{H}_4\text{N-NC}_6\text{H}_4\text{C}_6\text{H}_4\text{NHCS-}]_2$ . The expts. are being continued.

C. C. DAVIS

**Thioureas in the series of azo derivatives.** G. B. CRIPPA (WITH G. FAINI). *Gazz. chim. ital.* 58, 726-31(1928).—Though there is an extensive literature on the phenyl- and naphthylthioureas derived from aromatic amines, there are only 2 references to

thioureas from azo compds. (cf. Berju, *Ber.* 17, 1404(1884); Bolser and Hartshorn, *C. A.* 17, 3863). This lack of data induced C. to prep. several thioureas of azo compds. by the action of CS<sub>2</sub> on aminoazo compds. Cold CS<sub>2</sub> (60 cc.) added to *p*-H<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>N<sub>2</sub>Ph (6 g.) in EtOH (90 cc.), boiled for 15 hrs., filtered, washed with EtOH and Et<sub>2</sub>O and the residue recrystd. from PhNO<sub>2</sub>, yields (*p*-PhN<sub>2</sub>C<sub>6</sub>H<sub>4</sub>NH)<sub>2</sub>CS (I), m. 202° (cf. Berju, *loc. cit.*), decomps. above its m. p. with evolution of yellow fumes with a characteristic odor. The ease of formation of I is an indirect confirmation of the conclusions of Bolser and Hartshorn (*loc. cit.*) regarding the condensation products of *p*-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub> and CS<sub>2</sub>. Let stand at room temp. with a mixt. of AcOH and perhydrol, filtered, the residue extd. with xylene and the ext. evapd., I yields (*p*-PhN<sub>2</sub>C<sub>6</sub>H<sub>4</sub>NH)<sub>2</sub>CO. The latter is also formed when I is oxidized by yellow HgO in boiling EtOH. When the oxidation with perhydrol is carried out above room temp., a brown substance is formed which contains no S and which is probably a carbamidoazoxy deriv. I (15 g.) suspended in hot AcOH, reduced with Zn dust (40 g.), boiled 1 hr., neutralized with satd. Na<sub>2</sub>CO<sub>3</sub>, filtered, the residue dried, ext. with EtOH, the ext. concd., dild. with water and the ppt. recrystd. from dil. EtOH, gives a very small yield of (*p*-H<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>NH)<sub>2</sub>CS. The latter in EtOH boiled with CS<sub>2</sub> for 12 hrs., the condensation product treated with cold dil. HCl, then with boiling EtOH, filtered and washed with boiling water, yields diphenylenedithiourea. Since the latter is also formed by condensation from *p*-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub> and CS<sub>2</sub>, it has a dimeric *p*-cyclic structure and not the monomeric type of phenylenedithiourea. Following the same procedure as for I, there was prepd. 4,4'-thiocarbamido-1,1'-phenylazonaphthalene, yellow, m. 165°. Boiled for a long time with AcOH it forms phenylazo- $\beta$ -naphthylamine and an unidentified green compd. contg. S. Likewise from *o*-, *m*- and *p*-tolylazo-4-naphthalene were prepd.: 4,4'-thiocarbamido-1,1'-*o*-tolylazonaphthalene, m. 160°; 4,4'-thiocarbamido-1,1'-*m*-tolylazonaphthalene, m. 172°, and 4,4'-thiocarbamido-1,1'-*p*-tolylazonaphthalene, m. 185°. The last, treated for a long time with AcOH at 60–70°, yields a small quantity of a dark yellow substance, contg. no S, m. 215°. CS<sub>2</sub> reacts extremely slowly with *o*-H<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>N<sub>2</sub>Ph, and an appreciable quantity of the condensation product can be obtained only after boiling about 100 hrs. This product is brown, m. 100°, and by analogy should be 2,2'-thiocarbamidoazobenzene. Likewise CS<sub>2</sub>, boiled for a long time with alc. phenylazo- $\beta$ -naphthylamine, forms a brown substance which by analogy should be 2,2'-thiocarbamido-1,1'-phenylazonaphthalene. These compds. are to be studied further.

C. C. DAVIS

Phenyl isothiocyanate and *o*-tolyl isothiocyanate as reagents for primary aromatic bases. THEO. OTTERBACHER and FRANK C. WHITMORE. *J. Am. Chem. Soc.* 51, 1909–11 (1929).—PhNCS and *o*-MeC<sub>6</sub>H<sub>4</sub>NCS are satisfactory reagents for many primary aromatic amines, forming well crystg. and sharply melting thiocarbamides in good yields. The reagents do not react with H<sub>2</sub>O or EtOH and a detn. may be made in their presence. There are no by-products of the reaction. The following m. ps. are for the *o*-MeC<sub>6</sub>H<sub>4</sub>NCS and PhNCS derivs., resp.: *p*-MeC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>, 132°, 141°; *o*-MeC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>, 158°, 136°; *m*-MeC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>, 140°, 94°; *p*-BrC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>, 143°, 148°; *o*-BrC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>, 128°, 146°; *m*-BrC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>, 101°, 97°; *p*-ClC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>, 134.5°, 152°; *o*-ClC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>, 140°, 156°; *m*-ClC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>, 124°, 116°; *p*-IC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>, 150°, 153°; PhNHNH<sub>2</sub>, —, 172°; (PhNH)<sub>2</sub>, —, 168°; 3,4-Br(H<sub>2</sub>N)C<sub>6</sub>H<sub>3</sub>Me, 132°, 154.5°; 2,4-Me<sub>2</sub>C<sub>6</sub>H<sub>3</sub>NH<sub>2</sub>, 143.5°, 133.5°; 2,5-H<sub>2</sub>N(HO)C<sub>6</sub>H<sub>3</sub>Me, 182.5°, 167.5°; *p*-H<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>OH, 158°, 150°; NH<sub>3</sub>, 160°, 154°; *p*-MeOC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>, 138°, —; *o*-MeOC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>, 126°, —.

C. J. WEST

Nitration of phenylbenzylamine derivatives. JOSEPH REILLY, PETER J. DRUMM and TIMOTHY V. CREEDON. *J. Chem. Soc.* 1929, 641–4.—In a previous paper (cf. *C. A.* 22, 1963) the authors showed that on nitration of PhNHCH<sub>2</sub>Ph and PhN(CH<sub>2</sub>Ph)<sub>2</sub> under similar conditions the former yielded only the nitrate of the base. Nitration of the secondary base in H<sub>2</sub>SO<sub>4</sub> led to the formation of 3-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>CH<sub>2</sub>NHPh together with a smaller amt. of the corresponding 4-nitro deriv. The work is now extended to include the nitration of PhNHCH<sub>2</sub>Ph derivs. in which the NH-H is replaced by acidic and other groups. Unlike the parent substance, PhN(NO)CH<sub>2</sub>Ph is nitrated directly or in AcOH soln. with remarkable ease giving 4-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>N(NO)CH<sub>2</sub>Ph as the main product and a small amt. of the 2-nitro compd. In the nitration of PhN(CH<sub>2</sub>Ph)<sub>2</sub> in H<sub>2</sub>SO<sub>4</sub> the authors have isolated a new dinitro deriv. which is shown by direct synthesis to be phenyldi-*m*-nitrodibenzylamine, canary-yellow, m. 129–30°. The exptl. evidence supports the view that nitration of PhNHCH<sub>2</sub>Ph derivs. directly (*i. e.*, as bases) leads to the formation of nitro derivs. substituted in the aniline ring, whereas nitration through the salt promotes substitution in the benzyl nucleus. W. O. EMERY

Attempts to synthesize *o*-thiolphenylhydrazine. PRAPHULLA CHANDRA GUHA

AND TEJENDRA NATH GHOSH. *J. Indian Inst. Sci.* 12A, 31-5(1929).—*o*-HSC<sub>6</sub>H<sub>4</sub>NHNH<sub>2</sub> (I) cannot be prepd. from *o*-HSC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub> by diazotization and subsequent reduction. Hence (*o*-H<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>S)<sub>2</sub> (II) was (in 35% yield) prepd. by Hofmann's method (*Ber.* 20, 2259) (except that the final oxidation was carried out with I<sub>2</sub> soln.), and was diazotized. Its diazonium salt, however, could not be reduced with SnCl<sub>2</sub> and HCl or with Na<sub>2</sub>SO<sub>3</sub> to I, and it could not be coupled with aniline or EtOCS<sub>2</sub>K, but decompd. always to give a brownish tar, which on steam distn. yielded a pale yellow oil, (III), C<sub>13</sub>H<sub>8</sub>OS<sub>2</sub>, b. 231° (decompn.). III is evidently *oxydiphenylene disulfide*,

*o*-C<sub>6</sub>H<sub>4</sub>.SS.C<sub>6</sub>H<sub>4</sub>.O, formed by loss of water from the unstable (*o*-HOC<sub>6</sub>H<sub>4</sub>S)<sub>2</sub>. 37 g. III was obtained from II (10 g.) by diazotization and decompn. on standing in water. This is the first synthesis of a 7-membered ring contg. 1 O and 2 S. Reduction of III with Sn and HCl gave a colorless oil, probably a mercaptan. (*o*-AcNH(C<sub>6</sub>H<sub>4</sub>S)<sub>2</sub> (IV) (3 g.), m. 154°, was prepd. by refluxing II (3 g.) with Ac<sub>2</sub>O (10 cc.) and fused AcONa (1.5 g.) 2-3 mins. G. and G. hoped to make the NO deriv., [*o*-AcN(NO).C<sub>6</sub>H<sub>4</sub>S]<sub>2</sub> (V) and then I by reduction. V could not be obtained by addn. of NaNO<sub>2</sub> (1 g.) to IV (2 g.) in moderately strong HCl; or by passing the gas from strong HNO<sub>3</sub> and As<sub>2</sub>O<sub>3</sub> into IV in HCl or in glacial AcOH (the hot soln. in AcOH was rapidly cooled in ice to a crystn. paste). Just as benzenyl-*o*-aminothiophenol (VI) gives *o*-HSC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub> when heated with fused potash (*Ann.* 208, 291; *Ber.* 13, 1223; 20, 2259), G. and G.

hoped that 2,3-benzo-6-phenyl-1,4,5-thiodiazine, C<sub>6</sub>H<sub>4</sub>.S.CPh.N.NH (VII), might give I. VIII, yellowish plates, m. 109° (5.6 g.), was prepd. from PhNHNHBr (80 g.) and S (30 g.) at 190-200° for 24 hrs. (cf. Hofmann, *Ber.* 13, 1223, for the prepn. of VI, which G. and G. prepd. in 50% yield). VII (20 g.) fused with powd. KOH (100 g.) gave BzOH and H<sub>2</sub>S, but no compd. with the SH or NHNH<sub>2</sub> group. J. D. S.

Cyclic *N*-hydroxy and *N*-oxide compounds. GUSTAV HELLER. *J. prakt. Chem.* [2], 121, 269-72(1929).—In the reduction of certain *o*-nitro substituted derivs. of PhH, *N*-HO compds. are formed; in other cases, *N*-oxide derivs. result. H. reviews the literature and concludes that in some cases there is a question as to whether the product belongs to the *N*-HO or *N*-oxide series. He suggests various tests by which this may be detd. M. A. DAILEY.

10-Chloro-5,10-dihydrophenarsazine and its derivatives. VII. Synthesis of the 1-methyl and 3-methyl homologs. CHARLES S. GIBSON AND JOHN D. A. JOHNSON. *J. Chem. Soc.* 1929, 767-87; cf. *C. A.* 22, 4528.—3-Amino-*p*-tolylarsonic acid (I) (10 g.) was dissolved in 18.7 cc. of HCl and 16.5 cc. of H<sub>2</sub>O and diazotized with 3.33 g. of NaNO<sub>2</sub> in 6.6 cc. of H<sub>2</sub>O (below 0°). This was added to 3.8 g. of CuCl<sub>2</sub> in 12.7 cc. of HCl during 3 mins., followed by 25 cc. of H<sub>2</sub>O. After stirring for 30 mins., filtering, washing with cold H<sub>2</sub>O and recrystg. from hot H<sub>2</sub>O, 65% of 3-chloro-*p*-tolylarsonic acid (II), m. 189-91°, was obtained. II (4.3 g.) was dissolved in 14 cc. of HCl contg. a trace of I and treated with SO<sub>2</sub> for 5 mins. After cooling, the oil was extd. in PhH, dried over CaCl<sub>2</sub>, evapd. and finally distd. *in vacuo*, giving 3-chloro-*p*-tolylidichloroarsene (III), b<sub>17</sub> 166-7°, m. 27-9°. One g. of III was warmed with 5 cc. of H<sub>2</sub>O and 5 cc. of NH<sub>4</sub>OH soln. (d. 0.88) for 20 mins., filtered, washed with H<sub>2</sub>O and repptd. from NaOH by means of CO<sub>2</sub>, giving 3-chloro-*p*-tolylarsenious oxide, m. 277°. Treatment of the diazo soln. of I with HBr and Cu<sub>2</sub>Br<sub>2</sub> (from CuSO<sub>4</sub> + KBr satd. with SO<sub>2</sub>), gave, instead of II, the 3-Br deriv. 4,2-MeBrC<sub>6</sub>H<sub>3</sub>AsO<sub>2</sub>H<sub>2</sub> (IV), m. 208-10° (decompn.) (72% yield). In the same manner as III, 60% of the 3-Br analog (V), b<sub>14</sub> 176-7°, m. 47-9°, was obtained and subsequently 3-bromo-*p*-tolylarsenious oxide, m. 266-8°. A warm soln. of 5 g. of II in 20 cc. of H<sub>2</sub>O contg. 5.7 g. of Na<sub>2</sub>CO<sub>3</sub>.10H<sub>2</sub>O was added to 12.6 g. of KMnO<sub>4</sub> in 312 cc. of H<sub>2</sub>O and boiled for 8 hrs. while continuously subjected to a stream of CO<sub>2</sub> bubbles. After cooled, acidified

acid (VI), m. over 310°. In the same manner, 65% of the 2-Br analog of IV was obtained. A mixt. of 11.8 g. of IV, 3.75 g. of PhNH<sub>2</sub>, 8.8 g. of anhyd. K<sub>2</sub>CO<sub>3</sub>, 35 cc. of AmOH and a trace of Cu powder was boiled for 5 hrs., steam distd., decolorized, filtered and acidified with dil. HCl, giving 63% of crude 3-methyldiphenylamine-6-arsonic acid, 4,2-Me(PhNH)C<sub>6</sub>H<sub>3</sub>AsO<sub>2</sub>H<sub>2</sub> (VII). Pure VII, m. 158-9° (sol. in HOAc, MeOH, EtOH and Me<sub>2</sub>CO), was obtained by mixing the crude with cold NH<sub>4</sub>OH, warming to soln., then adding concd. NH<sub>4</sub>OH; the NH<sub>4</sub> salt which crystd. was dissolved in H<sub>2</sub>O, acidified with HCl and the ppt. decolorized in HOAc to which enough water had been added while boiling to cause turbidity; cooling after filtration pptd. VII. VII (3.45 g.) was dissolved in 15 cc. of hot HCl and 15 cc. of EtOH contg. a trace of I, reduced with SO<sub>2</sub>, cooled and the 2.2 g. of ppt. was dried and recrystd. from PhH, giving yellow

10-chloro-3-methyl-5,10-dihydrophenarsazine (VIII), m. 216–6.5°. Two g. of VIII, dissolved in 70 cc. Me<sub>2</sub>CO, was treated with 4.5 g. chloramine-T in 63 cc. of H<sub>2</sub>O; after 30 mins. 81% of 3-methylphenarsazinic acid (IX) was filtered off and recrystd. from HOAc which gave IX + HOAc which was not removed by drying over KOH. Two g. of VIII was also oxidized in boiling HOAc (20 cc.) with 4.0 cc. of H<sub>2</sub>O<sub>2</sub>; 80 cc. of H<sub>2</sub>O was added, the solid filtered off, dissolved in hot NaOH and decolorized with charcoal. Excess NaOH was added and, upon cooling, 79% of IX pptd. as the Na salt which was dissolved in warm water and acidified, pptg. IX. Upon cooling a soln. of 1.6 g. of IX in 47 cc. of hot EtOH and 14 cc. of HCl, the HCl salt, m. 232–3° (decompn.), was pptd.; this is also obtained by boiling IX with concd. HCl, cooling, filtering and recrystg. from EtOH and HCl. Through the use of HBr instead of HCl in the prepn. of VIII, the 10-Br deriv. (X), m. 206–8°, was obtained. Yellow 3-nitro-*p*-tolyl-dichloroarsine, m. 113°, was prepd. from the arsonic acid in the same manner as III. 3-Nitro-*o*-tolyl-arsonic acid (XI), m. 228–30°, was prepd. according to Jacobs, Heidelberger and Rolf (C. A. 12, 2550); it was found that excess HOAc added to the "coupled" soln. before the addn. of HCl gave the Na H salt of XI, m. 97°; soln. of this in NaOH and pptn. with mineral acid gave XI. XI was converted into 3-nitro-*o*-tolyl-dichloroarsine (XII), m. 93°, by the method used to prep. III. Boiling 12.2 g. of XI with 100 cc. of HBr (d 1.49) contg. a trace of I gave 92% of yellow dibromoarsine deriv., m. 116.5–7.5°. 3-Amino-*o*-tolylarsonic acid was prepd. according to the method of J. H. and R., evapg. the aq. soln. of the Na salt under reduced pressure to avoid excessive dearsenication; 12 g. of this was dissolved in 22.4 cc. HCl and 20 cc. of H<sub>2</sub>O and converted to 76% of the 3-Cl-*o*-deriv., m. 236–9° (decompn.), in the manner used to prep. II, which was converted to 78% of the dichloroarsine (XIII), b<sub>11</sub> 156°, m. 37.5°, by the method used for III. Heating XIII with NH<sub>4</sub>OH gave the arsenious oxide, m. to a milky liquid at 234–7°. The 3-bromo-*o*-tolyl derivs. were prepd. in the same general manner as IV, V, etc., giving 75% of the arsonic acid, 2,6-MeBrC<sub>6</sub>H<sub>3</sub>AsO<sub>3</sub>H<sub>2</sub> (XIV), m. over 306°; the dichloroarsine, b<sub>13</sub> 170–1°, m. 25–7°; and the arsenious oxide, m. 214–9°. XIV was converted to 67% of 3-methyldiphenylamine-2-arsonic acid (XV), m. 170–1° (decompn.), and subsequently to 10-chloro-1-methyl-5,10-dihydrophenarsazine (XVI), m. 216–6.5°, and 1-methylphenarsazinic acid (XVII), m. 316° (decompn.), by the method for the 3-Me isomers VII, VIII and IX. Boiling 1.1 g. of XV with concd. HCl (8 cc.), adding 8 cc. of EtOH and cooling gave the HCl deriv., m. 231–2° (decompn.); this was also prepd. from XVII by boiling with a mixt. of EtOH and HCl. Boiling 21 g. of *o*-bromophenylarsonic acid (XVIII), 8 g. of *m*-MeC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>, 65 cc. of AmOH and 16.3 g. of anhyd. K<sub>2</sub>CO<sub>3</sub> with a trace of Cu powder for 5 hrs. gave 61% of 3-methyldiphenylamine-6'-arsonic acid (XIX), m. 141–2°, which was worked up in the same manner as VII and reduced to 1- and/or 3-methyl-10-chloro-5,10-dihydrophenarsazine (XX), m. 216–7°. This substance was oxidized by both methods given for VIII and the product (XXI) was indistinguishable from the rationally synthesized 1-methyl- and 3-methylphenarsazinic acids. Treating XIX as in the case of VII and XV, the HCl deriv., m. 232–3°, was indistinguishable from IX or XVII. There exists a possibility that IX, XVII and the HCl deriv. of XXI are the same, but it would require a ring-splitting and rearrangement of XVI during its conversion to XVII.

A. S. CARTER

Reaction of mercuric acetate with *p*-bromodiethylaniline. FRANK C. WHITMORE, A. R. CADE AND G. J. LEUCK. *J. Am. Chem. Soc.* 51, 1952(1929).—While *p*-BrC<sub>6</sub>H<sub>4</sub>NMe<sub>2</sub> gives a good yield of *o*-Hg product, *p*-BrC<sub>6</sub>H<sub>4</sub>NEt<sub>2</sub> does not react with Hg(OAc)<sub>2</sub> under any of the exptl. conditions tried, except to give unmanageable oxidation products.

C. J. WEST

Tin tetraphenyl as a phenylating reagent. R. W. BOST AND P. BORGSTROM. *J. Am. Chem. Soc.* 51, 1922–5(1929).—SnPh<sub>4</sub> reacts with halogens to form aryl monohalides, with acyl halides to form Ph ketones, with S to form Ph<sub>2</sub>S, Ph<sub>2</sub>S<sub>2</sub> and thianthrene. The reactions with alkyl halides and SO<sub>2</sub>Cl<sub>2</sub> were not conclusive. With HNO<sub>3</sub>, PhNO<sub>2</sub> was isolated.

C. J. WEST

The formation of a closed heterocyclic ring by mercury atoms. L. VECCHIOTTI. *Gazz. chim. ital.* 58, 712–5(1928).—A preliminary note. Expts. by Dreher and Otto (Ann. 154, 93), by Pesci (*Gazz. chim. ital.* 28, ii, 101) and by V. in his numerous researches (C. A. 21, 395; 22, 231, 2555, 4506, 4507) have shown that aromatic groups may be linked together by a bridge of a single Hg atom. It was of interest to det.

whether by carrying out similar reactions with compds. contg. 2 AcOHg groups it would be possible to synthesize compds. of the general formula  $R \begin{array}{c} \text{Hg} \\ \diagup \quad \diagdown \\ \text{Hg} \end{array} R$ . The initial expts. were carried out with  $\alpha$ - and with  $\beta$ -biacetatomercuri-*o*-chloroaniline and seemed to indicate the formation of compds. contg. 2 Hg bridges, as already described (cf. V. and Michetti, *C. A.* 20, 589). Continuing the expts., diacetatomercurianiline (cf. V., *C. A.* 9, 448) and 50%  $\text{Na}_2\text{S}_2\text{O}_4$  heated several hrs. yielded a white, semi-gelatinous substance, which showed evidence of decompn. at  $162^\circ$  and m.  $184^\circ$ , and which was insol. in all solvents. Its constitution was probably one of the 2 following structures:

Expts. are in progress dealing with the action of Na-Hg on compds. formed from halogenated  $\text{C}_6\text{H}_4$  nucleus and contg. a lateral chain halogenated at its extremity.

C. C. DAVIS

**Trypanocidal activity and chemical constitution. I. New sulfur derivatives of aromatic organic arsenicals.** JOHN G. EVERETT. *J. Chem. Soc.* 1929, 670-9.—Aromatic org. arsenicals contg. the C:S group attached to N have been prepd. and tested in exptl. infections of *Trypanosoma equiperdum* in mice. Results show that the permanency of cure and the toxicity are not influenced appreciably by the substitution of S for O, except in those compds. contg. As in the 5-position in a 2-thiolbenzimidazole ring, which are very efficacious. Aminophenylarsonic acids have been condensed with  $\text{CS}_2$  in the presence of alc. and NaOH by boiling. From *p*-arsanilic acid 70% of *p,p'*-dithiocarbiminophenylarsonic sesquisulfide (I) instead of the expected *diphenylthiourea-p,p'*-arsenic sesquisulfide (II) was obtained as a yellow amorphous solid. The constitution of I was shown as follows: Hydrolysis with NaOH gave II. Reduction with  $\text{Na}_2\text{S}_2\text{O}_4$  gave 74% *p,p'*-dithiocarbiminoarsenobenzene (III). Hydrolysis of III by NaOH gave 81% of *p,p'*-arseno[*diphenylthiourea*] (IV), obtained also as an orange amorphous solid by reduction and hydrolysis of I with  $\text{Na}_2\text{S}_2\text{O}_4$  and 25% NaOH at  $90^\circ$  (yield 40%), by reduction of II with  $\text{Na}_2\text{S}_2\text{O}_4$  (yield 62%), and by the reduction of *diphenylthiourea-p,p'*-diarsonic acid (V) with  $\text{Na}_2\text{S}_2\text{O}_4$  (yield 71%). From  $\text{CSCl}_2$  and *p*-arsanilic acid in NaOH, V can be obtained in 69% yield and also by treating IV and II, resp., with 0.1 N I, in yields of 42% and 31%. In the presence of excess  $\text{NaHCO}_3$  followed by treatment with 0.5 N I, V gave 43% *diphenylurea-p,p'*-diarsonic acid (VI), identical with the compd. from  $\text{COCl}_2$  and *p*-arsanilic acid. These reactions are summarized as follows:

From 4,3-HO(H<sub>2</sub>N)C<sub>6</sub>H<sub>3</sub>AsO<sub>2</sub>H<sub>2</sub> condensed similarly to *p*-arsanilic acid, 64% of 1-thio-benzoxazolone-4-arsenic disulfide (VII), sol. in dil. NaCN, was obtained. Reduction of VII and IX, resp., with  $\text{Na}_2\text{S}_2\text{O}_4$  gave 4,4'-arseno[1-thiobenzoxazolone] (VIII), a yellow amorphous solid sol. in dil. NaCN, in yields of 73% and 70%. On treatment with I, both VII and VIII gave 30% and 45%, resp., of 1-thiobenzoxazolone-4-arsenic acid (IX), yellow needles, identical with that obtained from 4,3-HO(H<sub>2</sub>N)C<sub>6</sub>H<sub>3</sub>AsO<sub>2</sub>H<sub>2</sub> and  $\text{CSCl}_2$ , in 78% yield. In the presence of excess  $\text{NaHCO}_3$  and treatment with I, IX gave 77% of benzoxazolone-4-arsenic acid (X) identical with the compd. from  $\text{COCl}_2$  and 4,3-HO(H<sub>2</sub>N)C<sub>6</sub>H<sub>3</sub>AsO<sub>2</sub>H<sub>2</sub>.

From 3,4-(H<sub>3</sub>N)<sub>2</sub>C<sub>6</sub>H<sub>4</sub>AsO<sub>2</sub>H<sub>2</sub>, 64% of 2-thiolbenzimidazole-5-arsenic disulfide (XI) was obtained, which when reduced by Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub> gave 72% 5,5'-arseno[2-thiolbenzimidazole] (XII). On oxidizing with I, 2-thiolbenzimidazole-5-arsonic acid (XIII), obtained from XI by treatment with I (yield 37%), gave benzimidazole-5-arsonic acid (XIV) in 83% yield. (H<sub>3</sub>N)<sub>2</sub>C<sub>6</sub>H<sub>4</sub>AsO<sub>2</sub>H<sub>2</sub> →

S attached to As only may be sharply differentiated from mercaptan S, by means of either I or Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub>, the latter form not being oxidized by I unless some alkali is present. The arsenic acids V, IX and XIII gave no color with alk. Na<sub>2</sub>Fe(CN)<sub>5</sub>NO soln. whereas all sulfides mentioned gave a deep violet color. In order to compare O with S, in analogous compds., VI and X and their arseno compds. were prepd. In many cases due to the amorphous nature of the compds. the at. ratios of As:N:S were found for the purpose of identification.

**The thermal behavior of phenols.** A. HAGEMANN. *Z. angew. Chem.* 42, 355-61 (1929).—When PhOH vapor is passed through a tube filled with pumice stone and heated to 650-750°, it decomps. as follows: PhOH = CO + H + "balance of mol."; the removal of the CO group destroys the aromatic character and structure, thus necessitating a rearrangement of the "balance of the mol." into a more stable form resulting in the formation of (a) C + H; (b) partial hydrogenation by the liberated H to form CH<sub>4</sub>, C<sub>2</sub>H<sub>4</sub>, (CH<sub>2</sub>:CH)<sub>2</sub>; (c) traces of C<sub>2</sub>H<sub>2</sub>; (d) condensation of the CH≡ fragments to form aromatic hydrocarbons such as PhH, C<sub>10</sub>H<sub>8</sub>, C<sub>14</sub>H<sub>10</sub>, phenanthrene and chrysene. Under similar conditions at a temp. of 850° PhOH decomps. as follows: PhOH = H<sub>2</sub>O + "balance of mol."; again the unstable "balance of mol." is immediately converted into the more stable forms as above. The decompn. of PhOH in all cases causes a rupture of the ring. The formation of PhH is due to a subsequent polymerization of the CH≡ fragments. Decompn. of PhOH at 300-450° in contact with Ni catalyst on silica gel is as follows: PhOH = CO + 3H<sub>2</sub> + 5C; the CO thus formed is partly decomd. into CO<sub>2</sub> + C, while a part of the H reduces the intermediate CH≡ fragments to CH<sub>4</sub>. Similarly, in contact with activated charcoal the principal reaction is: PhOH = H<sub>2</sub>O + 2H<sub>2</sub> + 6C with a small portion reacting as follows: PhOH = CO + 3H<sub>2</sub> + 5C; at the same time reduction takes place as follows: PhOH = H<sub>2</sub> + C<sub>6</sub>H<sub>6</sub> + H<sub>2</sub>O; the amt. of aromatic condensation products is very small. When *m*-cresol and N<sub>2</sub> are passed through an unfilled hot tube at 630-50°, decompn. occurs as follows: MeC<sub>6</sub>H<sub>4</sub>OH = CO + H + "balance of mol."; under the influence of H, the "balance of mol." loses the Me with formation of CH<sub>4</sub>, H<sub>2</sub> and polymerization of CH≡ fragments to aromatic hydrocarbons as PhH, C<sub>10</sub>H<sub>8</sub>, etc.; a part of the "balance of mol." retains the Me and polymerizes to methylated hydrocarbons, MePh, MeC<sub>10</sub>H<sub>7</sub>, etc.; simultaneously part of the H gives rise to the following reactions: MeC<sub>6</sub>H<sub>4</sub>OH + 2H = MeH + PhOH. The % yields of compds. obtained at 750° are given in detail. The expts. with dihydroxybenzenes were conducted by passing the vapors through a quartz tube filled with glass rings. *o*-C<sub>6</sub>H<sub>4</sub>(OH)<sub>2</sub> decompd. as follows: C<sub>6</sub>H<sub>4</sub>(OH)<sub>2</sub> = (2CO + 2H + "balance of mol.") = (CH<sub>2</sub>:CH)<sub>2</sub> + 2CO; the yield of butadiene was 21%; the decompn. of hydroquinone was similar. The decompn. of resorcinol is as follows: C<sub>6</sub>H<sub>4</sub>(OH)<sub>2</sub> = (2CO + 2H + "balance of mol.") = (CH<sub>2</sub>:CH)<sub>2</sub>, C<sub>2</sub>H<sub>4</sub>, CH<sub>4</sub>, C, H and aromatic hydrocarbons; the yield of (CH<sub>2</sub>:CH)<sub>2</sub> was low. When phloroglucinol is heated in a flask (with O<sub>2</sub> excluded), it first decomps. as follows: 2C<sub>6</sub>H<sub>3</sub>(OH)<sub>3</sub> = H<sub>2</sub>O + (HO)<sub>2</sub>C<sub>6</sub>H<sub>2</sub>OC<sub>6</sub>H<sub>2</sub>(OH)<sub>2</sub>; when the temp. is raised to 320-50°, a gas is rapidly evolved consisting of 98.8% CO<sub>2</sub> and the balance CO, H, CH<sub>4</sub> and other hydrocarbons; the residue is about 80% sol. in Me<sub>2</sub>CO and seems to resemble a humic acid. When α-naphthol is heated to 600° in a glass tube, it decomps. into CO, H and "balance of mol." the latter subsequently decompd. into C and H which then reduce the unchanged α-naphthol to C<sub>10</sub>H<sub>8</sub>, CH<sub>4</sub>, a hydrocarbon C<sub>22</sub>H<sub>10</sub> of unknown constitution and possibly some α-dinaphthylene oxide. The decompn. of β-naphthol is similar except that the "balance of mol." decomps. into PhH, PhMe, C<sub>7</sub>H<sub>8</sub> gases, C<sub>10</sub>H<sub>8</sub>, β-dinaphthostilbene and methylenedinaphthyl oxide, C<sub>10</sub>H<sub>4</sub>.CH<sub>2</sub>.C<sub>10</sub>H<sub>4</sub>.O.

N. A. LANGE

**Action of bromine on certain mixed ethers.** L. CHAS. RAIFORD AND D. M. BIROSEL. *J. Am. Chem. Soc.* 51, 1776-8(1929).—Ph allyl ether and Br in CHCl<sub>3</sub> give 2,4,6-Br-

$C_6H_5OH$  and 2,4-dibromophenyl  $\beta,\gamma$ -dibromopropyl ether,  $b_{10}$  220–3°. 2,4- $Br_2C_6H_3OH$ , by Claisen's method, gives 54% of 2,4-dibromophenyl allyl ether,  $b_{12-23}$  165–70°. 5-Tribromophenyl allyl ether and Br in  $CHCl_3$  give 2,4,6-tribromophenyl  $\beta,\gamma$ -dibromopropyl ether, m. 42.5–3.5°. 2-Nitro-4-chlorophenyl deriv., m. 55°; 2,4,6-trinitrophenyl deriv., m. 102°. 2,4- $Br_2C_6H_3OH$  and iso-PrOH give 2,4-dibromophenyl isopropyl ether,  $b_{11}$  156°; 2,4,6-tribromophenyl deriv., m. 40°. The HBr evolved in the bromination of the ethers tested may split them unless  $AcONa$  is present. The splitting is most pronounced when the alkyl is connected through a sec. or tert. C atom. C. J. W.

Oxidation-reduction. XIII. Preparation of indophenols which may be used as oxidation-reduction indicators. H. D. GIBBS, W. L. HALL and W. M. CLARK. *U. S. Pub. Health Repts. Suppl.* No. 69, 35 pp. (1929).—For the group  $H_2:C_6H_4:O$  the name of "benzenone" is retained when the two H atoms are substituted by :N-, while for this bridging N the stem "ind." is used. The nomenclature of the compds. is discussed. The prepn. by oxidation of a mixt. of a phenol and a  $p$ -aminophenol by  $NaOCl$  gives poor results as a lab. method. The reported substances are prepd. by the action of  $NaOCl$  on an aminophenol and coupling the formed quinonechloroimide with the phenol by adding  $NaOH$ ; the Na salt is salted out. Leucoindophenols are obtained by reducing the Na salts with  $K_2S$  and pptg. with  $AcOH$ . Benzenoneindophenol ( $p$ -indophenol) was obtained from the Na salt by pptg. with  $CO_2$ . It has no definite m. p. At 129° an exothermic reaction takes place. Leuco- $p$ -indophenol, m. 175.5°. 2-Methylbenzenoneindophenol (*o*-cresolindophenol),  $O:C_6H_3(CH_3):NC_6H_4OH$ . Two samples prepd. by both methods gave at  $p_H$  8.633  $E'_{0.0846}$  and 0.0844; calcd. 0.0851. At  $p_H$  9.609  $E'_{0.0108}$  and 0.0167; calcd. 0.0113. M. p. 162°. The leuco-2-methylindophenol (4,4'-dihydroxy-3-methyldiphenylamine) shrinks at 151°, m. 152.5°. 3-Methylbenzenoneindophenol (*m*-cresolindophenol), m. 110–1° (decompn.). The leuco compd. could not be isolated. 2,6-Dimethylbenzenoneindophenol,  $O:C_6H_3(CH_3)_2:NC_6H_4OH$  from buinonechloroimide and 2,6- $Me_2C_6H_3OH$ . The Na salt forms green crystals. 3-Methyl-6-isopropylbenzenoneindophenol (thymolindophenol), m. 134.1°, at 151° decompn. sets in. 2-Methyl-5-isopropylbenzenoneindophenol (carvacrolindophenol), m. 121.2° and is stable up to 171°. 2-Methoxybenzenoneindophenol (guaiacolindophenol), m. 171°. 3-Methoxybenzenoneindophenol (methylresorcinolindophenol) is sol. in  $Et_2O$  to 0.5% and can be pptd. from this soln. with benzine. 2-Chlorobenzenoneindophenol (*o*-chlorophenolindophenol) was not obtained in a pure form. 2-Bromobenzenoneindophenol (*o*-bromophenolindophenol) The Na salt, when heated, carbonized below 100°, the free indophenol was not obtained, the leuco compd. not in cryst. form. 3-Bromobenzenoneindophenol (*m*-bromophenolindophenol) was obtained as the Na salt in a very impure form. 2,6-Dichlorobenzenoneindophenol (2,6-dichlorophenolindophenol). The Na salt is nearly insol. in  $H_2O$ . The leuco compd. m. 175°. 2,6-Dichlorobenzenoneindo-3'-methylphenol (2,6-dichlorophenolindo-*o*-cresol),  $O:C_6H_3Cl_2:NC_6H_4MeOH$  from 2,6-dichloroquinonechloroimide and *o*-cresol. The leuco compd., when recrystd. from 20%  $EtOH$  in  $H_2O$ , m. 108°. On drying at 90° 1 mol.  $H_2O$  is lost. The m. p. is then 114°. 2,6-Dichlorobenzenoneindo-2'-methylphenol (2,6-dichlorophenolindo-*m*-cresol); the leuco compd., m. 209°, when crystd. from  $MeOH$ . 2,6-Dichlorobenzenoneindo-3'-chlorophenol (2,6-dichloroindo-*o*-chlorophenol); the Na salt is green, purple by transmitted light. No leuco compd. was prepd. 2,6-Dichlorobenzenoneindo-2'-chlorophenol (2,6-dichlorophenolindo-*m*-chlorophenol) was obtained as the Na salt only of 85.2% purity. 2,6-Dibromobenzenoneindophenol (2,6-dibromophenolindophenol); the leuco compd. was recrystd. from 20%  $MeOH$  and m. 179–81°. 2,6-Dibromobenzenoneindo-3'-methylphenol (2,6-dibromophenolindo-*o*-cresol); the Na salt was dissolved in  $EtOH$  and pptd. with  $Et_2O$ . 2,6-Dibromobenzenoneindo-2'-methylphenol (2,6-dibromophenolindo-*m*-cresol). 2,6-Dibromobenzenoneindo-2'-methyl-5'-isopropylphenol (2,6-dibromophenolindothymol), from 2,6-dibromoquinonechloroimide and thymol. 2,6-Dibromobenzenone-3'-methoxyphenol (2,6-dibromophenolindo-*o*-guaiacol). 2,6-Dibromobenzenoneindo-3'-bromophenol (2,6-dibromoindo-*o*-bromophenol). 2,6-Dibromobenzenoneindo-2'-bromophenol (2,6-dibromoindo-*m*-bromophenol). 2,6-Dibromobenzenoneindo-3'-chlorophenol (2,6-dibromophenolindo-*o*-chlorophenol). 2,6-Dibromobenzenoneindo-3'-Na sulfonatephenol (2,6-dibromophenolindo-*o*-phenol - *o*-sulfonate), prepd. with  $o-HOC_6H_4SO_3Na$ . 2,6-Dibromobenzenoneindo-2'-Na sulfonatephenol (2,6-dibromophenolindo-*m*-phenol - *m*-sulfonate). Benzenoneindo-*o*-phenol (phenolindo-*o*-phenol),  $O:C_6H_4:NC_6H_4OH$ , from *o*-quinonechloroimide and phenol. The leuco product was crystd. from  $H_2O$ ; it is colorless, m. 168.5–9.8°. 3-Methylbenzenoneindo-*o*-phenol (*m*-cresolindo-*o*-phenol); the yield was very poor, the leuco compd. could not be obtained in cryst. form. 2-Bromobenzenoneindo-*o*-phenol (2-bromophenolindo-*o*-phenol) 1-in cryst. form. 2-Bromobenzenoneindo-*o*-phenol (2-bromophenolindo-*o*-phenol).  $O:C_6H_4:NC_6H_4OH$ , from 1,2- $C_6H_4(OH)SO_3Na$  and quinonechloroimide. The mono-

Na salt was pptd. with  $\text{CO}_2$  and recrystd. from abs. EtOH. 1-Naphthenone-2-sulfonic acid-*indo-3'-methylphenol* (1-naphthol-2-sulfonic acid-*indo-o-cresol*). The di-Na-salt forms crystals of green-bronze color; for mono-Na salt, see previous compd. 1-Naphthenone-2-sulfonic acid-*indo-3',5'-dichlorophenol* (1-naphthol-2-sulfonic acid-*indo-3',5'-dichlorophenol*); the di-Na salt forms bronze-colored crystals, blue in transmitted light. 1-Naphthenone-2-sulfonic acid-*indo-3',5'-dibromophenol* (1-naphthol-2-sulfonic acid-*indo-3',5'-dibromophenol*). The leuco compd. m.  $190^\circ$ . Benzenone-*indo-3'-methylaniiline* (*o-toluidine-indophenol*),  $\text{O}:\text{C}_6\text{H}_4:\text{NC}_6\text{H}_4\text{MeNH}_2$ , could not be purified; the leuco compd., prepd. by reduction with  $\text{H}_2\text{S}$ , m.  $148^\circ$ . XIV. Equilibrium potentials of sodium 2,6-dibromobenzenoneindophenol-2'-sulfonate, sodium 2,6-dibromobenzenoneindophenol-3'-sulfonate, 2,6-dichlorobenzenone-*indo-2'-chlorophenol*, and 2,6-dimethylbenzenoneindophenol. WALLACE L. HALL, PAUL W. PREISLER AND BARNETT COHEN. *Ibid* No. 71, 26 pp.—The e. m. f.,  $E'_0$ , corresponding to an equimol. mixt. of oxidant and reductant was detd. at different  $p_{\text{H}}$  values and  $30^\circ$ . The "N" potential  $E_0$  corresponding to  $p_{\text{H}} = 0$  was calcd. In the succession corresponding to the substances in the heading, the values of  $E_0$  were: 0.6834, 0.6906, 0.6919, 0.5688. Dissocns. ( $\text{pK}$  log  $1/K$ ) were detd.: the const. of the oxidant  $\text{pK}_0 = 6.07, 7.40, 6.16, 8.9$ ; of the reductant  $\text{pK}_{\text{H}} = 7.01, 7.12, 6.89, 10.0$ .  $\text{pK}_{\text{r}} = 10.22, 8.93, 9.21, 10.9$ . The reversal in magnitudes of  $\text{pK}_0$  and  $\text{pK}_{\text{H}}$  in the 2nd compd. produces a unique alteration in the character of the usual  $E'_0:p_{\text{H}}$  curve of indophenol systems. The 1st 3 compds. occupy a position on the extreme electropositive side of the indophenol series. A list of oxidation-reduction indicators is presented with their  $E'_0$  between  $p_{\text{H}} = 5.0$  and  $9.0$  at intervals of  $0.2 p_{\text{H}}$ . A means of distinguishing between dissociations in the oxidant and those in the reductant is described. The influence of substitution by  $\text{SO}_3\text{H}$ , Cl, Me is discussed.

A. R. MEYER

The natural rotation of polarized light by optically active bases. II. The rotation of *d*- $\alpha$ -phenylethylamine and its hydrochloride in solution with remarks concerning the rotation of active tetrahydroquinoline. WOLFGANG LEITHE. *Monatsh.* 51, 381-5 (1929); cf. *C. A.* 22, 3663.— $[\alpha]_D^{15}$  for solns. of *d*-PhCHMeNH $_2$  (b.  $185^\circ$ ,  $d_{15} = 0.9561$ ,  $[\alpha]_D^{15} = +40.67^\circ$ ) and its HCl salt (m.  $171^\circ$ ), in various solvents at varying concns., has been measured. The values for the *sp. soln. vol.*,  $V_L$ , as calcd. from the formula  $V_L = 1/p(100/d_{\text{soln.}} - 100 - p/d_{\text{solvent}})$ , where  $p = \text{g. substance per 100 g. of soln.}$ , are found to parallel the values for  $[\alpha]_D^{15}$ .

L. F. AUDRIETH

Methylurethans of the isomeric  $\alpha$ -hydroxyphenylethyldimethylamines and their mitotic activity. EDGAR STEDMAN AND ELLEN STEDMAN. *J. Chem. Soc.* 1929, 609-17.—The substances heretofore examd. include 2 series of isomeric methylurethans, *viz.*, the dimethylaminophenyl esters of methylcarbamic acid,  $\text{HNMeCO}_2\text{C}_6\text{H}_4\text{NMe}_2$ , and the methylurethans of the hydroxybenzylidimethylamines,  $\text{NHMeCO}_2\text{C}_6\text{H}_4\text{CH}_2\text{NMe}_2$ . None of the compds. of these series contains an asym. C, and in view of the known difference in activity of the enantiomorphs of certain physiol. active substances, expts. have been carried out with the object of introducing such asymmetry into the latter of the above series of isomerides. For this purpose, the methylurethans of the isomeric  $\alpha$ -hydroxyphenylethyldimethylamines have been prepd., this particular series being chosen because the introduction of an asym. C is effected with the min. structural alterations necessary for this purpose. Unfortunately, these urethans have not yet been obtained in optically active forms. In the meantime, the results obtained with the *dl*-bases are here recorded. The 3 isomeric urethans were prepd. by conversion of the methoxybenzaldehydes into the methoxyphenylmethylcarbinols *via* Grignard, followed by treatment with HBr; the corresponding bromides thereupon react with  $\text{Me}_2\text{NH}$  to give the  $\alpha$ -methoxyphenylethyldimethylamines, which on demethylation by HBr yielded the phenols and finally the methylurethans,  $\text{NHMeCO}_2\text{C}_6\text{H}_4\text{CHMeNMe}_2$ , by interaction with MeNCO under appropriate conditions. The following compds. are described: *m*-methoxyphenylmethylcarbinol,  $b_{14.5} 133^\circ$ ;  $\alpha$ -*m*-methoxyphenylethyldimethylamine,  $b_{17} 118-9^\circ$  (HCl salt, m.  $105^\circ$ ; methiodide,  $\text{C}_{12}\text{H}_{13}\text{ONi}$ , pale cream, m.  $142^\circ$ );  $\alpha$ -*m*-hydroxyphenylethyldimethylamine, m.  $87-8^\circ$  (HCl salt,  $\text{C}_{10}\text{H}_{15}\text{ON} \cdot \text{HCl}$ , m.  $197-8^\circ$ ; methiodide, micro-cryst., m.  $160^\circ$ );  $\alpha$ -*o*-methoxyphenylethyldimethylamine,  $b_{12} 105-7^\circ$ ,  $b_{13.5} 108.5^\circ$  (HCl salt, an oil; methiodide,  $\text{C}_{12}\text{H}_{13}\text{ONi}$ , m.  $136-7^\circ$ );  $\alpha$ -*o*-hydroxyphenylethyldimethylamine,  $b_{14} 112-4^\circ$  (HCl salt,  $\text{C}_{10}\text{H}_{15}\text{ON} \cdot \text{HCl}$ , m.  $136-7^\circ$ );  $\alpha$ -*p*-methoxyphenylethyldimethylamine,  $b_{14} 118^\circ$  (HCl salt,  $\text{C}_{11}\text{H}_{17}\text{ON} \cdot \text{HCl}$ , m.  $213^\circ$ ; methiodide, m.  $128-30^\circ$ ); di[ $\alpha$ -*p*-methoxyphenylethyl]dimethylammonium bromide,  $\text{C}_{20}\text{H}_{25}\text{O}_2\text{NBr} \cdot \text{H}_2\text{O}$ , thick plates, m.  $109^\circ$ ;  $\alpha$ -*p*-hydroxyphenylethyldimethylamine, m. about  $115^\circ$  (HBr salt, m.  $178^\circ$ ; HCl salt,  $\text{C}_{10}\text{H}_{15}\text{ON} \cdot \text{HCl}$ , m.  $183^\circ$ ). Methylurethan of  $\alpha$ -*m*-hydroxyphenylethyldimethylamine,  $\text{C}_{13}\text{H}_{15}\text{O}_2\text{N}_2$ , m.  $86^\circ$  (HCl salt, m.  $169^\circ$  (effe-

vescence); *methiodide*,  $C_{11}H_{21}O_2N_2I$ , m.  $130^\circ$  (effervescence)). *Methylurethan of  $\alpha$ -o-hydroxyphenylethylidimethylamine*, m.  $90^\circ$  (HCl salt (I) extremely hygroscopic; *methiodide*,  $C_{11}H_{21}O_2N_2I$ , m.  $148^\circ$  (effervescence)). *Methylurethan of  $\alpha$ -p-hydroxyphenylethylidimethylamine*, unknown in free state (HCl salt,  $C_{11}H_{18}O_2N_2 \cdot HCl$ , m.  $203^\circ$ ; *methiodide* (II), m.  $173^\circ$  (effervescence)). The 3 urethans have been tested for miotic activity in the form both of their HCl salts and methiodides by instillation into cats' eyes, 1.5% solns. of these substances in physiol. salt solns. being employed. In case of (I) the free urethan was dissolved in the calcd. amt. of 0.153 N HCl and dil'd. to 1.5% with physiol. salt soln. With the exception of (II), which had no action at this diln., a contraction of the pupil resulted in each case, the extent of the miosis differing with the various substances employed. The estimated order of activity is: *m*-HCl > *o*-MeI > *p*-HCl, *o*-HCl, *m*-MeI > *p*-MeI. This order can of course only be regarded as provisional until the activities on other organs have been compared. It should, however, be noted that the observed activities of *p*-HCl, *o*-HCl, *m*-MeI were quite small in the dilns. used, the *m*-HCl and *o*-MeI being very much greater. The miotic activity of *m*-HCl was intense and persistent, probably approaching that of physostigmine.

W. O. EMERY

Some ureas and thioureas derived from vanillylamine. Relations between constitution and taste of pungent principles. N. A. LANGE, H. L. EBERT AND L. K. YORSE. *J. Am. Chem. Soc.* **51**, 1911-4 (1929).—Vanillylamine-HCl and KCNO in  $H_2O$  give 90% of vanillylurea, m.  $178.5^\circ$  (all m. p. cor.); the thiourea, m.  $167.5^\circ$  (60% yield). PhCNO gives 63% of phenylvanillylurea, m.  $190.5^\circ$ ; thiourea, m.  $138-8.5^\circ$ . *p*-Tolyl-vanillylthiourea, m.  $138.5-9^\circ$ ; *o*-tolyl deriv., m.  $138-8.5^\circ$ . The last three thioureas have the property of pungency but to a lesser degree than capsaicin. None of the compds. has a sweet taste, the effect of the Ph and  $MeC_6H_4$  groups, which are known to repress the sweetness of compds., predominating over the favorable effect of the MeO group; the slightly bitter taste which is characteristic of many thioureas was also observed in several of these compds.

C. J. WEST

Preparation of *o*-nitroacetophenone. WM. O. KERMAK AND JAMES F. SMITH. *J. Chem. Soc.* **1929**, 814-5.—In prepg. *o*- $O_2NC_6H_4Ac$  (I) by Gevekoht's method [*Ann.* **221**, 323 (1883)] from *Et o*-nitrobenzoylacetate (II) with  $H_2SO_4$ , *o*-nitrobenzoylacetone (III) was obtained in large quantities as a by-product, probably because of hydrolysis of the  $-CO_2Et$  and loss of  $CO_2$  from II. The wt. of acid was varied to 50, 36 and 28%, giving the following yields of I and III; 27 and 52%, 22 and 68%, and 16 and 70%, resp. To avoid this hydrolysis, the boiling was carried out for 7 hrs. in EtOH contg. 10%  $H_2SO_4$ ;  $H_2O$  was then added and the soln. dist'd. to remove EtOH and EtOAc; after refluxing for 1 hr., cooling and extg. with  $Et_2O$ , distn. of the ext gave 75% of I and no III.

A. S. CARTER

The synthesis of acetosyringone. F. MAUTHNER. *J. prakt. Chem.* [2], **121**, 255-8 (1929).—Acetylpyrogallol 2,6-di-*Me* ether (I) treated with  $AlCl_3$  in  $PhNO_2$  yields 3,5-dimethoxy-4-hydroxyacetophenone ("acetosyringone") (II), white crystals from ligroin, m.  $122-3^\circ$ ; *p*-nitrophenylhydrazone, m.  $189-90^\circ$ . II methylated with MeI and KOH yields trimethylgalloacetophenone, previously described. An earlier paper (cf. *C. A.* **22**, 1966), reported the rearrangement of II by  $ZnCl_2$  to yield 3,4-dihydroxy-4-methoxyacetophenone, a *m*-rearrangement; whereas this latter work with  $AlCl_3$  checks the results of Rosenmund and Schnurr (cf. *C. A.* **22**, 1579), who obtained only *o*,*p*-rearrangements of Ac derivs. of phenols.

M. A. DAHLEN

Diastereoisomerism. I. Configuration of ephedrine. HERMANN EMDER. *Helv. Chim. Acta* **12**, 365-76 (1929).—Ephedrine (I),  $PhCH(OH)CH(NHMe)Me$ , contains 2 different asym. C atoms, of optical rotations *a* and *b*. It must therefore have 6 optical isomers: (*a* + *b*), (*a* − *b*), (−*a* + *b*), (−*a* − *b*), and the 2 *dl*-compds. (−)-I hydrate. The  $H_2O$  soln. of the HCl salt is treated with an excess  $K_2CO_3$  and ext'd with  $Et_2O$ , yielding a viscous oil, crystg. in the presence of  $H_2O$  as the hydrate, m.  $39-40^\circ$ . The  $H_2O$ -free base gives in  $H_2O$   $[M]_D^{20}$   $18.5^\circ$ . Heating for 24 hrs. at  $100^\circ$  does not change the compd., showing that the results of Gadamer (*Arch. Pharm.* **246**, 574, 1908) for the EtOH soln. of the compd. ( $[\alpha]_D^{20} -6.3^\circ$ ) corresponded to the hydrate. (−)-I.HCl, m.  $216^\circ$ ,  $[M]_D^{20} -72^\circ$ . The  $H_2O$  soln. reacts faintly acid to litmus, the solns. in org. solvents are neutral. Solubilities at room temp. and at the b. ps., resp., (parts of solvent for 1 part of solute):  $H_2O$ , 5, 1; abs. EtOH, 28, 9;  $CHCl_3$ , 3000, 2000;  $Et_2O$ , insol., nearly insol. (+)-Pseudoephedrine (II). Free base, 6 g. of II.HCl are dissolved in 30 cc.  $H_2O$ , and 30 cc. of N NaOH is added. II seps. in milky needles (4.9 g., m.  $117.5^\circ$ ), can be titrated with HCl and methyl red. The EtOH soln. gives  $[M]_D^{20}$   $87.5^\circ$ . It is hardly sol. in  $H_2O$ , sol. in  $Et_2O$  and  $Me_2CO$ , easily recrystd. from

the latter. (+)-II.HCl, m. 179°,  $[M]_{D}^{20}$  123.2°, much more sol. in H<sub>2</sub>O, EtOH, CHCl<sub>3</sub> and Me<sub>2</sub>CO than (—)-I.HCl. The 2 compds. are best sep'd. by crystn. from EtOH. (+)-Desoxyephedrine: [(+)-1-phenyl-2-methylaminopropane, (+)-β-phenylisopropylmethylamine]. A soln. of 3 g. NaOAc in 40 cc. H<sub>2</sub>O is made neutral to litmus with a few drops of AcOH; 2 g. of Pd-BaSO<sub>4</sub> catalyst is added, with 9.8 g. of (+)-bromopseudoephedrine-HBr, (or 7.2 g. of (+)-chloropseudoephedrine-HCl), and agitated under H<sub>2</sub> at room temp. About 90% of the theoretical H<sub>2</sub> is absorbed in 2–3 hrs., the catalyst is filtered off and the product is steam distd. from the filtrate after addn. of NaOH. There remains a small residue of (+)-didesoxyephedrine. The 1st distillate is neutralized with HCl (methyl red) and crystd. from abs. EtOH (soly., 1:4). Yield, 80–90%. (+)-Desoxyephedrine-HCl. The residue from the above is extd. with Et<sub>2</sub>O, dried and distd. under a high vacuum. The HCl salt, m. 172°, is sol. in H<sub>2</sub>O,  $[M]_{D}^{25}$  33°. (+)-Didesoxyephedrine. A viscous oily residue from the above prepn., distd. below 1 mm., m. 70°, b<sub>0.6</sub> 165°. The chloroplatinate, recrystd. from H<sub>2</sub>O, C<sub>20</sub>H<sub>30</sub>N<sub>2</sub>Cl<sub>6</sub>Pt, m. 224–5° (decompn.). The base showed peptizing action,  $[M]_{D}^{18}$  78.8°, showing no mutarotation. A comparison of the  $[M]$  values show that  $a > b$ , that the natural (—)-I corresponds to the (a — b) configuration and the natural (+)-II to the (a + b). The crystd. (—)-I is a hydrate (m. 39°) while the crystd. (+)-II is anhyd. II. Steric inversion of ephedrine with hydrochloric acid. *Ibid* 377–84.—2.5 g. of (—)-I or (+)-II are heated in a sealed tube at 100° with 25 cc. of 25% HCl. After cooling,  $[\alpha]_{D}^{20}$  is measured. After 50 hrs. the inversion into the equil. concn. of I and II is completed. With 25% HBr instead of HCl, the process requires 280 hrs. Only traces of the HCl salts are found, but a little more of the HBr salts. With 38% HCl, the yield of I and II HCl salts is practically quant. III. Chloro- and bromoephedrine. *Ibid* 384–99.—(+)(—)-Chloropseudoephedrine-HCl, PhCHClCHMeNHMe HCl (III). (a) From (—)-I.HCl, and PCl<sub>5</sub>: 60 cc. CHCl<sub>3</sub> and 60 g. PCl<sub>5</sub> are put in a wide-mouth glass-stoppered bottle, and after cooling with ice 40 g. of powd. (—)-I HCl is added in 0.5 g. portions in about 10 mins., shaking vigorously after each addn. The bottle is then shaken mechanically for 2 hours. The reaction mass is then decanted into a 750 cc. beaker, leaving the excess PCl<sub>5</sub> in the bottle. After rinsing with 20 cc. CHCl<sub>3</sub>, 500 cc. Et<sub>2</sub>O is added and the product allowed to stand. The product crystallizes out, is filtered under suction, washed with Me<sub>2</sub>CO and dried in a vacuum desiccator. Yield, 99.4%. A few recrystns. from EtOH yields III optically pure. (b) From (—)-I.HCl and SOCl<sub>2</sub>. Similarly, using 20 cc. SOCl<sub>2</sub>, 20 cc. CHCl<sub>3</sub> and 10 g. of the salt. The reaction is slower, and after 0.5 hr. 100 cc. Et<sub>2</sub>O is added and the crystd. III is treated as above. Yield 93%,  $[\alpha]_{D}^{20}$  85°. (c) From (+)-II.HCl and SOCl<sub>2</sub>. Similarly, from 2 g. of salt, 5 cc. CHCl<sub>3</sub> and 4 cc. SOCl<sub>2</sub>. The addn. of 100 cc. Et<sub>2</sub>O ppts. 2.15 g. of yellowish product,  $[\alpha]_{D}^{18}$  73°. III is slightly acid to litmus and neutral to Congo, m. 201°, hydrolyzed completely in 20 hrs. at 100°, more rapidly in the presence of MgO, NaOAc, (CO<sub>2</sub>Na)<sub>2</sub>, Na<sub>3</sub>PO<sub>4</sub>. One-half of the Cl may be titrated with AgNO<sub>3</sub> in the cold, the other half after 24 hrs. heating to 100°. The total Cl may be titrated after vigorous stirring for 2 hrs. with MgO.  $[M]_{D}^{20}$  25.6°, and is the same in H<sub>2</sub>O and in 25% HCl. The rotary dispersion is normal. Free (+)-chloropseudoephedrine, PhCHClCHMeNHMe (IV), yellow oil, with a strong odor similar to that of II, too unstable to be purified for analysis. Chloroplatinate: 1 g. of III in 10 cc. of N HCl is treated with 3 cc. of a 34% PtCl<sub>4</sub>. The compd., C<sub>20</sub>H<sub>30</sub>N<sub>2</sub>Cl<sub>6</sub>Pt ppts., first amorphous, then as orange-red crystals, and is recrystd. from boiling H<sub>2</sub>O, m. 188° (decompn.). Chloraurate: From 1 g. III in 25 cc. of N HCl, with 5 cc. of 20% AuCl<sub>3</sub>, light yellow needles, m. 128°, decompd. by light or by boiling H<sub>2</sub>O, recrystd. from EtOH. Investigation of the steric inversion of III. One part of III heated for 9 hrs. with 10 parts of PCl<sub>5</sub> in a sealed tube loses 1/7 of its rotary power, and is thereby not fractionated, whether by decompn. or by inversion. Heating for 31 days at 60° with 10 parts of CHCl<sub>3</sub> has no effect. Hydrolysis of III. III, heated to 100° in a sealed tube with H<sub>2</sub>O, is completely hydrolyzed in 20 hrs. to a mixture of (—)-I and (+)-II, in which the latter predominates. An expt. at 60° showed the reaction to be approx. monomol., the final product corresponding to 38% of (—)-I and 62% of (+)-II after 84 hrs. At room temp. III shows a very slow mutarotation,  $[\alpha]_{D}^{20}$  decreasing from 116.6° to 85.70° after 87 days. (+)-Bromopseudoephedrine-HBr (V), from 12.9 g. of (—)-I.HBr, 50 g. PBr<sub>3</sub> and 60 cc. CHCl<sub>3</sub>. After 3 hrs. of shaking, the product is decanted off and treated with 500 cc. of Et<sub>2</sub>O and filtered off. Yield, 98% of pure product, m. 174–5°.  $[M]_{D}^{18}$  385°. The H<sub>2</sub>O soln. is faintly acid to litmus and neutral to Congo. It turns acid to Congo on standing or heating. It is completely hydrolyzed

by heating for 1 hr. at 100° with H<sub>2</sub>O. The H<sub>2</sub>O soln. shows a more rapid mutarotation than that of the Cl compd., being 0.5 completed in 290 hrs. and corresponding, like that of (–)-I-HBr and III, to a monomol. reaction. The reaction velocity const. varies, however, somewhat on account of the hydrolysis which is taking place simultaneously. Both hydrolysis and mutarotation take place much faster at 60°. (–)-Bromoephedrine-(I). By inversion from the (+)-compd., as follows: 5 g. of V and 10 cc. CHCl<sub>3</sub> are kept around 60° for 20 days in a sealed tube, or the mixt. is refluxed until it becomes cryst. (about 24 hrs.). This yields 4.1 g. of pure product [ $\alpha$ ]<sub>D</sub><sup>20</sup> –90.2°. Pptn. with Et<sub>2</sub>O yields an additional crop of [ $\alpha$ ]<sub>D</sub><sup>20</sup> 24°, which is a mixt. of the 2 optical isomers. Inversion of (+)-II-HBr into (–)-bromoephedrine-HBr. From 9 g. of (+)-II-HBr, 30 cc. CHCl<sub>3</sub> and 35 g. PBr<sub>5</sub>. Recrystd. from EtOH, it m. 174.5°, [ $M$ ]<sub>D</sub><sup>20</sup> –287°. This (–)-compd. is much less soluble in H<sub>2</sub>O than the (+)-isomer, and shows similarly the mutarotation and hydrolysis, but more markedly. IV. Steric inversion of ephedrine with sulfuric acid. *Ibid* 399–405.—(+)-II *O*-sulfuric ester, from (–)-I. Twenty g. of natural (–)-I-HCl are added in 40 fractions in 10 min. to 100 g. of ice-cooled concd. H<sub>2</sub>SO<sub>4</sub>. After shaking and standing, the product is poured onto 200 g. of cracked ice and 300 cc. of EtOH is added. (+)-II *O*-sulfuric ester (VI) seps. as white needles, m. 248–50° (decompn.), show no mutarotation. [ $M$ ]<sub>D</sub><sup>20</sup> 272°.

The rotation dispersion is normal. The mother liquor yields a little more VI with some (+)-II and (–)-I sulfate. *Apoephedrine*, and *didesoxyephedrine*, [PhC(CHMeNHMe)]<sub>2</sub> (VII). Twenty g. of I HCl in 100 g. of ice-cooled H<sub>2</sub>SO<sub>4</sub> is allowed to stand for 5 days. It is then steam distd. after treating with 250 g. of 40% NaOH. The distillate contains MeNH<sub>2</sub>, (+)-II, (–)-I and an unidentified non-basic oil with an odor of roses. The main product does not distil, and is extd. with Et<sub>2</sub>O and distd. under 0.7 mm. The main product b. 172° and contains 4.4% O<sub>2</sub>. VII is therefore different from didesoxyephedrine. *No didesoxyephedrine without catalyst*.—To test whether the formula PhC(CHMeNHMe)NMeCHMeCH<sub>2</sub>Ph is that of didesoxyephedrine a soln. of 3.89 g. of III and 3.27 g. of (+)-desoxyephedrine-HCl in 50 cc. H<sub>2</sub>O is prepd. Part of it is treated with NaOAc and [ $\alpha$ ] of both portions is compared from time to time. The portion without NaOAc only shows the mutarotation of III, but the other shows a much greater mutarotation, indicating that NaOAc accelerates the hydrolysis of III. The working up of the NaOAc soln. gave no didesoxyephedrine, showing that VIII is not the correct formula.

G. CALINGAERT

**Synthesis of ephedrine and structurally similar compounds.** II. Synthesis of some ephedrine homologs and the resolution of ephedrine. RICHARD H. F. MANSKE AND TREAT B. JOHNSON. *J. Am. Chem. Soc.* 51, 1906–9(1929); cf. C. A. 23, 1104.—In extending the reaction leading to the synthesis of ephedrine (I), the following compds. were prepd.: PhCH(OH)CHRNHMe, where R is Me and Et, the HCl salts of which m. 198° and 226° (all m. ps. cor.), resp.; PhCH(OH)CHMeNHR, where R is CH<sub>2</sub>CH<sub>2</sub>OH, PhCH<sub>2</sub> and PhCH<sub>2</sub>CH<sub>2</sub>, m. p. of the HCl salts, 166°, 184–5° and 207–8°, resp.; RCH(OH)CHMeNHMe, where R is *p*-EtC<sub>6</sub>H<sub>4</sub> and 2,5-Me<sub>2</sub>C<sub>6</sub>H<sub>3</sub>, and *p*-MeC<sub>6</sub>H<sub>4</sub>CH(OH)CH<sub>2</sub>NHMe, whose HCl salts m. 208°, 221° and 208°, resp. Synthetic I may be resolved into its *d*- and *l*-isomers, by means of mandelic acid; the *l*-isomer is identical with the base from the Chinese drug, Ma Huang. Natural *l*-I lends itself admirably to the prepn. of pure *l*-mandelic acid.

C. J. WEST

**Identification of *o*-, *m*- and *p*-hydroxybenzoic acids.** F. F. BLICKE AND F. D. SMITH. *J. Am. Chem. Soc.* 51, 1947–9(1929).—Lyman and Reid (C. A. 11, 1830) recommend the *p*-nitrobenzyl esters as suitable for the identification of HOC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H; their method, however, gives the dinitrobenzyl derivs in part, which, because of ease of crystn. and high mol. wt., are more suitable for this purpose. The dinitrobenzyl derivs. of *o*-, *m*- and *p*-HOC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H, m. 137–9°, 142–4° and 196–7°, resp., were prepd. by heating 1.25 g. *p*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>CH<sub>2</sub>Br in 10 cc. Me<sub>2</sub>CO and 0.35 g. acid, 0.3 g. NaOH and 4 cc. H<sub>2</sub>O for 2 hrs; the *p*-deriv. is quite insol. in Me<sub>2</sub>CO, the *o*-deriv. is fairly sol., while the *m*-deriv. is intermediate in soly. The *p*-nitrobenzyl esters, m. 97–8°, 106–8° and 180–2°, resp., were prepd. by adding 2.15 g. *p*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>CH<sub>2</sub>Br during 0.5 hr. to a boiling soln. of 1.4 g. acid and 0.55 g. NaOH in 5 cc. H<sub>2</sub>O to which 15 cc. Me<sub>2</sub>CO had been added, then heating 1 hr., cooling, dilg. with H<sub>2</sub>O and pptg. with HCl. Sapon. of the dinitrobenzyl derivs. (0.5 g.) with 3 g. K<sub>2</sub>CO<sub>3</sub> in 30 cc. 60% EtOH gives the nitrobenzyl ethers, m. 166–8°, 193–6° and 259–61°, resp.

C. J. WEST

**Studies on  $\gamma$ -resorcylic acid.** F. MAUTHNER. *J. prakt. Chem.* (2) 121, 259–65 (1929).—Directions are given for the prepn. of 2,6-dimethoxybenzoic acid, crystals from

pH, m. 186–7°; amide, m. 207–8°; nitrile, m. 118°; Me ester, m. 88°.

M. A. DAHLEN

The reactions of tropic acid and of the tropeines. MARC CHAMBER. *Bull. sci. pharmacol.* 36, 222–6(1929).—The different reactions obtained with tropic acid and its compds., hyoscyamine, atropine, hyoscyne and scopolamine are discussed. A. E. M.

Higher terpene compounds. XXXV. Constitution of bisabolene. L. RUZICKA AND A. G. VAN VEEN. *Ann.* 468, 133–43(1929); cf. C. A. 22, 1347.—Dehydrogenation of bisabolene (I) with S or Se does not give  $C_{15}H_{24}$  hydrocarbons, their formation apparently being hindered by the middle semicyclic double bond; the bond appears to wander during the operation for the dehydrogenation product gives terephthalic acid on oxidation with  $CrO_3 \cdot H_2SO_4$ ; this does not result on the oxidation of I. Natural I or that regenerated from the HCl deriv. and  $O_3$  give  $Me_2CO$  and levulinic acid as well as  $(CH_2CO_2H)_2$ . Catalytic reduction gives a tetrahydro deriv.,  $b_{18}$  125°,  $d_4^{15}$  0.857, which yields a hexahydro deriv. on further reduction;  $C(NO_2)_4$  in EtOH gives a yellow color. With  $O_3$  this yields methylheptanone and 4-methylcyclohexanone, identified by oxidation to the acids. These results indicate that I consists principally of the  $\gamma$ -form (cf. R. and Capato (C. A. 19, 2333)). XXXVI. Constitution of zingiberene. Ibid 143–62.—Crude zingiberene (I) in  $Et_2O$  at 0°, satd. with dry HCl, gives some bisabolene tri-HCl, m. 82°.  $AcOH \cdot H_2SO_4$  gives isozingiberene,  $b_{14}$  130–5°,  $d_4^{15}$  0.910,  $n_D^{20}$  1.506, which yields a di-HCl salt, m. 168°. The action of  $O_3$  upon I gives  $Me_2CO$ ,  $(CH_2CO_2H)_2$  and levulinic acid; part of the  $Me_2CO$  probably comes from I, the rest from the bisabolene (II) contained therein. The catalytic dehydrogenation of a mixt. of the hexahydro derivs. of I and II gave as the only product 2-methyl-6-p-tolylheptane,  $b_{12}$  135° (C too high), which was synthesized from  $p-MeC_6H_4MgBr$  and methylheptanone, dehydrated with  $K_2SO_4$  and reduced with Pt,  $b_{18}$  135–6°,  $d_4^{15}$  0.8524,  $n_D^{16}$  1.4832. A tetrahydro deriv. of the crude I,  $b_{18}$  130–5°,  $d_4^{15}$  0.842,  $n_D^{20}$  1.463, and  $O_3$  give a methylheptanone, whose semicarbazone m. 154°. I and  $N_2CHCO_2Et$ , heated 100 hrs. in  $CO_2$  on the  $H_2O$  bath, give an acid,  $C_{17}H_{28}O_2$ ,  $b_{6.3}$  170–80°. Dihydrozingiberene (mixed with II),  $b_{15}$  135–6°,  $d_4^{15}$  0.865,  $n_D^{20}$  1.4881; HCl gives only an amorphous product; it does not condense with  $N_2CHCO_2Et$ ; dehydrogenation gives cadalene;  $O_3$  gives  $(CH_2CO_2H)_2$ ,  $Me_2CO$  and levulinic acid and aldehyde. Oxidation with  $KMnO_4$  of the ozonide of the dihydro deriv. gives an ester,  $C_{14}H_{24}O_6$ ,  $b_{0.3}$  140–55°, further oxidized by  $NaOBr$  to the ester,  $C_{14}H_{24}O_6$ ,  $b_{0.3}$  140–50°.

C. J. WEST

Kessyl alcohol. V. New constituents of "Kesso" oil. Y. ASAHINA AND S. NAKANISHI. *J. Pharm. Soc. Japan* 49, 135–40(1929).—The cryst. substance sometimes found in "Kesso" oil (I) was found to be kessyl acetate (II) contg. 1 mol.  $H_2O$  of crystn. Previous work by Bertram and Gildemeister (*Arch. Pharm.* 228, 483) and also by Asahina and Hongo (C. A. 18, 2510) showed that II could not be crystd. even when cooled to –20°. Introduction of some of the crystals, however, into the 70% alc. soln. of II resulted in an immediate crystn. The crystals, m. 60–1°,  $b_{774}$  280–3°,  $b_{4.5}$  148–50°,  $[\alpha]_D^{18}$  –62.74° (–65.1° for the anhyd. compd.). Boiling of "blue oil" (the high boiling fraction of I from which kessyl alc. (III) has been removed) with  $H_2O$  gave kessoglycerol (IV)  $C_{15}H_{28}O_3$ ,  $[\alpha]_D^{18}$  –15.13°. Oxidation of IV with  $AcOH$  and  $Na_2Cr_2O_7$  gave kessotriketone, m. 208°. Semicarbazone, m. 208°. When roots of *Valeriana officinalis* L. v. *latifolia* Miq. grown by Toyana Pharm. Coll. were steam distd., an oil (V) ( $d_4^{20}$  0.98;  $[\alpha]_D$  –32.44°) somewhat different from I was obtained. It does not contain III. Fractional distn. of V gave a satd. compd. (IV),  $C_{19}H_{30}O_5$ , m. 119°,  $b_{760}$  259°. Sapon. of V with  $EtOH \cdot KOH$  gave kessoglycol, m. 58–9° due to the liberation of 2 Ac groups.

NAO UYEI

The oxidation of pinenes in presence of catalysts. GEORGES DUPONT AND JEAN CROUZET. *Bull. inst. pin* 1929, 101–8.—An investigation into the rate of oxidation at const. pressure and at const. vol. of pinene and nopinene obtained by very careful rectification of spirits of turpentine followed by redistn. over Na to remove the last traces of oxidation products. The oxidation curve of pure dry pinene is typical of autoxidation in which the oxidation products act as catalysts and the rate is increased by diffuse daylight, and still more by direct sunlight; the rate of oxidation at high temps. is also greatly increased by agitation. The rate of oxidation of nopinene is lower than that of pinene under the same conditions, but the curve is of the same general character as that of pinene. Co resinates increases very greatly the initial rate of oxidation of both pinene and nopinene, which first increases, reaches a max., and then rapidly decreases; this decrease is at least partly due to decompn. of the metallic salt, probably by the  $HCO_2H$  and  $AcOH$  formed by oxidation. In presence

of Co resinate the rate of oxidation is not appreciably affected by light, but is increased considerably by heat. Fe, Pb, Ni and Cr resinates,  $\text{FeCl}_3$ , I and KI behave similarly to Co resinate, but are less active. Hydroquinone, pyrogallie acid, gallic acid, activated charcoal, Ce oxide, Th oxide,  $\text{Hg}(\text{AcO})_2$ ,  $\text{SnCl}_2$ , titanie acid, spongy Pt reduced Cu, freshly prepd. Cu resinate and S have anti-O properties, which disappear after various periods of time, the anti-O properties of the 1st 4 being still quite marked after 1000 hrs. Certain substances act as reversible catalyzers, the one with the clearest action being Mn resinate; reversal of the properties takes place quite suddenly after a crit. period, which depends on the conditions of the expts. The interpretation of the results is briefly discussed in the light of Moureu's theory of anti-O and pro-O action.

#### A. PAPINEAU-COUTURE

**Study on the addition problem in a case from the camphene series.** P. LIPP AND MARIA HOLL. *Ber.* 62B, 499-504(1929).—The chief factors playing a role in addns. at an ethylene union are the chem. polarity of the ethylene C atoms and that of the adding substance or its degree of dissocn., the addn. velocity, which need not be the same at both unsatd. C atoms, and finally the spatial relations resulting at the points of addn. from different substituents on the ethylene C atoms. Acids contg. O may in part add in 2 forms, ionic and radical; thus,  $\text{H}_2\text{SO}_4$  can add to  $\text{C}_2\text{H}_4$  as "monohydrate" with formation of  $\text{EtOSO}_3\text{H}$  or as "oleum" with primary formation of  $\text{HOCH}_2\text{CH}_2\text{SO}_3\text{H}$ , and  $\text{AcOH}$ , under the influence of small quantities of  $\text{H}_2\text{SO}_4$ , can add to amylenes to form  $\text{EtCM}_2\text{OAc}$ , whereas in  $\text{Ac}_2\text{O}$  contg. "sulfoacetic acid" (in which there is always free  $\text{AcOH}$ ) it can form *p*-Ac derivs. of phenol ethers, probably by primary addn. of HO and Ac at the 1,4-positions of the  $\text{C}_6\text{H}_4$ . L. and H. attempted to effect the latter form of addn. at the semicyclic double bond of camphene which, as is well known, adds  $\text{AcOH}$  to form isobornyl acetate (I) under the conditions of the Bertram-Walbaum reaction. With  $\text{SO}_3$  in  $\text{AcOH}$  it does not, however, give an acetoborneol as expected

but, together with much I, a compd.  $\text{C}_{10}\text{H}_{16}\text{O}_3\text{S}$  (II),  $\text{CH}_2-\overset{\text{CH}_2}{\underset{\text{CH}_2-\text{SO}_2}{\text{C}}}-\text{CH}-\text{O}$  shown to be a

sultone by its decompn. with  $\text{NaOH}$  or  $\text{Ba}(\text{OH})_2$  into the salts of the corresponding hydroxysulfonic acid (III). Attempts to prove the structure II by oxidation of III to Reichler's camphorsulfonic acid (IV) met with difficulties and the inverse process was accordingly used; IV was reduced in alk. soln., giving 2 stereoisomeric 2-hydroxy-camphane-*o*-sulfonic acids, an *endo*-form (V) with a little *exo*-form (VI). V can be converted into VI and the VI spontaneously loses 1 mol.  $\text{H}_2\text{O}$  and yields II. 2-Hydroxy-camphane-*o*-sulfonic lactone (II) (38 g. crude or 3.8 g. pure product from 60 g. camphene heated 10 hrs. at  $100^\circ$  with 15 g.  $\text{SO}_3$  in 75 g.  $\text{AcOH}$ ),  $b_{0.8}$  147.5- $8^\circ$  (temps. cor.),  $m$  133.5°, mol. wt. in freezing  $\text{C}_6\text{H}_6$  211.0-7.4. Salts of III: Na; Ba;  $\text{NH}_4$ , decomp. 186°. Salts of V:  $\text{NH}_4$ , decomp. 232°; *p*-toluidine,  $m$ . 152-3° (gas evolution) (*p*-toluidine salt of IV,  $m$ . 161-2° (cor.)). C. A. R.

**Synthetic camphor.** A. ULLRICH. *Metallbörse* 18, 1013-14, 1069-70(1928).—A review of the patent literature dealing with the manuf. of camphor and isoborneol

**Swann Corporation develops diphenyl on commercial scale.** D. N. HAUSEMANN *Mfrs. Record* 95, No. 20, 58-9(1929).—Methods and results of preliminary tests and mfg. operations are described.

F. I. S.

**Corrections in the chemistry of diphenyl derivatives of the "Kaufler" type, and the formation of dibenzocdiazines.** RAYMOND J. W. LE FÈVRE. Univ. College, London *J. Chem. Soc.* 1929, 733-8.—The compds. cited by Kaufler (*C. A.* 1, 1396, 2691) and related compds. have been studied by Le Fèvre and Turner (*C. A.* 21, 80), and Kuhn, Jacob and Furter (*C. A.* 21, 2891). Remfry's "malonylbenzidine" (*C. A.* 5, 2855)

is probably 4,4'- $\text{CO}.\text{CH}_2.\text{CO}.\text{NC}_6\text{H}_4\text{C}_6\text{H}_4\text{NH}_2$ , since it gives a colorless amorphous sulfate, and with excess salicylaldehyde-phenol mixt. forms a salicylidene deriv.,  $\text{C}_{27}\text{H}_{16}\text{N}_2\text{O}_8$ , light yellow,  $m$ . 298-300°. Starke's "thiocarbonyl- and carbonyl-dianisidines" (*J. prakt. Chem.* [N. S.], 59, 216) similarly form salicylidene derivs., yellow powders. The "oxalyl-*o*-tolidine" of Taussig (*Monatsh.* 25, 375) forms with salicylaldehyde a colorless powder,  $\text{C}_{27}\text{H}_{24}\text{N}_2\text{O}_8$ ,  $m$ . above  $300^\circ$ . Taussig's "oxalylbenzidine" is the 4,4'-diethyloxamido-3,3'-dimethyldiphenyl to be expected from  $(\text{COOEt})_2$  and *o*-tolidine (cf. Le Fèvre and Turner, *C. A.* 22, 1349). (*o*- $\text{H}_2\text{NC}_6\text{H}_4$ )<sub>2</sub> (I) was prepd. in 50-60%

yield by Ulmann and Bielecki's method (*Ber.* 34, 2177), except for the addn. of sand, from  $o\text{-ClC}_6\text{H}_4\text{NO}_2$  and Cu bronze with reduction with Fe and HCl. 2,2'-Disalicylideneaminodiphenyl,  $\text{C}_{26}\text{H}_{20}\text{N}_2\text{O}_2$ , yellow, m. 153-4°. I and  $\text{CS}_2$  refluxed one day in alc. gave  $N,N'$ -thiocarbonyl-2,2'-diaminodiphenyl,  $\text{C}_{13}\text{H}_{10}\text{N}_2\text{S}$ , m. 243°. I (7.4 g.) and phenanthraquinone (8.3 g.) in AcOH at 100° for 2 hrs. yielded 13,14-[ $o,o'$ -diphenylene]-dibenzot-12,15-diazine,  $\text{C}_{26}\text{H}_{16}\text{N}_2$ , (11 g.), yellow, m. 268-9°. Cases of the easy formation of 8-membered rings between the 2- and 2'-positions of  $\text{Ph}_2$  are rare (cf. Kenner and Stubbings, *C. A.* 15, 2434, and Barber and Smiles, *C. A.* 22, 3153). Such rings are probably strainless because of rotation of the  $\text{Ph}_2$  nuclei around their common axis. Täuber's method (*Ber.* 25, 129) for the prepn. of "di- $m$ -nitrodi- $o$ -aminobiphenyl" always gave probably a mixt. of chiefly the 5,5', 4,4'- and 4,5', with some 3,3'- and 3,5'-dinitro derivs., which did not yield dinitro-octadiazines. I could not be condensed with  $(m\text{-HO}_2\text{SC}_6\text{H}_4\text{CO})_2$  (Kafka, *Ber.* 24, 794).  $(o\text{-C}_6\text{H}_4\text{NHAc})_2$  (prepd. by Brady and McHugh's method, *C. A.* 17, 3496), heated with Br in AcOH, yielded about 90% of the 5,5'-di-Br deriv., m. 266-7°. 5,5'-Dibromo-2,2'-diaminodiphenyl (II), m. 140-1°. Disalicylidene deriv., yellow microcryst. powder, m. 263-5°. II and phenanthraquinone in AcOH at 100° formed 3,8-dibromo-13,14-[ $o,o'$ -diphenylene]-dibenzot-12,15-diazine,  $\text{C}_{26}\text{H}_{14}\text{Br}_2\text{N}_2$ , yellow, m. above 280°. 4,4'-Dibromo-2,2'-diaminodiphenyl, m. 192-4°, was prepd. by reduction with Fe filings of the corresponding dinitro compd. (from 2,5- $\text{Br}_2\text{C}_6\text{H}_3\text{NO}_2$  according to Ulmann and Bielecki). Disalicylidene deriv.,  $\text{C}_{26}\text{H}_{18}\text{Br}_2\text{N}_2\text{O}_2$ , m. 210-1°. The ability of the nuclei in I to rotate is indicated by the ease of  $N,N'$ -disubstitution (cf. Täuber, *Ber.* 24, 198). I and 2,4-( $\text{O}_2\text{N}$ ) $_2\text{C}_6\text{H}_3\text{Cl}$  give chiefly 2,2'-di[2'',4''-dinitrophenylamino]diphenyl,  $\text{C}_{24}\text{H}_{16}\text{N}_6\text{O}_8$ , yellow, m. 177-8°, with some  $N$ -2',4'-dinitrophenylcarbazole, red, m. 216-7°. Diphenic anhydride (III) and benzyl alc. at 160° yield benzyl H diphenate, m. 112-3°. IV (6.7 g.) and  $\alpha$ -naphthol (4.3 g.) give naphthyl H diphenate (8 g.), m. 202-3°. The  $\beta$ -mono ester m. 178-9°.

JANET D. SCOTT

**Structure of metal ketyls. I. The Schmidlin formula.** CHARLES B. WOOSTER. *J. Am. Chem. Soc.* 51, 1856-60 (1929).—The reaction of EtBr with  $\text{Ph}_2\text{CONa}$  in liquid  $\text{NH}_3$  is not identical with that between Na and a soln. of EtBr and  $\text{Ph}_2\text{CO}$  in the same solvent. In the latter reaction the  $\text{Ph}_2\text{CO}$  remains unchanged, while the EtBr gives NaBr,  $\text{NaNH}_2$  and  $\text{C}_2\text{H}_6$ . The action of  $\text{Ph}_2\text{CO}$  on  $\text{Ph}_2\text{C}(\text{ONa})\text{Na}$  gives  $\text{Ph}_2\text{CONa}$ . This shows that the Schmidlin formula for the metal ketyls is incorrect. The interpretation of the reactions of these compds. proposed by Schlenk and his co-workers is not necessarily the only alternative to be considered.

C. J. WEST

**Rubcene.** ALFRED ECKERT. *J. prakt. Chem.* [2], 121, 278-80 (1929).—Rubcene (I) is a hydrocarbon which is obtained in very small quantities as a by-product in the prepn. of fluorenone by distn. of diphenic acid with lime (cf. *C. A.* 6, 1006). Crude I is obtained when fluorene (II) is subjected to the heat of a Pt wire for 30 hrs. in the app. described by Meyer (cf. *C. A.* 11, 780), then distd. and the last fraction, which is a red resin, recrystd. from xylene; a 2nd crystn. from xylene gave 0.2-0.3 g. pure I from 30 g II; the mother liquors contain an unknown substance, m. 218°; I is stable to the action of light. When dibiphenylene-ethene in glacial AcOH is exposed to direct sunlight until all of the red crystals have disappeared, it forms fluorenone (cf. Hantzsch and Glover, *Ber.* 39, 4156 (1906)), and dibiphenylene-ethane, m. 246°, which was isolated by removal of AcOH with distn. and cooling.

N. A. LANGE

**Tautomerism of hydroxytriarylcannabinols. II.** L. C. ANDERSON. *J. Am. Chem. Soc.* 51, 1889-95 (1929); cf. *C. A.* 22, 415.—Curves and tables show the quant. absorption of ultra-violet light by  $\text{Et}_2\text{O}$  solns. of the methane, the benzenoid and the quinonoid carbinol and the fuchson of each of the following compds.: 5-chloro- $o$ -cresyldiphenylcarbinol, 5-Br deriv. and guaiacyldiphenylcarbinol. Supplementary data are given for the absorption of light by  $\text{Et}_2\text{O}$  solns. of  $\text{Ph}_3\text{CH}$ ,  $\text{Ph}_3\text{COH}$  and the methane, benzenoid and quinonoid carbinol and the fuchson of 4- $\text{HOC}_6\text{H}_4\text{CPh}_2\text{OH}$  and  $o\text{-MeC}_6\text{H}_4\text{CPh}_2\text{OH}$ . Further evidence based on spectroscopic data is presented to prove the existence of a quinonoid modification of  $\text{HOC}_6\text{H}_4\text{CPh}_2\text{OH}$ .

C. J. WEST

**Phenolphthaleins.** F. F. BLICKE AND F. D. SMITH. *J. Am. Chem. Soc.* 51, 1865-75 (1929).—Di-Et 4-fluorophthalate,  $b_{25}$  165-70°, results in 50% yield from the 4- $\text{NH}_2$  deriv. through the diazonium borofluoride; the 4-Cl deriv.,  $b_{25}$  185-90°; the 4-Br deriv.,  $b_{80}$  225° (70% yield); the 4-I deriv. is a red oil. 4-Fluorophthalic acid, m. 147-8°; 4-Cl deriv., m. 150°; 4-Br deriv., m. 170°; 4-I deriv., m. 185-6°. 4-Fluorophthalic anhydride,  $b_{740}$  260°, m. 76-8°; 4-Cl deriv.,  $b_{780}$  284°, m. 98°; 4-Br deriv.,  $b_{750}$  290-3°, m. 108-9°; 4-I deriv., m. 125-6°; 3-I deriv., m. 159-61°. From these anhydrides mixts. of isomeric phthaleins were obtained except in the case of the 3-I deriv., which *phthalein* m. 252-4°. The compn. of the mixts. was established by

alkali fusion and identification of the  $\text{HOC}_6\text{H}_4\text{CO}_2\text{H}$  formed. Crystallographic data are recorded for the 4-substituted anhydrides.

**Absorption spectra of some phthaleins of the trihydroxyphenols.** R. C. GIBBS AND C. V. SHAPIRO. *J. Am. Chem. Soc.* 51, 1755-66(1929).—Data and curves are presented on the absorption spectra of the benzein, phthalein and sulfonephthalein of 1,2,3- $\text{C}_6\text{H}_3(\text{OH})_3$ , the phthalein and sulfonephthalein of 1,2,4- $\text{C}_6\text{H}_3(\text{OH})_3$  and the sulfonephthalein of 1,3,5- $\text{C}_6\text{H}_3(\text{OH})_3$ . Correlations are drawn with data previously obtained for phthaleins of  $\text{PhOH}$  and  $\text{C}_6\text{H}_4(\text{OH})_2$ . The effect on the chem. properties and absorption spectra of the phthaleins, due to the introduction of HO groups, is discussed. Gallein, which is colored in both the solid state and in neutral soln., is shown to be primarily lactoid in structure, but probably in equil. with a small amt. of the quinoid modification. The unusual behavior of 1,2,4- $\text{C}_6\text{H}_3(\text{OH})_3$  in weakly alk. solns., both as regards its absorption and fluorescence, is described and a possible explanation is advanced.

**Compounds of phthaleins with metals.** E. BUREŠ, J. BERGAUER AND A. KRÁČÍK. *Časopis Českoslov. Lékárnictva* 8, 180-3(1928).—The condensation of fluorescein with  $\text{Hg}^{++}$  salts yielded a product contg. 18.37% of Hg; as this is slightly below the theoretical value, it is probable that some complex compds. were formed. A similar condensation product of dibromofluorescein contained 16.41% of Hg, or nearly the theoretical proportion. With phenolphthalein the Hg entered the mol. Na, K, Li and Ba salts of the mercurialized phthaleins were prep'd. Condensations were also made of phthaleins with Ag, Bi and several other metals.

**Absorption spectra of some halogenated fluoresceins.** R. C. GIBBS AND C. V. SHAPIRO. *J. Am. Chem. Soc.* 51, 1769-73(1929).—Absorption curves and data are presented for the di-Br, tetra-Br and tetra-Cl derivs. of fluorescein. Halogenation of the phenolic groups appears to bring into action 2 opposing forces: (1) a tendency to decrease the intensity which can be ascribed to the intrinsic nature of the halogen, (2) a tendency to increase the intensity, which may be ascribed to the mass action of the halogen.

**Ethyl- and hexylfluorescein. Their dibromo and monomercure derivatives.** REUBEN B. SANDIN AND JOHN W. SUTHERLAND. *J. Am. Chem. Soc.* 51, 1773-5(1929). Ethylresorcinol and  $\text{C}_6\text{H}_4(\text{CO})_2\text{O}$  give *ethylfluorescein*, dark brown by pptn. with HCl from hot NaOH soln., or boiling with HCl, brown by slow evapn. of the EtOH soln. and yellow by adding AcOH to the cold NaOH soln.; *di-Br deriv.*, reddish brown, *Hg deriv.*, red. *Hexylfluorescein*, brown by adding HCl to boiling NaOH soln., yellow by adding AcOH to cold NaOH soln.; *di-Br deriv.*, reddish brown; *Hg deriv.*, reddish brown. The yellow form of each is given the lactoid, the brown form, the *p*-quinoid structure.

**Derivatives of binaphthylene dioxide.** I. A. CORBELLINI AND F. VIETTI. *Gazz. chim. ital.* 58, 766-74(1928).—A study of the method of prep'n. of binaphthylene dioxide (I) of Pummerer, Prell and Rieche (cf. C. A. 21, 405) showed that the 2nd method can be simplified and the yield increased by eliminating the  $\text{PhNO}_2$ , increasing the CuO and the temp. Further expts. show that I reacts very easily with various reagents such as Cl, Br and  $\text{HNO}_3$ , and condenses easily with  $\text{BzCl}$  and  $\text{C}_6\text{H}_4(\text{CO})_2\text{O}$ . In the present paper some disubstituted and tetrasubstituted derivs. are described.  $\beta$ -Binaphthol (286 g.) and CuO (336 g.) heated 4-5 hrs. at  $300-10^\circ$  with const. agitation (the end of the reaction being when the product mixed with dil. NaOH and filtered does not give a ppt. with acids), pulverized, extd. with PhCl (100 g. per 15 g. of product), the ext. decolorized with bone black, concd., cooled and the ppt. recrystd. from  $\text{C}_6\text{H}_6$ , yields 84% of I, m.  $240^\circ$ . Mixts. of concd. HCl (30 cc.) and AcOH (180 cc.) and of 34%  $\text{H}_2\text{O}_2$  (7 g.) and AcOH (90 cc.) added simultaneously during 1.5 hr. to I (10 g.) in  $\text{PhNO}_2$  (400 cc.) on a water bath, let stand overnight, filtered, washed with EtOH and the residue recrystd. from  $\text{PhNO}_2$ , yields a *di-Cl deriv.* (II),  $\text{C}_{20}\text{H}_8\text{O}_2\text{Cl}_2$ , of I, yellow, m.  $259^\circ$ , gives a violet soln. in concd.  $\text{H}_2\text{SO}_4$ , from which I is reprecip. by diln. with water. This method of chlorination (cf. Zinke and Pongratz, C. A. 19, 1568) must be controlled so that the proportion of Cl to I is exact, otherwise a slight excess forms compds. with more Cl. Like chlorination, bromination must be carried out with the exact proportion of Br. Br (11.33 g.) in  $\text{CS}_2$  (50 cc.) added slowly to I (10 g.) in  $\text{CS}_2$  (200 cc.), agitated for some time, filtered and the residue recrystd. from PhCl, yields a *di-Br deriv.*,  $\text{C}_{20}\text{H}_8\text{O}_2\text{Br}_2$  of I, light yellow, m.  $277^\circ$ , which with concd.  $\text{H}_2\text{SO}_4$  behaves like II. Brominated with an excess of Br, I yields a *tetra-Br deriv.*,  $\text{C}_{20}\text{H}_4\text{O}_2\text{Br}_4$ , of I, light yellow, m.  $349-51^\circ$ , gives a violet-blue soln. in concd.  $\text{H}_2\text{SO}_4$ . A tetranitro and a hexanitro deriv. of I are already known (cf. Fr. Pat. 600,390(1925)). I (5 g.) in  $\text{CCl}_4$  (80 cc.) agitated with  $\text{HNO}_3$  (d. 1.2) (100 cc.), let stand several hrs., dild. with water, the  $\text{CCl}_4$  distd., filtered

and the residue recrystd. from  $\text{PhNO}_2$ , yields a *dinitro deriv.* (III),  $\text{C}_{20}\text{H}_8\text{O}_2(\text{NO}_2)_2$ , of I, dark red. III dissolved in cold concd.  $\text{H}_2\text{SO}_4$  (violet soln.), pptd. by addn. of water, the ppt. dissolved in dil.  $\text{NaOH}$ ,  $\text{Na}_2\text{S}_2\text{O}_4$  (or  $\text{SnCl}_2$  and  $\text{HCl}$ ) added, yields a yellow compd., which is unstable in air and which was not identified.  $\text{BzCl}$  (5 g.) and then  $\text{AlCl}_3$  (5 g.) added slowly to I (5 g.) in  $\text{CS}_2$  (100 cc.), let stand overnight, heated several hrs. on a water bath, the  $\text{CS}_2$  distd., the residue decompd. with  $\text{HCl}$ , boiled, filtered and the residue recrystd. from  $\text{PhCl}$ , yields a *dibenzoyl deriv.* (IV),  $\text{C}_{20}\text{H}_8\text{O}_2\text{Bz}_2$ , of I, yellow, m.  $318.5^\circ$ , gives in cold concd.  $\text{H}_2\text{SO}_4$  a violet-blue soln. which turns brown when heated, and from which IV is repptd. on diln. with water. IV sublimes with partial decompn. Condensation of I in  $\text{C}_6\text{H}_6$  was carried out by a method similar to that used by Heller for hydrocarbons (cf. *C. A.* 3, 318). I (5 g.) fused with  $\text{C}_6\text{H}_5(\text{CO})_2\text{O}$  (2.6 g.) (avoiding sublimation), pulverized, suspended in anhyd.  $\text{C}_6\text{H}_6$  (200 cc.),  $\text{AlCl}_3$  (5 g.) added slowly, heated several hrs. on a water bath (until  $\text{HCl}$  is no longer evolved), the  $\text{C}_6\text{H}_6$  distd., water added (which forms  $(\text{C}_{20}\text{H}_8\text{O}_2\text{COC}_6\text{H}_4\text{CO}_2)_3\text{Al}$ ), treated with  $\text{NaOH}$ , filtered,  $\text{HCl}$  added to the filtrate and the ppt. recrystd. from  $\text{PhCl}$ , yields a *monophthaloyl deriv.*,  $\text{C}_{22}\text{H}_{14}\text{O}_6$ , of I, orange, decomp. at  $350^\circ$ , gives a green soln. in concd.  $\text{H}_2\text{SO}_4$ . Proceeding as before, only with twice as much  $\text{C}_6\text{H}_5(\text{CO})_2\text{O}$  and  $\text{AlCl}_3$ , and recrystg. the product from nitrotoluene, there is obtained a *diphthaloyl deriv.*,  $\text{C}_{20}\text{H}_8\text{O}_2(\text{COC}_6\text{H}_4\text{CO}_2\text{H})_2$ , of I, yellow, decomp. at  $350^\circ$ , gives a green soln. in concd.  $\text{H}_2\text{SO}_4$ . The orientation of the substituents in the derivs. of I is being studied.

C. C. DAVIS

**Action of phthalic anhydride on aminoazo derivatives.** G. B. CRIPPA AND P. GALIMBERTI (WITH A. BORRONI). *Gazz. chim. ital.* 58, 731–8 (1928).—An investigation under way necessitated protecting the  $\text{NH}_2$  group of phenylazo- $\beta$ -naphthylamine (I), and so the tendency of  $\text{C}_6\text{H}_5(\text{CO})_2\text{O}$  (II) to pass to the corresponding phthalimide was studied. Though this reaction was considered certain, the condensation product of I and II showed none of the phys. and chem. properties of compds. contg. a N group, and therefore the reaction proceeded differently from that leading to naphthylphthalimides (cf. *Gazz. chim. ital.* 15, 479 (1885); Lesser, *C. A.* 8, 661). The action of II on the 2 isomers of arylazonaphthylamines, where the  $\text{NH}_2$  group is in positions 2 and 4, resp., was, therefore, studied. The results show that the 1-arylazo-4-aminonaphthalenes form the corresponding 1-arylazo-4-phthalimidonaphthalenes (III),  $\text{C}_{10}\text{H}_6(\text{N}:\text{NAr})-\text{N}(\text{CO})_2\text{C}_6\text{H}_4$ , which in turn form the arylazonaphthylphthalamic acids (IV),  $\text{C}_{10}\text{H}_6(\text{N}:\text{NAr})\text{NHCOC}_6\text{H}_4\text{CO}_2\text{H}$ , whereas the 1-aryl-2-aminonaphthalenes lose by reduction the entire aryl-N group, forming  $\beta$ -naphthylphthalimides. The mechanism of this latter reaction is uncertain. II (2 g.) and 1,4- $\text{C}_{10}\text{H}_6(\text{N}:\text{NPh})\text{NH}_2$  (2.5 g.) heated 1 hr. at  $170^\circ$  and the product recrystd. repeatedly from  $\text{AcOH}$  and xylene, yields 1-phenylazo-4-phthalimidonaphthalene (V), orange-yellow, m.  $219^\circ$ . Aq. 30%  $\text{KOH}$  (70 cc.) boiled with V (1 g.) for 2 hrs., and the product recrystd. from water or  $\text{C}_6\text{H}_6$ , yields K 1-phenylazonaphthyl-4-phthalimide (VI), red. Ba salt. VI dissolved in hot  $\text{AcOH}$  and cooled ppts. 1-phenylazonaphthyl-4-phthalimidic acid (VII), green with golden reflection; its soln. in  $\text{AcOH}$  is an intense violet-red. When heated, VII loses  $\text{H}_2\text{O}$ , forming V. In dil.  $\text{AcOH}$ , VII dyes animal fibers orange-red. Likewise was obtained from 1-[o-tolylazo]-4-aminonaphthalene, after crystn. from  $\text{AcOH}$ , 1-[o-tolylazo]-4-phthalimidonaphthalene, orange-red, m.  $194^\circ$ , and from the *m*-compd., with crystn. from  $\text{AcOH}$ , the 1-*m*-tolylazo deriv., intense red, m.  $198^\circ$ . II and 1-[*p*-bromophenylazo]-4-aminonaphthalene heated at  $180^\circ$ , and the product crystd. from  $\text{AcOH}$  and xylene, yields 1-[*p*-bromophenylazo]-4-phthalimidonaphthalene, orange, m.  $243^\circ$ . Similarly, with crystn. from xylene and  $\text{AcOH}$ , 1-[*p*-acetylphenylazo]-4-aminonaphthalene (VIII) forms 1-[*p*-acetylphenylazo]-4-phthalimidonaphthalene, dark lustrous red, m.  $249^\circ$ . VIII, not described heretofore, was prepd. by diazotizing *p*- $\text{H}_2\text{NC}_6\text{H}_4\text{COME}$  in  $\text{HCl}$ , coupling with  $\alpha\text{-C}_{10}\text{H}_7\text{NH}_2$ , neutralizing with  $\text{NH}_4\text{OH}$  and crystg. from  $\text{EtOH}$ . It is brown-red and m.  $197^\circ$ . II (3 g.) heated at  $195^\circ$  with K phenylazo-4-naphthylamine-*p*-sulfonate (2 g.) and the product recrystd. from  $\text{AcOH}$  and then water, yields K 4-phthalimidonaphthyl-1-azophenyl-*p*-sulfonate, yellow, decomp. without fusion.  $\alpha$ -Naphthylazo-4-amino- $\alpha$ -naphthalene and II from (crystn. form  $\text{AcOH}$  and xylene) 1-naphthylazo-4-phthalimidonaphthalene, lustrous orange-yellow, m.  $211^\circ$ . Similarly is obtained  $\alpha$ -naphthylazo-4-phthalimido- $\beta$ -naphthalene, orange, m.  $257^\circ$ . I (2.5 g.) and II (2 g.) heated for 1 hr. at  $150\text{--}5^\circ$ , the product recrystd. repeatedly from xylene and  $\text{AcOH}$ , and finally sublimed, yields  $\beta\text{-C}_{10}\text{H}_7\text{N}(\text{CO})_2\text{C}_6\text{H}_4$ . A small quantity of  $\beta$ -naphthylazo- $\beta$ -naphthylamine was isolated as a by-product. The same reaction with other  $\alpha$ -aminoazo compds., e. g., *p*-acetylphenylazo- $\beta$ -naphthylamine and  $\alpha$ -naphthylazo- $\beta$ -naphthylamine, always led to the formation of  $\beta\text{-C}_{10}\text{H}_7\text{N}(\text{CO})_2\text{C}_6\text{H}_4$ , showing that this reaction is general for  $\alpha$ -aminoazo compds.

C. C. DAVIS

**Metallic complexes in the series of *o*-amino and *o*-hydroxyazo derivatives.** G. B. CRIPPA (WITH F. VICINI, G. LEVI AND A. MANGANO). *Gazz. chim. ital.* **58**, 716-26 (1928).—Expts. on compds. of the type  $[C_{10}H_6(N:NAr)X]_2M$ , where Ar is an aryl radical, X is  $NH_2$  or OH and M is Cu, Ni or Co (cf. *C. A.* **22**, 415) were continued, efforts being made to det. whether various substituents, particularly negative ones, in the aryl nucleus have an influence on the formation of these complexes, and whether combination with the metal is still possible when H is replaced by oxyazo compds. In the present paper the ammoniacal metal sulfate was made to react with the arylazo-naphthylamine or arylazonaphthol contg. the OH,  $NO_2$ , Ac and  $SO_3H$  groups. Phenolic OH has an unfavorable influence on the reaction, the complexes derived from *p*-hydroxyphenylazo- $\beta$ -naphthol forming with difficulty, and the analogous compds. from *p*-hydroxyphenylazo- $\beta$ -naphthylamine not being obtained. On the other hand, the Ac and  $NO_2$  groups do not impede the formation, the reaction proceeding easily except with Co.  $SO_3H$  behaves at times in a way which does not admit of any general conclusion. Thus among the sulfonated aminoazo derivs. the properties of the cupric complex differed from the analogous complexes of simple aminoazo derivs., the Cu being united as in the other cases with 2 mols. of the aminoazo deriv. but the structure being complicated by the adherence of *n*  $NH_2$  groups in an unstable condition. Thus the K salt of phenylazo- $\beta$ -naphthylamine is  $[1,2-C_{10}H_6(N:N(1')C_6H_4(4')SO_3)NH_2]_2Cu \cdot nNH_3 \cdot K_n$ , while phenylazo- $\beta$ -naphthol-*p*-sulfonic acid leads to a complex with no coordinated  $NH_2$  groups and which is an  $NH_4$  salt:  $[1,2-C_{10}H_6(N:N(1')C_6H_4(4')SO_3)OH]_2Cu(NH_4)_2$ . Attempts to prep. the corresponding Ni complex led to compds. of various colors which are unstable in light and air and which could not be obtained with const. compns. The 2nd part of the investigation was concerned with the mol. configuration of the new compds. Their general properties and the similarity between the derivs. of the azonaphthylamine and azonaphthol series, in the former of which the complexes are formed by direct action of the metallic powder in an inert medium, indicates that the org. mol. participates in its entirety in the coordination of the complexes. A discussion of the possible structures leads to the conclusion that the formula  $[C_{10}H_6(N:NAr)X]_2M$  (*loc. cit.*) is the most likely one if the metal atom is considered to be in the center and united to 2 org. mols. by partial valences alone. Such a configuration is similar to that suggested by Kunz and Stuhlinger (*C. A.* **20**, 414) and K and Kress (*C. A.* **21**, 1658) for a Cu-indigo complex. In this latter connection the property of aminocupric complexes of being easily transformed into the corresponding triazoles can be explained by the following structure:

At the instant of disintegration of the complex and of dehydrogenation of the aminoazo deriv., the N double bond is weakened, and a new bond, which is of the ordinary type rather than covalent, is formed between the 2 N atoms. For the prepn. of the complexes, the azo deriv. was treated with the ammoniacal metal sulfate (method A) or with the finely powd. metal (method B). The following data show the compds. prepd. (A) or (B) designating which of the methods above was used. *Nickelo-di-p-hydroxyphenylazo- $\beta$ -naphthol* (A), dark brown, could not be crystd., does not m. up to  $300^\circ$ , decompd. by AcOH, stable in alkalis. *Cupri-di-p-hydroxyphenylazo- $\beta$ -naphthol* (A), dark maroon-red, could not be crystd., m.  $245^\circ$ . No corresponding Co salt could be obtained. From *p*-hydroxyphenylazo- $\beta$ -naphthylamine, no metal complexes could be obtained, either by (A) or (B). *Nickelo-di-p-acetylphenylazo- $\beta$ -naphthol* (A), 75% yield, brown-green, does not m. up to  $300^\circ$ . *Cupri-di-p-acetylphenylazo- $\beta$ -naphthol* (A), 35% yield, dark brick-red, does not m. up to  $300^\circ$ . *Cobalto-di-p-acetylphenylazo- $\beta$ -naphthol* (A) in presence of  $NH_4Cl$ , black powder, m.  $275^\circ$ . *Cupri-di-p-acetylphenylazo- $\beta$ -naphthylamine* (A), black, m.  $210^\circ$ . The corresponding Ni and Co derivs., prepd. by (B), have already been described (cf. Crippa, *C. A.* **21**, 1810). *Nickelo-di-o-nitrophenylazo- $\beta$ -naphthol* (A), 50% yield, greenish black, m.  $294^\circ$ . *Cupri-di-o-nitrophenylazo- $\beta$ -naphthol* (A), 50% yield, brown-green, m.  $263^\circ$ . The corresponding Co salt could not be obtained. *Ni-di-m-nitrophenylazo- $\beta$ -naphthol* (A), 60% yield, dark

green, does not m. up to 300°. *Cupri-di-m-nitrophenylazo-β-naphthol* (A), 80% yield, maroon-red, m. 295°. No corresponding Co salt was obtained. *Nickelo-di-p-nitrophenylazo-β-naphthol* (A), 80% yield, dark gray, does not m. up to 300°. *Cupri-di-p-nitrophenylazo-β-naphthol* (A), 80% yield, coffee-color, does not m. up to 300°. No corresponding Co salt was obtained. *Nickelo-di-o-nitrophenylazo-β-naphthylamine* (A), 35% yield, greenish black, m. 250°. The formation of the corresponding Cu salt was uncertain, though a dark green compd., m. 260°, was obtained. By (B) no Co complex could be isolated in a pure form. *Nickelo-di-m-nitrophenylazo-β-naphthylamine* (A), 60% yield, greenish black, m. 258°. *Cupri-di-m-nitrophenylazo-β-naphthylamine* (A), 45% yield, brown, m. 209°. *Cobalto-di-m-nitrophenylazo-β-naphthylamine* (B), very dark green, microcryst., does not m. up to 300°. *Nickelo-di-p-nitrophenylazo-β-naphthylamine* (A), 40% yield, dark green, microcryst., m. 290°. *Cupri-di-p-nitrophenylazo-β-naphthylamine* (A), 60% yield, maroon with golden reflection, m. 236°. *Cobalto-di-p-nitrophenylazo-β-naphthylamine* (A), very low yield, green, does not m. up to 300°. By method (A), *p*-nitrophenylazo-β-naphthylaminesulfonic acid did not form compds. which could be isolated in definite form, but 2 g. suspended in boiling EtOH (40 cc.), boiled 1 hr. with NiSO<sub>4</sub> (6 g.) in dil. NH<sub>4</sub>OH (10 cc. of NH<sub>4</sub>OH + 6 cc. H<sub>2</sub>O), filtered hot, and the filtrate let stand, yields the compd. [1,2-C<sub>10</sub>H<sub>6</sub>(N:N(1')-C<sub>6</sub>H<sub>4</sub>(4')SO<sub>3</sub>)OH]<sub>2</sub>Ni, greenish black. By method (A) there was also obtained the compd. ([C<sub>10</sub>H<sub>6</sub>(N:NC<sub>6</sub>H<sub>4</sub>SO<sub>3</sub>)OH]<sub>2</sub>Cu)(NH<sub>4</sub>)<sub>2</sub> brown, evolves NH<sub>3</sub> at 120–50° or in aq. KOH. With Co the results were uncertain. With 1,2-H<sub>2</sub>NC<sub>10</sub>H<sub>6</sub>N:NC<sub>6</sub>H<sub>4</sub>SO<sub>3</sub>K-*p*, no Ni or Co complex was obtained, but by method (A) the compd. ([C<sub>10</sub>H<sub>6</sub>(N:NC<sub>6</sub>H<sub>4</sub>SO<sub>3</sub>)(NH<sub>2</sub>)<sub>2</sub>Cu.4NH<sub>3</sub>)K<sub>2</sub> evolves NH<sub>3</sub> when gently warmed; when boiled in water for a long time it forms K *N*-phenyl-1,2-naphthotriazolesulfonate (cf. *Ber.* 27, 2375 (1894); *Ger. Pat.* 107,498). In a similar way was obtained the compd. ([C<sub>10</sub>H<sub>6</sub>(N:NC<sub>6</sub>H<sub>4</sub>SO<sub>3</sub>)(NH<sub>2</sub>)<sub>2</sub>Cu.4NH<sub>3</sub>)Na<sub>2</sub>. On the other hand, 1,2-H<sub>2</sub>NC<sub>10</sub>H<sub>6</sub>N:NC<sub>6</sub>H<sub>4</sub>SO<sub>3</sub>H-*p*, CuSO<sub>4</sub> and excess NH<sub>4</sub>OH did not form the corresponding complex, but the triazolesulfonic acid. The ammoniacal sulfates of the metals which formed the foregoing types of complexes were added to Me ether of phenylazo-β-naphthol and to the Me and Et ethers of *p*-acetylphenylazo-β-naphthol, but in no case was it possible to isolate a complex. *p*-Acetylphenylazo-β-naphthol, which has not been described heretofore, was prepd. by coupling a *p*-aminoacetophenonediazonium salt with phenylazo-β-naphthol in aq. NaOH. It is red with golden reflection, and m. 180°; *oxime*, bright red, m. 234–5°; *phenylhydrazone*, maroon, m. 165°; *semicarbazone*, maroon with green reflection, does not m. up to 300°. *Me ether of p*-acetylphenylazo-β-naphthol, by the action of Me<sub>2</sub>SO<sub>4</sub>, dark red, m. 134–5°; *oxime*, red, m. 250°; *phenylhydrazone*, red, m. 87–8°; *semicarbazone*, red, m. 210°. *Et ether of p*-acetylphenylazo-β-naphthol, by the action of Et<sub>2</sub>SO<sub>4</sub>, ruby-red, m. 102°; *oxime*, red, 161–2°; *phenylhydrazone*, dark red, m. 64°; *semicarbazone*, brick-red, m. 190°.

Constitutional influences on the conversion of azonaphthols into their azosulfites and their bearing on the structure of  $\alpha$ - and  $\beta$ -naphthol. ALBERT T. KING. *J. Chem. Soc.* 1929, 601–9.—The conversion of azonaphthols into their azosulfites is of special significance in dyes derived from them, since this reaction underlies their degree of fastness to SO<sub>2</sub> on alk. fabric as distinguished from the ordinary stoving test with excess of SO<sub>2</sub>. The difference in activity, notably with respect to the "active range" of alkyl on wool fabric, is further considered in the present paper, more particularly with regard to the positional effect of SO<sub>3</sub>H groups. With the naphthol nucleus unsubstituted, the azo- $\alpha$ -naphthol bisulfite compds. form fairly readily, although less so than the corresponding  $\beta$ -naphthol derivs., e. g., *p*-sulfobenzeneazo- $\alpha$ -naphthol reacts rather less readily than *p*-sulfobenzeneazo- $\beta$ -naphthol, and 4-sulfo- $\alpha$ -naphthaleneazo- $\alpha$ -naphthol (acid brown R) distinctly less readily than the corresponding  $\beta$ -naphthol compd. (fast red A). No close comparison of constitutional influences can be drawn here, since the coupling of  $\beta$ -naphthol derivs. occurs at the *o*-position to the HO group, while with the above  $\alpha$ -naphthol compds. the coupling is at the *p*-position to the HO group. When the naphthol component is sulfonated, however, so that the coupling is in the *o*-position for both  $\alpha$ - and  $\beta$ -naphthol, a wide divergence in reactivity appears. The azo- $\beta$ -naphtholsulfonic acids show no falling off in reactivity; rather, owing to the increasing soly. accompanying introduction of SO<sub>3</sub>H groups, conversion into the azosulfite becomes, if anything, more readily effected. The well-characterized sulfites of a no. of azo- $\beta$ -naphtholsulfonic acids are recorded in the exptl. part. No example has so far been found where an azo compd. with a  $\beta$ -naphthol residue has failed to form a bisulfite deriv. On the other hand, azo derivs. of  $\alpha$ -naphthol show a striking loss of reactivity with introduction of SO<sub>3</sub>H groups, the only case of sulfite formation observed being with a SO<sub>3</sub>H group in the 5-position and then only when the azo deriv.

is formed from an unsulfonated diazo compd., e. g.,  $\alpha$ -naphthaleneazo- $\alpha$ -naphthol-5-sulfonic acid (Double Ponceau) yields the azosulfite, but the corresponding 4-sulfo- $\alpha$ -naphthaleneazo- $\alpha$ -naphthol-5-sulfonic acid (Fast Red V.R.) merely undergoes slow fission, without any azosulfite formation occurring. The non-reactivity of the following dyes illustrates the general inhibition with a sulfonated  $\alpha$ -naphthol component:  $\alpha$ -naphthaleneazo- $\alpha$ -naphthol-4,8-disulfonic acid (Azo Bordeaux, Bayer),  $\alpha$ -naphthaleneazo- $\alpha$ -naphthol-3,6-disulfonic acid (Benzyl Bordeaux B, Clayton Aniline Co.), 4-sulfo- $\alpha$ -naphthaleneazo- $\alpha$ -naphthol-4-sulfonic acid (Carmoisine, Sandoz), 4-sulfo- $\alpha$ -naphthaleneazo- $\alpha$ -naphthol-5-sulfonic acid (Fast Red V.R., Bayer), 6-sulfo- $\beta$ -naphthaleneazo- $\alpha$ -naphthol-4-sulfonic acid (Brilliant Ponceau 4R, Bayer). With regard to the actual compn. of the bisulfite compds., the fission of the azo linkage which usually occurs under prolonged treatment of azo dyes of the  $\alpha$ -naphthol type with bisulfite is of significance. The analyses recorded in the exptl. part are all lower than are required by the dehydrated form, but show generally a slightly higher content of  $\text{SO}_2$  than is required for the hydrazone form. The difficulty both of purifying and of accurately analyzing these compds. makes such evidence untrustworthy as to whether the water mol. is split off or not. The marked difference in color, however, between the dye and its bisulfite compd. suggests a modified N linking, and this view is supported by the fact that the N link in the bisulfite product is stable to further action of bisulfite, whereas the azo link is reduced. Consequently, the bisulfite compds. are to be regarded as retaining the additive structure, without reversion to the azo linking by loss of water. Among the compds. prepd. and characterized were: *Na benzeneazo-6-sulfo- $\beta$ -naphthyl sulfite*,  $\text{C}_{16}\text{H}_{10}\text{O}_4\text{N}_2\text{S}_2\text{Na}_2$  (bisulfite compd. of Croceine Orange, Bayer), canary-yellow powder on rubbing; *Na  $\alpha$ -naphthaleneazo-6-sulfo- $\beta$ -naphthyl sulfite*,  $\text{C}_{20}\text{H}_{12}\text{O}_6\text{N}_2\text{S}_2\text{Na}_2 \cdot \text{H}_2\text{O}$  (bisulfite compd. of Fast Red B, Bayer), bronze-brown cryst. product on drying; *Na 4-sulfo- $\alpha$ -naphthaleneazo-6-sulfo- $\beta$ -naphthyl sulfite*,  $\text{C}_{20}\text{H}_{11}\text{O}_8\text{N}_2\text{S}_4\text{Na}_3 \cdot \text{H}_2\text{O}$  (bisulfite compd. of Fast Red E.A.S., Brit. Dyestuffs Corp.), bright orange cryst. powder; *Na benzeneazo-3,6-disulfo- $\beta$ -naphthyl sulfite*,  $\text{C}_{16}\text{H}_9\text{O}_6\text{N}_2\text{S}_4\text{Na}_3 \cdot \text{H}_2\text{O}$  (bisulfite compd. of Acid Orange R, Brit. Dyestuffs Corp.), dull yellow cryst. powder; *Na m-xyleneazo-3,6-disulfo- $\beta$ -naphthyl sulfite*,  $\text{C}_{18}\text{H}_{13}\text{O}_6\text{N}_2\text{S}_4\text{Na}_3 \cdot \text{H}_2\text{O}$  (bisulfite compd. of Ponceau 2RE, Geigy) buff-yellow cryst. powder; *Na o-carboxybenzeneazo-3,6-disulfo- $\beta$ -naphthyl sulfite*,  $\text{C}_{17}\text{H}_9\text{O}_{11}\text{N}_2\text{S}_4\text{Na}_4 \cdot \text{H}_2\text{O}$  (Solochrome Red B, Brit. Dyestuffs Corp.), dull orange cryst. powder; *Na  $\alpha$ -naphthaleneazo-3,6-disulfo- $\beta$ -naphthyl sulfite*,  $\text{C}_{20}\text{H}_{11}\text{O}_8\text{N}_2\text{S}_4\text{Na}_3 \cdot \text{H}_2\text{O}$  (bisulfite compd. of Bordeaux B, Sandoz), brick-red cryst. powder; *Na 4-sulfo- $\alpha$ -naphthaleneazo-3,6-disulfo- $\alpha$ -naphthyl sulfite*,  $\text{C}_{20}\text{H}_{10}\text{O}_{12}\text{N}_2\text{S}_4\text{Na}_4 \cdot \text{H}_2\text{O}$  (bisulfite compd. of Azo Rubine S, Sandoz), orange-brown cryst. powder; *Na 4-sulfo- $\alpha$ -naphthaleneazo-6,8-disulfo- $\beta$ -naphthyl sulfite*,  $\text{C}_{20}\text{H}_{10}\text{O}_{12}\text{N}_2\text{S}_4\text{Na}_4 \cdot \text{H}_2\text{O}$  (bisulfite compd. of Scarlet 5/0, Brit. Dyestuffs Corp.), dull yellow cryst. powder; *Na 4-sulfo- $\alpha$ -naphthaleneazo-3,6,8-trisulfo- $\beta$ -naphthyl sulfite*,  $\text{C}_{20}\text{H}_9\text{O}_{15}\text{N}_2\text{S}_6\text{Na}_5 \cdot \text{H}_2\text{O}$  (bisulfite compd. of Ponceau 6R, Bayer), deep orange cryst. powder deliquescent in air; *Na  $\alpha$ -naphthaleneazo-6-sulfo- $\alpha$ -naphthyl sulfite*,  $\text{C}_{20}\text{H}_{12}\text{O}_6\text{N}_2\text{S}_2\text{Na}_2 \cdot \text{H}_2\text{O}$  (bisulfite compd. of Double Ponceau 2R, Bayer), orange cryst. powder.

Chemistry of the Kolbe-Schmitt syntheses. The action of carbon dioxide on sodium 2-naphtholate. ERW. SCHWENK WITH M. KNOB AND H. STEIN. *Chem.-Ztg* 53, 297-9, 333-6 (1929).—When dry  $\beta$ - $\text{C}_{10}\text{H}_7\text{ONa}$  (prepd. by dissolving Na in  $\beta$ - $\text{C}_{10}\text{H}_7\text{OH}$  in boiling anhyd. solvent naphtha, b. p.  $160^\circ$ , cooled with ice, filtered, washed with ligroin, dried *in vacuo* over  $\text{H}_2\text{SO}_4$  and paraffin) in a glass tube is treated at  $18$ – $20^\circ$  with  $\text{CO}_2$  (dried with  $\text{H}_2\text{SO}_4$ ,  $\text{CaCl}_2$  and then  $\text{P}_2\text{O}_5$ ) at 10 mm.  $\text{H}_2\text{O}$  pressure, nearly 1 mol. (95%) is absorbed forming  $\text{C}_{10}\text{H}_7\text{OCO}_2\text{Na}$  (I); when I is heated to  $120$ – $30^\circ$  for 6 hrs. in a sealed tube it forms  $\text{CO}_2$ ,  $\beta$ - $\text{C}_{10}\text{H}_7\text{OH}$  and *Na  $\beta$ -hydroxy- $\alpha$ -naphthoate*,  $\text{C}_{10}\text{H}_6(\text{OH})\text{CO}_2\text{Na}$  (II); when I is heated to  $80^\circ$  it forms  $\beta$ - $\text{C}_{10}\text{H}_7\text{ONa}$  and  $\text{CO}_2$ ; when II is heated *in vacuo* (8 mm.) for 3 hrs. at  $180^\circ$  it forms  $\text{CO}_2$  and  $\beta$ - $\text{C}_{10}\text{H}_7\text{ONa}$ ; when II is heated *in vacuo* for 6 hrs. at  $280^\circ$  it forms  $\beta$ - $\text{C}_{10}\text{H}_7\text{OH}$  and *Na 2-hydroxy-3-naphthoate* (III); III is not decompd. by heating to  $280^\circ$ . From this it is concluded that the mechanism of the reaction is as follows:

thus explaining the remarkable rearrangement of the  $\text{CO}_2\text{H}$  group from position 1 to position 3.  $\beta$ , $\alpha$ - $\text{C}_{10}\text{H}_6(\text{OH})\text{CO}_2\text{K}$  is stable at temps. up to  $200^\circ$  and (unlike the

corresponding Na salt) is not converted to the salt of 2,3- $C_{10}H_6(OH)CO_2H$  unless heated to at least 230° when only traces are formed. Contrary to the statements in D. R. P. 436,524, no *K* 2-hydroxy-6-naphthoate was obtained at 260, 280, or 300°. These negative results may be due to the small amts. of starting material (5 g.) not furnishing a sufficient amt. for identification. These results confirm the theories of the mechanism of similar reaction as expressed by Tijmstra and Eggink (cf. *Ber.* 39, 14(1906)) and Davies (cf. *C. A.* 23, 2507).

N. A. LANGE

**Preparation of aminonaphthols.** WILSON F. BROWN, JOHN C. HEBDEN AND JAMES R. WITHROW, *J. Am. Chem. Soc.* 51, 1766-9(1929).—1,7- $C_{10}H_6(NH_2)OH$  was prepd. in good yield and of good quality from 1,7- $C_{10}H_6(NH_2)SO_3H$  by NaOH fusion, at much higher temps. than were given by Cassella (Ger. Pat. 69,458) and was isolated both as the base and as the HCl salt. The mixt. was heated at 265-75° for 1 hr., at 305° for 5 mins. and then cooled to 200°. 1,6- $C_{10}H_6(NH_2)OH$  was prepd. similarly from 1,6- $C_{10}H_6(NH_2)SO_3H$  and was purified by extg. with 7.5% HCl and pptg. with  $NH_4OH$  or by repeatedly crystg. from hot  $H_2O$ ; it m. 190.6° (cor.); the picrate m. 170° (cor.); acetylation was unsuccessful.

C. J. WEST

**Mercuration of naphthalic acids.** G. J. LEUCK, R. P. PERKINS AND FRANK C. WHITMORE, *J. Am. Chem. Soc.* 51, 1831-6(1929).—Naphthalic acid (50.5 g.) in 1.2 l.  $H_2O$  and 31 g. NaOH, treated with 55 g.  $HgO$  in 150 cc.  $H_2O$  and 40 cc. glacial AcOH and refluxed 98 hrs., gives 97.6% of anhydro-8-hydroxymercuri-1-naphthoic acid; evapg. an alk. soln. gives Na 8-hydroxymercuri-1-naphthoate; heating 46.5 g. of the Na salt in 500 cc.  $H_2O$  with 200 cc. concd. HCl gives 87% of the 1-naphthoic acid, m. 162°. 3-Nitronaphthalic anhydride (304 g.) gives 505 g. (97%) of a mixt. of anhydro-3-nitro-8-hydroxymercuri-1-naphthoic acid and the corresponding 6- $NO_2$  compd.(I), which could not be purified. Evapg. the alk. soln. of I gives Na 3-nitro-8-hydroxymercuri-1-naphthoate, yellow. Refluxing with an excess of EtOH-NaI gives Na 8-mercuribis-3-nitro-1-naphthoate. Heating I with HCl for 2 hrs. gives 63% of 3-nitro-1-naphthoic acid (II), m. 270.5-1.5°, and 13% of the 6- $NO_2$  deriv.(III), m. 227-7.5°. II forms an Et ester, yellow, m. 87.5-8.5°; this does not react with  $NH_3$  in  $H_2O$ , EtOH or when fused. II, with  $SOCl_2$  and  $NH_3$ , gives the amide, m. 280-80.8°. Reduction of II gives the 3- $NH_2$  deriv., m. 181-2°; Ac deriv., cream-colored, m. 254-5°. III forms an Et ester, m. 111.5-2°; amide, cream-colored, m. 216.5°. Mercuration of 4-nitro-1-naphthoic anhydride gives mainly anhydro-4-nitro-8-hydroxymercuri-1-naphthoic acid and a little of the 5- $NO_2$  compd.; heating this mixt. with concd. HCl gives 70% of 4,1- $C_{10}H_6(NO_2)CO_2H$ , whose Et ester m. 57-8° and Me ester m. 107.5-8.5°. The mother liquor gives 4% of the 5- $NO_2$  deriv.

C. J. WEST

**Some observations with triquinoyl.** F. BERGEL, *Ber.* 62B, 490-1(1929).—All attempts hitherto to prep. polymers of CO have been more or less failures. It may be assumed that triquinoyl,  $C_6O_8 \cdot 8H_2O$  (I), contains a preformed hexamer but the 8 mols. of  $H_2O$  somewhat alter the simple structure. In connection with the prepn. of I it was noted that the snow-white I *in vacuo* over  $P_2O_5$  slowly assumes a yellow color which again disappears in the air. When heated in a high vacuum over  $P_2O_5$  at the temp. of boiling alc. until its loss in wt. corresponds to almost exactly 8 mols.  $H_2O$  it assumes, without any apparent change in cryst. form, a deep brown-yellow color and, unlike prepn. which have lost only 1-2 mols.  $H_2O$ , it now deliquesces very rapidly in the air; it readily dissolves in  $H_2O$ , MeOH, EtOH,  $Me_2CO$  and  $Et_2O$  with reddish color and decomp. 136-7°. As combustion analyses indicated the presence of some  $H_2O$  and the substance cannot be converted back into I by  $H_2O$  or by cautious addn. of  $H_2O$  to an alc. or  $Me_2CO$  soln. it is probable that the dehydration of I is accompanied by an at least partial decompn. into rhodizonic or croconic acid; with  $BaCl_2$  the brown dehydration product gives, like I,  $CO_2$  and a red Ba salt,  $C_6O_8Ba \cdot BaCl_2 \cdot 4H_2O$ , and it must therefore still have the same skeleton as I. Dialysis gave no indications of the formation of higher polymerization products. Attempts to decomp. the substance at 135° apparently led to disproportionation;  $CO_2$ , C and a small quantity of a  $H_2O$ - and alc.-sol. substance were formed.

C. A. R.

**Polyiodoanthraquinones.** ALFRED ECKERT AND MAX KLINGER, *J. prakt. Chem.* [2], 121, 281-8(1929).—Tetraiodobenzoic acid (I) is best recrystd. from  $PhCl$ ; when 1 g. I is heated rapidly with 10 parts concd.  $H_2SO_4$  to 190-200° and kept at this temp. for 1 hr. until I is no longer evolved, cooled, dild. with  $H_2O$ , filtered, washed with hot  $H_2O$  until all of the red material has been extd., the insol. residue extd. with warm dil. NaOH until all of the violet color has been extd., the residue, recrystd. from  $PhCH_2OBz$ , gave 0.2 g. of a tetraiodoanthraquinone, yellow, m. 476° (decompn.); the high temp. of the reaction casts doubt as to its being the 1,2,3,4-tetra-I deriv. When a finely powd. mixt. of 1 g. I and 5 g.  $AlCl_3$  is heated to 150°

and then to 175°, I and HCl are evolved; the reaction product after extn. with HCl and then Na<sub>2</sub>CO<sub>3</sub> gave 0.03 g. of a *diiodoanthraquinone*, yellow, m. 290–2°. When 5 g. dry C<sub>14</sub>H<sub>2</sub>O<sub>2</sub> in 50 cc. oleum (70% SO<sub>3</sub>) is treated with 20 g. I in small portions and then heated under reflux for 8 hrs. at 180°, cooled, poured on ice, the product extd. with hot glacial AcOH, the AcOH removed from the ext. by distn., the product pptd. with H<sub>2</sub>O, washed with Na<sub>2</sub>CO<sub>3</sub>, then with NaOH and recrystd. from PhCl, yellow needles, m. 277° of a *triiodoanthraquinone* of unknown configuration are obtained. The residue from the AcOH extn. above was partly dissolved in PhNO<sub>2</sub>, filtered and on cooling gave brown needles of a *pentaiodoanthraquinone*, m. 368°. The residue from the AcOH and PhNO<sub>2</sub> extns. was recrystd. from PhNO<sub>2</sub> or PhCH<sub>2</sub>OH and gave yellow needles, m. above 500°, which is probably the *1,4,5,8-tetraiodoanthraquinone*. Attempts to replace the halogen with other groups (PhNH, MeO, etc.) were not successful. Other polyiodoanthraquinones are formed in the reaction but the quantities present were not sufficient for identification.

N. A. LANGE

**Reduction products of 1,1'-dianthraquinonyl.** ALFRED ECKERT. *J. prakt. Chem.* [2], 121, 273–7(1929).—Attempts to reduce 1,1'-dianthraquinonyl (I) to the corresponding dianthraquinonyl hydrocarbon were not successful (cf. C. A. 4, 2797) but gave *meso*-benzbianthrone (II) or reduction products which could not be identified. Yellow leaflets of *tetraacetyldianthrahydroquinone*, [C<sub>14</sub>H<sub>7</sub>(OAc)<sub>2</sub>]<sub>2</sub>, are obtained (cf. C. A. 4, 2799) when 2 g. I (recrystd. from PhNO<sub>2</sub>) is suspended in 30 cc. Ac<sub>2</sub>O, heated to boiling, treated with 6 g. Zn dust (in 1 g. portions during 2 hrs.) (cf. Liebermann, *Ber.* 21, 435(1888)), refluxed 2 hrs. longer, dild. with glacial AcOH, filtered hot, the ppt. of Zn extd. with hot AcOH until the filtrate is colorless, the combined filtrates evapd. to a small vol. until crystals sep., Zn(OAc)<sub>2</sub> removed from the crystals with dil. HCl and the product recrystd. from glacial AcOH with charcoal or from xylene, the green soln. in H<sub>2</sub>SO<sub>4</sub> on diln. with H<sub>2</sub>O gives helianthrone; a soln. in glacial AcOH after exposure to direct sunlight for a week gradually deposits II. The dehydration of dianthrahydroquinone to form II is explained by the desmotropic form (cf. C. A. 5, 1408) as follows:

N. A. LANGE

**Synthesis of trihydroxymethylantraquinones.** I. S. KEIMATSU AND I. HIRANO. *J. Pharm. Soc. Japan* 49, 147–56(1929).—The total no. of natural and synthetic trihydroxymethylantraquinones is 17, but the constitution of only 9 of these is known. In order to establish the constitution of some of the remaining compds., a few trihydroxymethylantraquinones were prepd. and their properties were compared with those given in the literature. For this purpose, 3 different dichlorophthalic anhydrides were condensed with *o*-ClC<sub>6</sub>H<sub>4</sub>Me (I) by Friedel-Craft's reaction and the resulting compds. were converted into the corresponding anthraquinones. Condensation of 3,6-Cl<sub>2</sub>C<sub>6</sub>H<sub>3</sub>(CO)<sub>2</sub>O and I gave 4',3,6-trichloro-3'-methyl-2-benzoylbenzoic acid, m. 157–8°, and that of 4,5-Cl<sub>2</sub>C<sub>6</sub>H<sub>3</sub>(CO)<sub>2</sub>O and I gave 4',4,5-trichloro-3'-methyl-2-benzoylbenzoic acid, m. 174–5°, while 3,4-Cl<sub>2</sub>C<sub>6</sub>H<sub>3</sub>(CO)<sub>2</sub>O and I gave 4',3,4-trichloro-3'-methyl-2-benzoylbenzoic acid or its isomeric 4',5,6-tri-Cl deriv., m. 265–6°. Heating of these benzoylbenzoic acids with fuming H<sub>2</sub>SO<sub>4</sub> gave 3,5,8-trichloro-2-methyl-9,10-anthraquinone, m. 250–1°, the 3,6,7-tri-Cl isomer, m. 314–5°, and the 3,5,6 (or 3,7,8)-tri-Cl compd., m. 264–5°, resp. (yield 67.7–90.2%). These anthraquinones and MeONa gave 87% of the corresponding tri-MeO derivs., m. 218–9°, 205–6° and 193–4°. These anthraquinones with HBr in glacial AcOH gave the corresponding tri-OH derivs., m. 211–2° (III) (tri-Ac deriv., m. 173–4°), m. 322–3° (IV), and m. 165–6° (V or VI), (tri-Ac deriv., m. 168–9°). III and HI gave 3,5,8-trihydroxy-2-methylanthrone, decomps. 238–9°. V or VI and HI gave 3,5,6(or 3,7,8)-trihydroxy-2-methylanthrone, decomps. 223–4°. A comparison of the chem. and phys. properties of these compds. with those given in the literature showed that IV is a new compd. and V or VI corresponds to Hesse's chrysarone (C. A. 2, 2282) while III corresponds to H.'s rhabarberone (*Ann.* 309, 42) or Tschirch and Eijke's isoemodin (*Schweiz. Wochschr. Pharm.* 1904, Nos. 40 and 41).

NAO UYEH

**Reaction of alizarin and mercuric acetate.** FRANK C. WHITMORE AND G. J. LEUCK. *J. Am. Chem. Soc.* 51, 1951–2(1929).—Alizarin and excess of Hg(OAc)<sub>2</sub> give large

amts. of  $\text{HgOAc}$  and a product which appeared to be *acetoxymercuridihydroxyalizarin*,  $\text{C}_{16}\text{H}_{10}\text{O}_8\text{Hg}$ .  $\text{HCl}$  gives a yellow-red dye with properties similar to those of alizarin.  $\text{NaOH}$  corresponding to 4 HO groups gives a bluish red soln., changed on warming to red; this may be 1,2,5,8-tetrahydroxy-4-acetoxymercurianthraquinone. C. J. W.

**9-Benzohydrylanthrone and isodianthranyl.** EDWARD DE BARRY BARNETT AND NORMAN F. GOODWAY. *J. Chem. Soc.* 1929, 813-4.—Anthrone (8 g.) and 20 cc. of  $\text{Ph}_2\text{CHCl}$  in 100 cc. of 25%  $\text{KOH}$  were boiled for 20 mins. to a pale soln. The 9-benzohydrylanthrone (I), m. 188-9°, was cooled, washed with  $\text{H}_2\text{O}$ , triturated with  $\text{Et}_2\text{O}$  and crystd. from  $\text{HOAc}$  and  $\text{PhH}$ -ligroin. With  $\text{C}_6\text{H}_5\text{N}$  and  $\text{Ac}_2\text{O}$ , it gave the *acetate*, m. 234-5°, which fails to check the m. 228-9° reported by Padova (*C. A.* 3, 2678). Ten g. of I and 20 g. of Zn dust were boiled in 100 cc. of  $\text{HOAc}$  while 20 cc. of concd.  $\text{HCl}$  was added (45 mins.); after boiling for 1 hr. more, the soln. was filtered hot and upon cooling, *isodianthranyl*, m. 312° (after recrystn. from  $\text{HOAc}$  contg.  $\text{HCl}$  and twice from  $\text{PhH}$ ), crystd. The  $\text{HOAc}$  soln. contained  $\text{Ph}_2\text{CH}_2$ . A. S. CARTER

**Reactions between phenanthrenequinone and magnesylypyrroles.** QUINTINO MINGOIA. *Gazz. chim. ital.* 58, 673-9(1928).—Continuing earlier work (cf. *C. A.* 22, 242) on the behavior of quinones with magnesylypyrrole (I) and magnesylyndoles, further expts. show that phenanthrenequinone (II) reacts in a similar way to anthraquinone. I (prepd. by the method of Oddo, *C. A.* 4, 2460, from 1.2 g.  $\text{Mg}$ , 5.5 g.  $\text{EtBr}$  and 3.4 g. pyrrole, with elimination of all  $\text{C}_2\text{H}_5$ ) in  $\text{Et}_2\text{O}$  refluxed with II (5.2 g.) for 20 hrs., cooled, ice added, neutralized with dil.  $\text{H}_2\text{SO}_4$ , the 2 layers sepd., the aq. layer extd. with  $\text{Et}_2\text{O}$ , the combined  $\text{Et}_2\text{O}$  exts. evapd., the residue steam-distd., to remove pyrrole, the new residue dissolved in  $\text{AcOEt}$ , pptd. by petr. ether, dissolved in  $\text{C}_6\text{H}_6$  and pptd. again by petr. ether, yields 9,10-dipyrroledihydrophenanthrene,  $\text{C}_{22}\text{H}_{14}\text{N}_2$  (III), dark green, m. 190°, the constitution of which was verified by several tests. In the reaction between I and II, it is best to place II in a receptacle above the I in  $\text{Et}_2\text{O}$  so that the cloud of  $\text{Et}_2\text{O}$  will slowly dissolve the II and carry it to the I soln. below. Following the same technic, II (2.6 g.) heated with magnesylymethylketole (from 1.2 g.  $\text{Mg}$ , 5.5 g.  $\text{EtBr}$  and 6.5 g.  $\alpha$ -methylindole) for 24 hrs. on a water bath, cooled, decompd. with ice, the aq. layer neutralized with dil.  $\text{H}_2\text{SO}_4$ , the aq. layer then extd. with  $\text{Et}_2\text{O}$ , the combined  $\text{Et}_2\text{O}$  exts. evapd., the residue steam distd., the new residue dissolved in  $\text{AcOH}$ , pptd. with petr. ether, dissolved in benzine and pptd. with  $\text{C}_6\text{H}_6$ , yields 9,10-tetra- $\alpha$ -methylindylidihydrophenanthrene  $\text{C}_{30}\text{H}_{20}\text{N}_4$  (IV), dark violet, m. 154°, insol. in hot or cold aq. alk. carbonates and hydroxides, and in dil. mineral acids, gives a violet soln. in concd.  $\text{H}_2\text{SO}_4$ , in dil.  $\text{EtOH}$  ppts. with  $\text{AgNO}_3 + \text{NH}_4\text{OH}$  a gray *Ag deriv.*, sol. in excess  $\text{NH}_4\text{OH}$ . The formation of IV is thus analogous to the formation of rosindoles (cf. M., *C. A.* 21, 1117). IV, boiled 4 hrs. with excess  $\text{Ac}_2\text{O}$  with fused  $\text{AcONa}$ , the excess  $\text{Ac}_2\text{O}$  decompd. with water and the resinous product crystd. from dil  $\text{EtOH}$ , yields a *tetra-Ac deriv.*  $\text{C}_{30}\text{H}_{18}\text{N}_4\text{O}_4$ , m. 170°.

C. C. DAVIS

**1,2-Phenanthrenequinone.** LOUIS F. FIESER. *J. Am. Chem. Soc.* 51, 1896-1906 (1929).—Coupling of 2-phenanthrol with  $p\text{-HO}_2\text{SC}_6\text{H}_4\text{N}_2\text{X}$  and reduction of the dye gives nearly quant. 1-amino-2-phenanthrol (I), pale gray, darkens 210° but with no definite point of decompn.; *HCl salt*, decomp. about 250° and gives a cherry-red soln. with warm concd.  $\text{H}_2\text{SO}_4$ . I (1 g.) and 10 cc.  $\text{Ac}_2\text{O}$ , boiled until the mono-Ac deriv. has just dissolved, give the *diacetate*, m. 227° (cor.); boiling the crude acetylation product with  $\text{EtOH-HCl}$  gives 1-acetyl-amino-2-phenanthrol, m. 295°; longer boiling of the acetylation mixt. with  $\text{Ac}_2\text{O}$  and  $\text{AcONa}$  gives the *triacetate*, m. 125°; heating either the di- or triacetate until no more  $\text{AcOH}$  or  $\text{Ac}_2\text{O}$  is evolved gives the *oxazole*

deriv. nearly quant. 1,2-phenanthrenequinone (II), brilliant red, m. 244° (cor., ompn.); concd.  $\text{H}_2\text{SO}_4$  gives a brilliant blue color, quickly changing to an intense

sap-green. Reduction of II gives 1,2-dihydroxyphenanthrene, m. 178°; *di*-MeO deriv., m. 102°. II,  $\text{Ac}_2\text{O}$  and concd.  $\text{H}_2\text{SO}_4$ , with cooling, give 36% of 1,2,4-triacetoxypheanthrene, m. 189° (cor.); alk. hydrolysis in a N atm. gives 88% of 2-hydroxy-1,4-phenanthrenequinone (III), orange-yellow, m. 190° (cor., decompn.); the soln. in concd.  $\text{H}_2\text{SO}_4$  is green, in alkali, red. 2-MeO deriv., m. 172.5°. The Ag salt of III and allyl bromide in  $\text{C}_6\text{H}_6$  give a mixt. of 4-allyoxy-1,2-phenanthrenequinone, dark red, m. 128°, and the 3-allyl deriv. of III, orange, m. 157°; the alk. soln. of the latter is grape-purple but the color disappears completely on boiling. Cleavage of III by alkali gives 1-aceto-2-naphthylglyoxylic acid, m. 181° (decompn.); Me ether, m. 112°. II and  $\text{NaHSO}_3$  in dil. NaOH give 65% of Na 1,2-dihydroxyphenanthrene-4-sulfonate, gray powder; K salt, crystg. with 2  $\text{H}_2\text{O}$ ; *p*-toluidine salt, pale yellow, m. 248° (cor., decompn.); oxidation of the above Na salt with  $\text{CrO}_3$  and  $\text{H}_2\text{SO}_4$  gives Na 1,2-phenanthrenequinone-4-sulfonate, bright red, crystg. with 1  $\text{H}_2\text{O}$ ; *p*-toluidine salt, bright red, decomp. on heating. The remarkable stability of the  $\text{SO}_3\text{H}$  group of this quinone is probably due to the spatial arrangement of the mol.

C. J. WEST

Phenanthrenequinones related to alizarin and purpurin. LOUIS FREDERICK FISHER. *J. Am. Chem. Soc.* 51, 1935-42 (1929).—Reduction of 1,2-phenanthrenequinone with Zn and  $\text{AcONa}$  in  $\text{Ac}_2\text{O}$  gives 80% of 1,2-diacetoxypheanthrene, m. 146-7°; oxidation with  $\text{CrO}_3$  in  $\text{AcOH}$  gives 60% of 1,2-diacetoxypheanthrenequinone, orange, m. 257° (cor.) (decompn.), which is hydrolyzed to the 1,2-(*HO*)<sub>2</sub> deriv., very dark red, decomp. on heating; the alkali soln. and salt are green; the concd.  $\text{H}_2\text{SO}_4$  soln. is red and the  $\text{C}_6\text{H}_5\text{N}$  soln. crimson; it dyes unmordanted wood a pale bluish gray and wool or silk with Al or Cr mordant, dark green. 1,2,4-Triacetoxypheanthrenequinone, orange, m. 227-8° (decompn.); hydrolysis in a N atm. gives the 1,2,4-(*HO*)<sub>3</sub> deriv., which could not be recrystd. and decomp. on heating; the compd. from EtOH contains 1 mol. EtOH; the green alk. soln. is changed to a pale red by the air; the concd.  $\text{H}_2\text{SO}_4$  soln. is green, the  $\text{C}_6\text{H}_5\text{N}$  soln. cornflower-blue; it has scarcely any dyeing properties. Reductive acetylation of 3-hydroxy-1,4-phenanthrenequinone gives 1,3,4-triacetoxypheanthrene, m. 138°; oxidation with  $\text{CrO}_3$  in  $\text{AcOH}$  gives 47% of 1,3,4-triacetoxypheanthrenequinone, yellow, softens 220°, decomp. 240°; hydrolysis in a N atm. gives the 1,3,4-(*HO*)<sub>3</sub> deriv., very dark red; the green alk. soln. on exposure to the air becomes a pale pink; the concd.  $\text{H}_2\text{SO}_4$  soln. is deep red, the  $\text{C}_6\text{H}_5\text{N}$  soln. deep red, becoming green on diln. with  $\text{H}_2\text{O}$ ; it has poor dyeing properties. 4-Amino-3-phenanthrol diacetate, m. 211° (cor.); heating splits off  $\text{AcOH}$ , giving the oxazole of 4-amino-3-phenanthrol, pale yellow, m. 155° (86% yield). Oxidation with  $\text{CrO}_3$  in  $\text{AcOH}$  gives 47% of the oxazole of 4-amino-3-hydroxyphenanthrenequinone, orange, m. 282° (cor.), which could not be hydrolyzed by EtOH-NaOH. 4-Amino-3-hydroxyphenanthrenequinone triacetate, yellow, m. 207° (cor.); hydrolysis gives a *di*-Ac deriv., brown-yellow, decomp. 255-60°, slowly oxidized in the air; acid hydrolysis gives the oxazole.

C. J. WEST

Constitution of hydroxymethylanthraquinone. S. KEIMATSU AND I. HIRANO. *J. Pharm. Soc. Japan* 49, 140-7 (1929).—In spite of the work of Heller and Schulke (C. A. 3, 318) and of Ullmann and his co-workers (C. A. 8, 1584; 10, 2721), the positions of the Cl and Me groups in the chloromethylbenzoylbenzoic acid (I) and chloromethylanthraquinone (II) obtained by the condensation of *o*- $\text{C}_6\text{H}_4(\text{CO})_2\text{O}$  (III) and *o*- $\text{ClC}_6\text{H}_4\text{Me}$  (IV) and subsequent dehydration have not yet been satisfactorily detd. In order to solve this point, the following expts. were carried out. Twenty-five g. of III and 100 g. of IV were condensed by Friedel-Craft's reaction in presence of 50 g.  $\text{AlCl}_3$  to give 43 g. of I. Recrystn. of 13 g. of I from  $\text{C}_6\text{H}_6$  and  $\text{C}_6\text{H}_5\text{Me}$  several times gave 2 fractions, one difficultly sol. fraction (V) m. 182-3° (yield 9 g.), and the other, easily sol. fraction (VI), m. 176-7° (yield 3 g.). Fuming  $\text{H}_2\text{SO}_4$  with V gave Ullmann's 2-methyl-3-chloroanthraquinone (VII), m. 219°, whereas VI and fuming  $\text{H}_2\text{SO}_4$  gave 1-chloro-2-methylanthraquinone (VIII), m. 171°, showing that V should have the structure of 3'-methyl-4'-chloro-2-benzoylbenzoic acid, and VI, that of 2'-chloro-3'-methylbenzoylbenzoic acid. In other words, the Cl atom in V is located *para* to the CO group, while in VI it is *ortho* to the same group. In order to replace Cl with the OH group, Strouder and Adam's method (C. A. 21, 3053) was used. VII and MeONa gave 2-methyl-3-methoxyanthraquinone (VIII), m. 179-80°. Heating of VIII and HBr in glacial  $\text{AcOH}$  gave 2-methyl-3-hydroxyanthraquinone, m. 298-9°. Ac deriv., m. 284-5°. VIII and MeONa gave 1-methoxy-2-methylanthraquinone (IX), m. 156-7°. IX and HBr in glacial  $\text{AcOH}$  gave 1-hydroxy-2-methylanthraquinone, m. 184-5°. Ac deriv., m. 177-8°. The above facts show that in the condensation of III and IV, 2 chloromethylbenzoylbenzoic acids are produced, one having the Cl *para*, and the other *ortho* to the CO group, and on dehydration they give rise to 2 kinds of anthraquinones.

NAO UYER

**Retene and some of its derivatives.** LI MAN CHEUNG. *Bull. inst. pin* 1929, 108-10.—The origin and properties of retene are briefly reviewed. Below 160° rosin combines with S to give a reddish resin with sulfurous odor, the amt. of S entering into combination depending on the temp., time of heating and proportion of S used; above 160° the rosin-S combination is decompd. with evolution of H<sub>2</sub>S and MeSH; at 240-50° the CO<sub>2</sub>H of the rosin is split off, and the action of S can be represented by the equation  $C_{10}H_{14}O_2 + 5S = C_{14}H_{18} + 4H_2S + MeSH + CO_2$ . On the assumption that rosin oil consists of octahydrotetene, the action of S can be represented by the equation  $C_{18}H_{26} + 4S = C_{18}H_{18} + 4H_2S$ . By the following method 41% of the theoretical yield of retene was obtained from rosin oil: to 800 g. of light-colored rosin oil at 200° gradually add in small successive portions 370 g. S with stirring; toward the end of the reaction (about 5 hrs.) raise the temp. to 250°; when evolution of gas has ceased, add 160 g. of Fe filings and distil under partial vacuum (60-80 mm.), most of the yellowish distillate (which consists of a mixt. of rosin oil and crystd. retene) passing at 275-95°; ext. the distillate with hot 95% EtOH; the residue from the extn. (280 g. of viscous oil) is treated with 10% of its wt. of S, distd. and extd. with EtOH as above. The optimum proportion of S is 3-4 atoms per mol. of abietic acid in the case of rosin or of octahydrotetene (in the case of rosin oil), S derivs. of retene and their decompn. products being obtained when the amt. of S taken corresponds to that calcd. from the equations given above. Stable S derivs. of retene are formed at the distn. temp., and the best results were given by Fe filings for decompg. them, the yield of retene obtained with S alone or with CaO as desulfurizing agent being much lower than with Fe filings. Attempts to ext. the retene from the reaction products without vacuum distn. were unsuccessful. The purified retene, m. 98-9°, was identified with the natural product because it does not lower the m. p. of the latter, the picrate m. 126-7° and on treating with CrO<sub>3</sub> in AcOH it gives a quinone, m. 196-7°. Nitration of retenequinone in AcOH and Ac<sub>2</sub>O gave golden yellow crystals of dinitroretenequinone, m. 229-30°. Condensation of retenequinone with *p*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>NHNH<sub>2</sub> gave maddered prismatic crystals of retenequinone *p*-nitrophenylhydrazone, m. 219°, very sparingly sol in AcOH and EtOH. Nitration of retene gave ill-defined, resinous nitro derivs.

A. PAPNEAU-COUTURE

**Thianthrene.** III. K. FRIES, H. KOCH AND H. STUKENBROCK. *Ann.* 468, 162-201 (1929); cf. *C. A.* 9, 785.—Reduction of 18 g. 4-nitroveratrole by 68 g. SnCl<sub>2</sub> in concd. HCl gives 80% of the 4-NH<sub>2</sub> deriv., m. 85°; *Ac deriv.* (I), m. 135°. I (19.5 g.) in 200 cc hot PhMe, treated with 11 g. P<sub>2</sub>S<sub>5</sub> and 11 g. K<sub>2</sub>S and boiled 1 hr., gives 55% of 4,5-dimethoxythioacetanilide, yellow, m. 114°, which gives with K<sub>3</sub>Fe(CN)<sub>6</sub> in 2 N NaOH 40% of 2-methyl-5,6-dimethoxy[4',5'-benzothiazole], m. 75°, b<sub>14</sub> 184°; heating with KOH and abs. EtOH 30 hrs. at 100° (sealed tube) gives the salt of 4,5-dimethoxy-2 aminophenyl mercaptan, which was not purified but treated with NaNO<sub>2</sub>, giving 35-40% of 5,6-dimethoxy[phenylenediazosulfide], m. 138°; this decomp. at 160-90°, splitting off N and giving 2,3,6,7-tetramethoxythianthrene (II), m. 176° (the yield is always small). Reduction of veratrolesulfonylchloride with Zn and HCl gives 70-80% of 4,5-dimethoxyphenyl mercaptan (III), b<sub>14</sub> 138°. H<sub>2</sub>O<sub>2</sub> and III in EtOH give di[4,5-dimethoxyphenyl] disulfide, yellow, m. 89°. Oxidation of III with concd. H<sub>2</sub>SO<sub>4</sub> gives 30% II. HNO<sub>3</sub> (d. 1.2) and II in AcOH give the monosulfonide (IV), m. 196°; concd. H<sub>2</sub>SO<sub>4</sub> gives a blue color, changing to green on heating. HNO<sub>3</sub> (d. 1.4) and II in AcOH give the disulfonide (V), m. 259°, sol. in concd. H<sub>2</sub>SO<sub>4</sub> with a blue color and reduced by HBr-AcOH in the presence of NaHSO<sub>3</sub> to II. The hot soln. of II in AcOH, dild. with H<sub>2</sub>O so that all the II remains in soln. and treated with Cl for 2 mins., gives the sulfone sulfonide (VI), m. 275°; concd. H<sub>2</sub>SO<sub>4</sub> gives a deep blue soln., soon changing to red; H<sub>2</sub>O ppts. a bright red ppt., from which CCl<sub>4</sub> exts. the monosulfone, m. 253°; reduction with NaHSO<sub>3</sub> in AcOH gives the tri-Me ether of the tetrahydroxythianthrene sulfone sulfonide, m. 270°. VI also results upon oxidation of II with H<sub>2</sub>O<sub>2</sub>, and by the oxidation of the monosulfone with concd. HNO<sub>3</sub>. Boiling II in AcOH with H<sub>2</sub>O<sub>2</sub> 1 hr. gives the disulfone (VII), m. 296°; this is not reduced by HBr in AcOH. Heating 4 g. VII with 20 g. KOH and 20 cc. abs. EtOH 3 hrs. gives 4,5-dimethoxy-2-ethoxyphenylsulfonic acid, sinters 75°, m. 118-20° (decompn.), which is reduced by HBr-AcOH to 3,4,3',4'-tetramethoxy-5,5'-diethoxy-1,1'-diphenyl disulfide, m. 84°. The following merquinoid dithionium salts of II were prepd.: Sulfate, blue needles, m. 230-2° (decompn.), from 1 part II and 50 vol.-parts concd. H<sub>2</sub>SO<sub>4</sub> on standing 3 weeks; the blue H<sub>2</sub>SO<sub>4</sub> or green HCCl<sub>2</sub>H soln. is stable on heating; reduction with SnCl<sub>4</sub> or HI gives II; hydrolysis by H<sub>2</sub>O is not complete in 2 days; hydrolysis by 50% AcOH gives a mixt. of II and sulfonide. Perchlorate, green, decomp. 245°; chloride, greenish blue, m. 164-6° (decompn.); perbromide, green, m. 220-2° (decompn.); this also results from IV or

V and HBr-AcOH. Heating II with HI and AcOH gives about 50% of 2,3,6,7-tetrahydroxythianthrene (VIII), m. 273°; the concd.  $\text{H}_2\text{SO}_4$  soln. is green, changing to blue; in the air VIII slowly turns blue; Ac deriv., m. 224°.  $\text{H}_2\text{O}_2$  and VIII in AcOH give the compd.  $\text{C}_{12}\text{H}_8\text{O}_8\text{S}_2$  (isomerized sulfoxide), deep blue, decomps. 200°; the soln. in concd.  $\text{H}_2\text{SO}_4$  is greenish blue, in alkalis a dirty gray; reduction with  $\text{SnCl}_2$  in AcOH gives VIII. Acetylation of this compd., or oxidation of the Ac deriv. of VIII with dil.  $\text{HNO}_3$  gives tetraacetoxythianthrene sulfoxide, m. 213°, sapond. to the deep blue compd. The monosulfone of VIII results from the tetra-Me deriv. and HI, carbonizes above 300°; tetra-Ac deriv., m. 203°. VII and HI give the disulfone, m. above 310°; tetra-Ac deriv., m. 245°. Br in AcOH gives the 1,4,5-tri-Br deriv., m. above 340°, while excess of Br gives the 1,4,5,8-tetra-Br deriv., pale rose, m. above 350°;  $\text{FeCl}_3$  gives a blue color; the tetra-Ac deriv. decomps. at 300°. The following meriquinoid dithionium salts of VIII were prepd.: Sulfate, blue, unchanged at 330°; concd. HCl and  $\text{HCO}_2\text{H}$  give deep blue solns., concd.  $\text{H}_2\text{SO}_4$  a greenish blue color;  $\text{HNO}_3$  in AcOH gives a deep red soln. which remains on diln. with  $\text{H}_2\text{O}$ ; hydrolysis with  $\text{H}_2\text{O}$  is incomplete after 2 weeks. Perchlorate, green, which explodes on heating; bromide, blue, m. 250° (decompn.), chloride, blue, decomps. 220°. II, moistened with AcOH, treated with  $\text{HNO}_3$  (d. 1.52) and heated until the soln. is dark red, gives 2,3,6,7-tetramethoxy-(?)-din'trodiphenylsulfone, pale green, m. 238°; this also results from VI or the monosulfone and  $\text{HNO}_3$  on standing 5 mins. 4-Bromo-5-nitroveratrole and  $\text{Na}_2\text{S}$  in boiling EtOH give 4,5,4',5'-tetramethoxy-2,2'-dinitrodiphenyl 1,1'-sulfide, yellow, m. 209° (60% yield); reduction with  $\text{SnCl}_2$  and HCl gives the 2,2'-di- $\text{NH}_2$  deriv., m. 110°. 4-Nitro-4'-methylidiphenyl sulfide-2-sulfonic acid (IX), light yellow, m. 123°; heating IX with HBr-AcOH a short time gives the compd.  $[\text{p-MeC}_6\text{H}_4\text{SC}_6\text{H}_4(\text{NO}_2)_2\text{S}]_n$ , yellow, m. 154° (60% yield); with concd.  $\text{H}_2\text{SO}_4$  IX gives 3-nitro-6-methylthianthrene, golden yellow, m. 157°; concd.  $\text{H}_2\text{SO}_4$  gives a deep red-violet soln. Reduction gives the 3- $\text{NH}_2$  deriv., m. 130°, sol. in concd.  $\text{H}_2\text{SO}_4$  with a red-violet color (Ac deriv., m. 180°, sol. in concd.  $\text{H}_2\text{SO}_4$  with a dark violet color; allowed to stand in concd.  $\text{H}_2\text{SO}_4$  48 hrs., there results the 2-sulfonic acid, carbonizes above 270° (Ba salt)). The Ac deriv. and concd.  $\text{H}_2\text{SO}_4$  give the half quinoid sulfate, blue. 3-Nitro-6-aminothianthrene, dark red, m. 198°; Ac deriv., yellow, m. 205°; 3,6-Diaminothianthrene, m. 192°;  $\text{FeCl}_3$  gives the blue compd.,  $\text{C}_{12}\text{H}_{10}\text{N}_2\text{S}_2\text{Cl}$ .  $\text{FeCl}_3$ . 4-Nitro-3',4'-dimethoxydiphenyl sulfide-6-sulfonic acid, yellow, m. 131°. HBr-AcOH gives the compd.  $\text{C}_{20}\text{H}_{24}\text{O}_8\text{N}_2\text{S}_4$ , red, m. 196°. Concd.  $\text{H}_2\text{SO}_4$  gives 3-nitro-6,7-dimethoxythianthrene, yellow-red, m. 194°; 3- $\text{NH}_2$  deriv., m. 149° (Ac deriv., m. 180°). 2,2'-Diamino-4,4'-dinitrodiphenyl sulfide, red, m. 211°; di-Ac deriv., light yellow, m. 245°. 4-Nitro-2-aminophenyl mercaptan, orange-yellow, m. 108°; 2,2'-diamino-4,4'-dinitrodiphenyl disulfide, citron-yellow, m. 178°; di-Ac deriv., m. 263°; di-Bz deriv., citron-yellow, m. 225°. 2-Phenyl-5-nitrobenzothiazole, pale yellow, m. 193°.

C. J. WEST

**Thionaphthene.** K. FRIES AND E. HEMMECKE. *Ann.* 470, 1-19 (1929).—Nitration of 20 g. thionaphthene in 25 cc. AcOH at 50° with 10 cc.  $\text{HNO}_3$  (d. 1.52), heating at 110° for about 20 mins. gives 13 g. of the 3- $\text{NO}_2$  deriv. (I), yellow, m. 81°, volatile with steam and distd. undecompd. Reduction of I with  $\text{SnCl}_2$ -HCl gives the 3- $\text{NH}_2$  deriv. (Ac deriv., m. 168°); heating the  $\text{SnCl}_4$  salt in  $\text{H}_2\text{O}$  or heating the amine with dil. HCl gives the 3-HO deriv.; distn. of the amine *in vacuo* gives the sec. amine,  $\text{NH}_2$  being split off. The  $\text{SnCl}_4$  salt (10 g.), stirred with 50 cc. 40% NaOH, gives *di*[3-thionaphthene]amine, m. 117°; strong acids give intensely yellow salts, easily hydrolyzed. Reduction of I with  $\text{Na}_2\text{S}_2$  in 2 N NaOH gives the *di*-Na salt (II) of *aci*-IV, needles with 6  $\text{H}_2\text{O}$ ; heating II with concd. HCl gives a deep blue compd., which could not be purified; II did not react normally with  $\text{AcCl}$ ,  $\text{BzCl}$  and  $\text{Me}_2\text{SO}_4$ ; oxidation of II gives I (Br or  $\text{K}_3\text{Fe}(\text{CN})_6$ ); with  $\text{SnCl}_2$ -AcOH there results 3,3'-diamino-2,2'-dithionaphthene, yellow, m. 238° (decompn.); concd.  $\text{H}_2\text{SO}_4$  gives a violet color, slowly changing to blue; boiling AcOH gives a red color; Ac deriv. (III), m. 346° (decompn.), oxidation with  $\text{K}_3\text{Fe}(\text{CN})_6$  gives thioindigo-3,3'-diimine, orange-red, m. 228° (decompn.), which gives a green color in concd.  $\text{H}_2\text{SO}_4$ ; HCl salt, violet; the product could not be acetylated but the Ac deriv., bright red, m. 285°, results by the oxidation of III. The aq. soln. of II and dil. AcOH give 3,3'-dinitro[2,2'-dithionaphthene] 2,3,2',3'-tetrahydride (IV), m. 126°. AcOH gives a mixt. of *d*[2,2'-thionaphthe deriv., corresponding to IV, m. 150° (HCl salt, decomps. 300°), and 3-amino[*di*2,2'-thionaphthene] 2,3-dihydride gives V with  $\text{NaNO}_2$  and  $\text{H}_2\text{SO}_4$ ; and 3-amino[*di*2,2'-thionaphthene] 2,3-dihydride m. 83.5° (HCl salt, needles; Ac deriv., m. 231°), gives V with  $\text{NaNO}_2$ . These are sep'd. by extg. the bases with AcOH and crystg. from hot  $\text{C}_6\text{H}_6$ . Nitration of thionaphthene at 0-8° with concd.  $\text{HNO}_3$  or dil.  $\text{HNO}_3$  (1:1) gives 3-nitro-2,3-dihydro-

[*di-2,3'-thionaphthenyl*] (VI), m. 161° (decompn.); the AcOH mother liquor, heated to 110°, gives I. Reduction of VI gives a mixt. of the 3-NH<sub>2</sub> deriv., m. 271° (decompn.); (HCl salt, decomps. 298°; Ac deriv., m. 225°), and *di-2,3'-thionaphthenyl*, m. 76°. also formed from the amine and HNO<sub>3</sub>. C. J. West

**New syntheses of nitrogenated heterocyclic nuclei. II. 1,3,5-Triarylpyrazole-4-carboxylic and 1,3,5-triarylpyrazolic acids from aldehydrazones and benzoylacetate esters.** GAETANO MINUNNI AND SALVATORE D'URSO (WITH GIUSEPPE TROIA, ANTONINA CARNEVALE, GIOVANNI AREZZI AND CARMELO VIZZINI). *Gazz. chim. ital.* **58**, 691-712(1928).—In continuation of previous expts. (cf. M., Lazzarini and d'Urso, C. A. **20**, 599), 4 aromatic aldehyde phenylhydrazones were made to react with BzCH<sub>2</sub>-CO<sub>2</sub>Et (I) to extend the field of application of the new synthesis. The results show that, as with AcCH<sub>2</sub>-CO<sub>2</sub>Et, I leads to Et esters of trisubstituted pyrazolecarboxylic acids. As before, the position of the substituents in the pyrazole nucleus was established with certainty. I (7 g.), PhCH:NNHPh (5 g.) and ZnCl<sub>2</sub> (0.1 g.) heated 3 hrs. at 130-5° (stirring periodically with a Cu wire), an equal vol. of EtOH added, let stand several days in darkness (covering the crystd. mass with EtOH), filtered, washed with EtOH and purified with boiling EtOH and animal charcoal, yields 50% of Et 1,3,5-triphenylpyrazole-4-carboxylate (II), m. 145-6.5°. II (5 g.) heated with concd. H<sub>2</sub>SO<sub>4</sub> (25 g.) on a water bath until a drop in water no longer gives a ppt. sol. in KOH, cooled, poured slowly in a large excess of water, let stand several hrs., filtered, washed with water, dissolved in 10% KOH, filtered, dil. HCl added to the filtrate, filtered, washed, the residue purified with boiling EtOH and animal charcoal, yields the free acid (III) of II (cf. *J. prakt. Chem.* **58**, 152(1898)). II (5 g.) refluxed 0.5 hr. with KOH (5 g.) in EtOH (50 cc.), cooled rapidly, poured into a large vol. of water, filtered, dil. HCl (1:5) added to the filtrate, let stand several hrs., filtered, washed with water and then EtOH, boiled with a little EtOH, filtered (which removes a small quantity of a secondary product, m. 180-97°), purified with animal charcoal and recrystd. from boiling EtOH, yields III. If II is boiled for 3 hrs. with alc. KOH, there is obtained, besides III, a secondary product, m. around 165°. III heated on a sand bath until CO<sub>2</sub> is no longer evolved from the fused compd., cooled, dissolved in boiling EtOH, cooled, the ppt. dissolved in much hot EtOH, refluxed for 2 hrs. with animal charcoal, filtered, concd., the treatment repeated and the product recrystd. from boiling EtOH, yields 1,3,5-triphenylpyrazole, m. 140-40.5° (cf. *Ber.* **21**, 1206(1888); *Compt. rend.* **136**, 1264(1903)), contains no EtOH of crystn. as reported by Knorr and Laubmann (*loc. cit.*). These reactions establish the constitution of II. I (7 g.), *o*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>-CH:NNHPh (5 g.) and ZnCl<sub>2</sub> (0.06 g.), treated as in the prepn. of II, yield 80% of Et 1,5-diphenyl-3-*o*-nitrophenylpyrazole-4-carboxylate (IV), m. 115.5-17.5°. Treated in a similar way as II with concd. H<sub>2</sub>SO<sub>4</sub> or with alc. KOH, IV yields the free acid (V) C<sub>20</sub>H<sub>15</sub>O<sub>4</sub>N<sub>3</sub>. EtOH, m. 232.5-3.5°, loses its EtOH at 150°. The better yield is obtained with alc. KOH. Its purification is very laborious. V (2 g.) refluxed 5 mins. at 300°, dissolved in boiling EtOH, filtered, allowed to evap., the ppt. treated with dil. Na<sub>2</sub>CO<sub>3</sub>, filtered, washed with water, the residue treated with dil. Na<sub>2</sub>CO<sub>3</sub> twice more, the residue washed with water, dried, dissolved in hot EtOH, boiled 3 hrs. with a decolorizing powder, filtered, concd., allowed to evap. further and the cryst. mass. purified from hot EtOH, yields 1,5-diphenyl-3-*o*-nitrophenylpyrazole, m. 116-7°. The reaction is particularly violent with I, *m*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>-CH:NNHPh (VI) and ZnCl<sub>2</sub>, with low yields and much resinification, the best conditions being to heat I (7 g.), VI (5 g.) and ZnCl<sub>2</sub> (0.06-0.7 g.) 3 hrs. at 135° and purifying with EtOH as before, which yields 45% of Et 1,5-diphenyl-3-*m*-nitrophenylpyrazole-4-carboxylate (VII), lustrous yellow, m. 126.5-27.5°. VII refluxed 0.5 hr. with 10% alc. KOH (10 parts), poured into water, filtered, the filtrate acidified with dil. HCl and the ppt. purified with animal charcoal and boiling EtOH, forms the free acid (VIII), m. 230° (decompn.). It can be prepd. in a purer state and in higher yield (50%) by heating VII (5 g.) and concd. H<sub>2</sub>SO<sub>4</sub> (25 g.) for 2 hrs. on a water bath, cooling, pouring on ice, letting stand several hrs., filtering, washing with water and then EtOH, dissolving in boiling EtOH (150 cc.), filtering, and animal charcoal, filtering and repeating the purification. It is then a straw color, contains 1 mol. of EtOH of crystn. and m. 232° (decompn.). VIII heated to 290°, cooled, dissolved in boiling EtOH (40 cc.), filtered, concd., allowed to evap. further, the residue treated repeatedly with hot 10% Na<sub>2</sub>CO<sub>3</sub> until the latter soln. no longer becomes turbid with HCl, the residue refluxed 3 hrs. with EtOH and animal charcoal, and finally purified again from EtOH, yields 60% of 1,5-diphenyl-3-*m*-nitrophenylpyrazole, yellowish, m. 137.5-9°. VII (5 g.) refluxed with 10% alc. KOH for 3 hrs., evapd. to dryness, the residue boiled with a little water, filtered, the residue digested

in dil. HCl (1:5), filtered, the residue refluxed with EtOH, then with  $C_6H_6$ , evapd., dissolved in a min. of boiling  $PhNO_2$ , filtered hot, let stand, the ppt. washed with boiling  $C_6H_6$  and dried *in vacuo*, yields 1.5 g. of the *azoxy deriv.* of VIII,  $C_{14}H_{10}O_3N_2$ , turns brown toward  $235^\circ$ , m.  $240-7^\circ$  (decompn.) to a brown liquid. Dil. alc.  $PhHNNH_2$  (50 g.) added slowly to dil. alc.  $p-O_2NC_6H_4CHO$  (68 g.), cooling if necessary to prevent undue violence and the product recrystd. from boiling EtOH, yields *p-nitrobenzaldehyde phenylhydrazone* (IX), dark red with metallic luster, m.  $153-4^\circ$ . As in the formation of VII, the reaction of I, IX and  $ZnCl_2$  is vigorous. The best yield is obtained by heating IX (2 g.), I (2 g.) and  $ZnCl_2$  (0.20 g.) for 30 mins. at  $125-30^\circ$ , purifying the product with EtOH as before and finally purifying by pptn. from EtOH with  $C_6H_6$ , which gives 50% of *Et 1,5-diphenyl-3-p-nitrophenylpyrazole-4-carboxylate* (X), m.  $166-7^\circ$ . From the EtOH- $C_6H_6$  mother liquor was isolated a very small quantity of a brown-red secondary compd., m.  $142-5^\circ$ , and the EtOH from the treatment of the crude X yields on concn. a small quantity of a brown-red compd., m.  $136-40^\circ$ . X (2 g.) heated with concd.  $H_2SO_4$  (10 g.) for 1.5 hrs. on a water bath, poured on ice, filtered, the residue boiled with EtOH and animal charcoal and finally recrystd. from EtOH, yields the *free acid* (XI), contains no EtOH of crystn., pale gray or mother-of-pearl color, m.  $248-90^\circ$  (decompn.). It is also formed when X is refluxed with 5% alc. KOH, in which case it m.  $248-9^\circ$ . XI heated at  $260^\circ$  until  $CO_2$  is no longer evolved, the product pulverized, dissolved in EtOH, filtered, the residue extd. with boiling EtOH, the ext. refluxed several hrs. with animal charcoal, filtered, concd., cooled and the ppt. recrystd. from EtOH, yields *1,5-diphenyl-3-p-nitrophenylpyrazole*, m.  $153-5^\circ$ . X boiled for 3 hrs with alc. KOH, evapd. to dryness, the residue extd. with hot water, filtered, washed with water, the residue recrystd. from hot water, digested in dil. HCl, filtered, washed with boiling water, dried, extd. with boiling EtOH, the residue dissolved in boiling  $PhNO_2$ , filtered, allowed to crystallize, filtered, washed with EtOH, again crystd. from  $PhNO_2$  and washed, yields the *azoxy deriv.* of XI, lustrous yellowish, m.  $285^\circ$ . The results of the new researches on the dehydro-condensation of aldehydrazones with  $\beta$ -ketonic acid esters confirm the belief already expressed in earlier work that the reactions represent a general method of synthesis not only of pyrazolecarboxylic acids, but also of alkyl and aryl derivs. of pyrazole.

C. C. DAVIS

**Synthesis of 4-(3,4-dihydroxyphenyl)thiazoles.** TREAT B. JOHNSON and ELIZABETH GATEWOOD. *J. Am. Chem. Soc.* 51, 1815-9(1929).— $AcNHCH_2CN$  (20 g) in 75 cc. abs. EtOH and 25 cc. concd.  $NH_4OH$ , cooled to  $10^\circ$  was satd. with  $H_2S$ , giving 19 g. *acetamidoacetothioamide*, m.  $123-4^\circ$ ; with 3,4-(HO) $_2C_6H_2COCH_2Cl$  (I) this gives *2-acetamidomethyl-4-[3,4-dihydroxyphenyl]thiazole-HCl*, crystg. with 1 EtOH, m.  $188-90^\circ$ ; digestion with concd. HCl gives *2-aminomethyl-4-[3,4-dihydroxyphenyl]thiazole di-HCl*, m.  $225-30^\circ$ . *Acetylmethylaminoacetothioamide*, m.  $156-7^\circ$ , in 16 g. yield by acetylating 20 g. of  $MeNHCH_2CN$ , dissolving in concd.  $NH_4OH$  and satg. with  $H_2S$ . The thioamide from  $Me_2(NH_2)CCN$ , m.  $185-6^\circ$ , with I gives *2- $\alpha$ -acetamidoisopropyl-4-[3,4-dihydroxyphenyl]thiazole*, crystg. with 2  $H_2O$ , m.  $198-200^\circ$ ; *HCl salt*, m.  $188-9^\circ$ . the *2-amino deriv.-HCl*, crystg. with 1  $H_2O$ , m.  $210-5^\circ$  (decompn.). The following 4-[3,4-dihydroxyphenyl]thiazoles were also prepd.: *2-acetylmethylaminomethyl-HCl*, m.  $186-8^\circ$ ; *2-methylaminomethyl*, crystg. with 1 EtOH, m.  $128-30^\circ$ ; *HCl salt*, m.  $220-5^\circ$ ; *2-mercapto*, crystg. with 1  $H_2O$ , m.  $250^\circ$ ; *2-phenyl*, m.  $164-5^\circ$ ; *2-amino-HCl*, crystg. with 1  $H_2O$ , m.  $230-5^\circ$ ; *2-methylamino-HCl*, m.  $275-80^\circ$ . These thiazoles are characterized by their stability in the air; all compds. thus far examd. are physiol active.

C. J. WEST

**Some derivatives of 4,5-naphtho-1,2-thiazole (naphth-1,2-thiazole).** R. STOLLÉ and W. BADSTÜBNER. *J. prakt. Chem.* [2], 121, 266-8(1929).—The ring system  $C_{10}H_8.CH:N.S$  is called 4,5-benzo-1,2-thiazole, and the corresponding  $C_{10}H_8$  derivs

are called 4,5-naphtho-1,2-thiazoles. The following compds. are described: *5,6-benzo-2,3-diketo-2,3-dihydrothionaphthene*, red, m.  $171^\circ$ ; [4,5-(2',3'-naphtho)-1,2-thiazole] *3-carboxamide*, (I), m.  $208^\circ$ ; *acid*, from I, yellow, m.  $197^\circ$  (decompn.); [4,5-(1',2'-naphtho)-1,2-thiazole] *3-carboxamide*, brown, m.  $225^\circ$ .

M. A. DAHLEN

**Stability of diazonium salts of the triazole series.** JOSEPH REILLY and DENIS MADDEN. *J. Chem. Soc.* 1929, 815-6.— $NH_2C(NH)NHNH_2$ ,  $HNO_3$  (I) (25 g.) was heated with 20 g. of  $EtCO_2H$  and a few cc. of  $H_2O$  for 24 hrs., followed by neutralization with  $K_2CO_3$  and evapn. to dryness. The residue was extd. with  $AcOEt$  and the soln. treated with concd.  $HNO_3$ , giving 17 g. of *5-amino-3-ethyl-1,2,4-triazole nitrate* (II), m.  $167^\circ$  (after recrystn. from hot  $EtOAc-EtOH$  mixt.); the *free triazole*, (II), gave the following compds. upon diazotization and coupling: *5-azo- $\beta$ -naphthylamine*, red, m.  $259^\circ$ ; *5-azo- $\beta$ -naphthol*, orange-red, m.  $180-1^\circ$ ; *5-azoacetylacetone*, yellow,

m. 236°; and 5-diazo-chloroaurate. The 3-isobutyltriazole (16 g.), m. 171°, corresponding to II, was prepd. in the same manner from 20 g. of isovaleric acid and 20 g. of I. The stability of triazolediazonium salts is increased by alkyl substitution, the effect increasing with the mol. wt. of the alkyl group. A. S. CARTER

**Constitution of carthamin.** II. CHIKA KURODA. *Proc. Imp. Acad.* (Tokyo) 5, 82-5 (1929); cf. C. A. 23, 1906.—Carthamin, heated with dil.  $H_3PO_4$ , gives a mixt. of carthamidin (I),  $C_{15}H_{12}O_8$ , pale yellow, crystg. with 1  $H_2O$ , m. 218°, unstable, and isocarthamidin (II), isomeric with I, yellow, crystg. with 1  $H_2O$ , m. 238°. Various color reactions are given for I and II. I and  $Ac_2O$  with  $H_2SO_4$  give the  $\alpha$ -Ac deriv. (III), m. 158°; Ac deriv. (IV) of II, m. 180°. I or III with  $AcONa$  and  $Ac_2O$  at 125° gives the  $\beta$ -Ac deriv. of I, m. 143°. II or IV with  $AcONa$  and  $Ac_2O$  at 140-50° gives the  $\gamma$ -Ac deriv. of I, m. 179°. II is probably 5,6,7,8-tetrahydroxyflavanone. III,  $\beta$ -Carthamidin methyl ether and its synthesis. *Ibid* 86.— $\beta$ -Acetylcarthamidin,  $Me_2SO_4$  and KOH in an atm. of H give the  $\beta$ -Me ether, m. 112°, identical with 2,3,4,6,4'-pentamethoxychalcone. C. J. WEST

**Dissociation into free radicals of substituted dixanthyls.** V. The rate of dissociation. JAMES B. CONANT and MILDRED W. EVANS. *J. Am. Chem. Soc.* 51, 1925-35 (1929); cf. C. A. 21, 3055.—The rate of O absorption of dibutyl dixanthyl in PhBr at 25° has been measured by means of a differential pressure app. The reaction is of the 1st order until about 0.5 mole of O per mole of dixanthyl deriv. has been absorbed. The rate is independent of the concn. of the O in the soln. It thus appears that the rate-controlling step is the dissocn. of the dixanthyl deriv. into a free radical. The rates of dissocn. of the following dixanthyl derivs. in PhBr have been measured at different temps. by following the rate of O absorption: di-Me, di-Et, di-Pr, di-Bu, di-Am, di-iso-Am. The energy of activation has been calcd. from the temp. coeff. of the reaction velocity. A parallelism has been found between the rates of dissocn. and the temp. at which appreciable dissocn. first occurs as evidenced by the appearance of color in a dil. soln. The results are given in tables and curves. C. J. WEST

**5,8-Dihydroxy- $\alpha$ -anthrapyridinequinones.** HARRY RAUDNITZ (WITH GRETE LAUBE). *Ber.* 62B, 509-13 (1929).—As might have been expected from the close relationship between phthalic and quinolinic acids, quinolinic anhydride (I) with  $C_6H_6$  and  $AlCl_3$  gives  $\beta$ -benzoylpicolinic acid which yields the N analog,  $\alpha$ -anthrapyridinequinone, of anthraquinone. This quinone, heated with NaOH and Zn dust, forms a deep blue soln decolorized by shaking with air, the presence of the pyridine ring in the anthraquinone complex apparently deepening the color as compared with anthraquinone. It seemed of interest, therefore, to prep. 5,8-dihydroxy- $\alpha$ -anthrapyridinequinone ( $\alpha$ -pyrquinizarin) (II) and 5,8-dihydro-6,7-benzo- $\alpha$ -anthrapyridinequinone (6,7-benzo- $\alpha$ -pyrquinizarin) (III), analogous to quinizarin (IV) and 1,4-dihydroxy-2,3-benzanthraquinone (V), resp., to det. the spectroscopic effect of the pyridine ring. This effect proved to be a distinct shifting of the max. of the absorption bands toward the red, as shown by the following values for these max. in KOH,  $H_2SO_4$ , and  $H_2SO_4$ - $H_3BO_3$ , resp.: IV, violet, 596.1, 553.7, 317.7; red, 548.3, 509.6, 476.4; red, 547.5, 508.8, 473.5. II, violet, 600.7, 561.5; crimson, 574, 532.2; pink, 547.5, 506.5, 473.5. V, violet, 584, 539, 505, orange, 540, 500, 469; yellow, 534, 496.5, 463. III, red-violet, 586.5, 544; yellow-red, 1-sided absorption beginning in the yellow; orange, 541.5, 503, 467. Whereas I with aromatic compds. and  $AlCl_3$  gives only ketopicolinic acids, with a  $Na-AlCl_4$  melt (1:5), it yields  $\alpha$ -anthrapyridinequinones directly with aromatic compds. contg. HO groups in the 1,4-positions, but, unlike  $C_6H_4(CO)_2O$ , it does not condense with  $o$ - $C_6H_3(OH)_2$ . IV, m. 198°, and V, dark red, m. 349°, were also obtained in very pure form from  $C_6H_4(CO)_2O$  and  $p$ - $C_6H_4(OH)_2$  and 1,4- $C_{10}H_6(OH)_2$ , resp., with  $Na-AlCl_4$ . II, dark red, sublimes *in vacuo*, m. 237°, isolated as the Na salt, dark blue-violet powder (yield, 44%). III, brown-red, sublimes *in vacuo* with partial decompn., m. 363°; Na salt, dark violet powder. C. A. REICHERT

**Substituted aromatic aldehydes in Hantzsch's pyridine condensation.** I. Methoxy-, chloro- and hydroxybenzaldehydes. LEONARD E. HINKEL and WM. R. MADEL. *J. Chem. Soc.* 1929, 750-4.—One mol. of  $p$ - $MeOC_6H_4CHO$ , 2 mols. of  $AcCH_2CO_2Et$  and 20 cc. of EtOH were satd. with  $NH_3$  and after standing 1 hr. were heated on a water bath for several hrs.; 65% of 2,6-dimethyl-3,5-dicarboethoxy-4- $p$ -methoxyphenyl-1,4-dihydropyridine (I), m. 159°, crystd. upon cooling. I was made into a paste with EtOH and  $N_2O_5$  passed in until a clear soln. resulted. The EtOH was removed by evapn., the residue was neutralized with  $Na_2CO_3$  soln. and extd. with  $Et_2O$ . 2,6-Dimethyl-3,5-dicarboethoxy-4- $p$ -methoxyphenylpyridine (II) crystd. upon evapn. of the  $Et_2O$  and after recrystn. from ligroin, m. 50°. In the same manner as in the case of I, the following similarly substituted dihydropyridines were prepd.: 4- $o$ -methoxyphenyl

(48%), m. 151°; 4-*m*-methoxyphenyl (33%), m. 120°; 4-*p*-chlorophenyl (69%), m. 149°; 4-*o*-chlorophenyl (38%), m. 132° (from aq. MeOH); 4-*m*-chlorophenyl (78%), m. 142° (from aq. MeOH); 4-*p*-hydroxyphenyl (49%), m. 227° (from EtOH); and 4-*m*-hydroxyphenyl (36%), m. 202°. No product could be obtained in the case of the *o*-HO deriv. Following a course analogous to the prepn. of II, the corresponding analogs of II were made: *o*-MeO, m. 65°; *m*-MeO, m. 82°; *p*-Cl, m. 68°; *o*-Cl, m. 62°; *m*-Cl, m. 53°; the HO derivs. formed nitroso compds. and could not be oxidized. From the theory of alternate polarities of Lapworth and Shoesmith (*C. A.* 16, 3078) the negative substituents in the *o*- and *p*-positions should increase the activity of BzH and a similar group in the *m*-position should diminish it. This is not the case; comparing the yields, it is seen that they do not agree among themselves, for with the HO derivs. the *m*- is greater than the *o*-, and with the Cl-derivs., the *m*- is greater than either *o*- or *p*-. In all cases the activity of BzH (which gives 90% yields) is decreased by the substituents.

A. S. CARTER

Action of diazonium salts on 2,5-dimethyl-6-hydroxypyrazine. III. G. GASTALDI AND E. PRINCIVALLE. *Gazz. chim. ital.* 58, 679-82 (1928).—The expts. described show that 2,5-dimethyl-6-hydroxypyrazine (I) (*C. A.* 16, 101) reacts in a normal way with phenyl-, *p*- and *o*-tolyl diazonium salts, in the sense that the corresponding azo compds. have the constitution:  $\text{N}:\text{C}(\text{OH})\cdot\text{CMe}:\text{N}:\text{C}(\text{N}:\text{NR})\cdot\text{CMe}$ . They are stable, are

more acidic than the corresponding hydroxypyrazines and give stable cryst. salts. The ease with which I couples with the diazonium salts indicates that it reacts in the lactic form, and possibly with alkyl halides it first forms *O*-ethers which are then transformed into *N*-derivs. (*C. A.* 23, 602). Preliminary expts. indicate that the product of the coupling of I and *p*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>N<sub>2</sub>Cl is not an azo compd. Coupling of I and PhN<sub>2</sub>Cl was carried out in an alk. medium, the alk. salt being then filtered, dissolved in water, decompd. with HCl, dried in air and recrystd. from EtOH, which gives a good yield of 3-phenylazo-2,5-dimethyl-6-hydroxypyrazine (II), orange-red, m. 208° (decompn.). Na salt, C<sub>13</sub>H<sub>13</sub>ON<sub>4</sub>Na, orange-red, by heating II with excess aq. NaOH and allowing to cool slowly. Prepd. in the same way, I and *p*-MeC<sub>6</sub>H<sub>4</sub>N<sub>2</sub>Cl give almost quant. 3-*p*-tolylazo-2,5-dimethyl-6-hydroxypyrazine, orange-yellow, m. 242° (decompn.). Na salt, C<sub>13</sub>H<sub>13</sub>ON<sub>4</sub>Na, orange-yellow. Likewise I and *o*-MeC<sub>6</sub>H<sub>4</sub>N<sub>2</sub>Cl yield 3-*o*-tolylazo-2,5-dimethyl-6-hydroxypyrazine, orange-yellow, m. 221° (decompn.). Na salt, C<sub>13</sub>H<sub>13</sub>ON<sub>4</sub>Na, orange-yellow.

C. C. DAVIS

Action of *o*-phenylenediamines upon dihydroxytartaric acid. FREDERICK D. CHATTAWAY AND WILLIAM G. HUMPHREY. *J. Chem. Soc.* 1929, 645-51.—When Na dihydroxytartrate is heated with aq. *o*-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub>, 2 mols. of the diamine react with 1 mol. only of the salt, forming quinoxaline-2,3-dicarboxy-*o*-phenylenediamide (I); Na dihydroxytartrate is only very sparingly sol. in H<sub>2</sub>O, and any excess above 1 mol. remains in suspension unchanged. When the filtered alk. soln. is partly neutralized with HCl, I seps. as a colorless cryst. powder, stable in neutral soln. and dissolving readily in cold dil. aq. alkali, from which it is reprecip. on addn. of a deficiency of acid. It dissolves in hot dil. HCl (1:50), but on cooling, the *o*-phenylenediamine salt (II) of quinoxaline-2,3-dicarboxylic acid (III) seps.; whereas, if it is dissolved in hot moderately concd. HCl (1:1), III seps. on cooling, *o*-phenylenediamine-HCl remaining in soln. The II and III may consequently be obtained directly from the original yellow condensation soln., the former by making the soln. weakly acid with HCl, and the latter by satg. it with gaseous HCl.

Attempts to acetylate or benzoylate I by the usual methods also cause decompn., with formation of the di-Ac or the di-Bz deriv. of *o*-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub>. Heated with Ac<sub>2</sub>O, III yields the anhydride, while dry NH<sub>3</sub> on this anhydride in C<sub>6</sub>H<sub>6</sub> suspension gives the NH<sub>4</sub> salt of 3-carbamylquinoxaline-2-carboxylic acid (IV), from which the acid itself may be obtained on acidification. This amic acid is converted into the corresponding imide (V) on being heated above its m. p., and into the Ac deriv. of the imide on boiling with Ac<sub>2</sub>O. On being heated above its m. p., III decompn., evolving CO<sub>2</sub> and yielding a small quantity (10%) of quinoxaline; better yields (30%) of this base are obtained by heating the NH<sub>4</sub> salt of the acid. In common with other N bases, quinoxaline forms a stable, well-crystd. monotetrachloroiodide. Similarly, Na chloro-quinoxaline-2,3-dicarboxy-*p*-chloro-*o*-phenylenediamide, from which the *p*-chloro-*o*-phenylenediamine salt of 6-chloroquinoxaline-2,3-dicarboxylic acid, and the free acid

(VI) are obtained by heating with dil. and with concd. HCl, resp. *p*-Bromo-*o*-phenylenediamine gives the corresponding Br deriv. These halogen-substituted derivs. are considerably less sol. than the unsubstituted compds., and are therefore more readily prepd. and purified; otherwise their reactions are analogous. The following compds. were prepd. and characterized: I, m. 184° (decompn.). II, lemon-yellow, m. 186° (decompn.). III, prisms contg. 2 mols. H<sub>2</sub>O of crystn., m. 190° (decompn. after loss of H<sub>2</sub>O at 110°); *Et* ester, C<sub>14</sub>H<sub>14</sub>O<sub>2</sub>N<sub>2</sub>, prisms, m. 83°; *NH*<sub>4</sub> salt, m. 220–30°; *anhydride*, pale yellow prisms decomp. and charring 250–60°. IV, m. 190–5° (decompn.). V, pale yellow, m. about 260° (decompn.); *Ac* deriv., leaflets, m. about 220° (decompn.). Quinoxaline mono-tetrachloroiodide, C<sub>8</sub>H<sub>2</sub>N<sub>2</sub>·HICl<sub>4</sub>, m. 125–30° (decompn.). 6-Chloroquinoxaline-2,3-dicarboxy-*p*-chloro-*o*-phenylenediamide, C<sub>18</sub>H<sub>6</sub>O<sub>2</sub>N<sub>4</sub>Cl<sub>2</sub>, m. 207° (decompn.). (*p*-chloro-*o*-phenylenediamine salt, C<sub>18</sub>H<sub>12</sub>O<sub>2</sub>N<sub>4</sub>Cl<sub>2</sub>, m. 205° (decompn.)); 6-bromoquinoxaline-2,3-dicarboxy-*p*-bromo-*o*-phenylenediamide, m. 198° (decompn.). (*p*-bromo-*o*-phenylenamine salt, m. 199° (decompn.)). VI, m. 175° (decompn.) (*anhydride*, m. 235–40° (decompn.)), *Et* *H* ester, m. 159°; *di-Et* ester, m. 60°; *NH*<sub>4</sub> salt, m. 215–25° (decompn.)). 6-Chloroquinoxaline, m. 60°. 6-Bromoquinoxaline-2,3-dicarboxylic acid, m. 172° (decompn.) (*anhydride*, m. 235–45° (decompn.)), *Et* *H* ester, m. 161°. *di-Et* ester, m. 69°. *NH*<sub>4</sub> salt, m. 235–40° (decompn.)). 6-Bromoquinoxaline, m. 56°. Pyrazine-tetracarboxylic acid (by oxidation of the anhydride of III), m. 205° (decompn.), *di-K* *di-II* salt is cryst., *tetra-Et* ester, m. 104°. W. O. E.

**Calycanthine. I.** The isolation of calycanthine from *Meratia praecox*. RICHARD H. F. MANSKE. *J. Am. Chem. Soc.* 51, 1836–9 (1929).—Calycanthine has been isolated from *Meratia praecox*, Rehd. and Wils., a shrub native to Asia, 4 kg. of seeds giving 70 g. alkaloid, identical with that from *Calycanthus floridus*, L. Two other alkaloids, m. 197–8°, and an oil, were isolated in small quantities, but have not been investigated. The existence of glucose, or a sugar which gives glucosazone, in the seeds has been shown. Xylose was isolated from the epicarp of the seeds by hydrolysis with dil. H<sub>2</sub>SO<sub>4</sub>. C. J. WAST

**Synthetical experiments on the aporphine alkaloids. V. Laurotetanine.** Syntheses of 2,3,6,7- and 3,4,6,7-tetramethoxyaporphines. ROBERT K. CALLOW, JOHN M. GULLAND AND ROBERT D. HAWORTH. *J. Chem. Soc.* 1929, 658–70.—Recent investigations have shown that isoglaucine (II), obtained by Gorter (*C. A.* 16, 2470) from laurotetanine (I) (R=OH, R'=MeO, the positions of which may be the reverse of that shown), is impure glaucine (III) and does not contain the vicinal homocatechol group in ring III. It occurred to the authors of this paper that this vicinal arrangement does not occur in the aporphine series and that a synthesis of 2,3,6,7-tetramethoxyaporphine (II) and 3,4,6,7-tetramethoxyaporphine (IV) would be of value in detg. the true nature of I. Synthesis of these compds. shows as expected that neither resembles isoglaucine. After some difficulty 6'-nitro-3',4'-dimethoxyphenylaceto-β-2,3-dimethoxyphenylethylamide (V), m. 144.5–5.5° (9.5 g.), was obtained by adding 6,3,4-O<sub>2</sub>N(MeO)<sub>2</sub>·C<sub>6</sub>H<sub>2</sub>CH<sub>2</sub>COCl, obtained from the corresponding acid (13.1 g.) and PCl<sub>5</sub> in CHCl<sub>3</sub>, to a mixt. of 2,3-(MeO)<sub>2</sub>C<sub>6</sub>H<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>NH<sub>2</sub> (12 g.) in CHCl<sub>3</sub> and dil. aq. NaOH. With PCl<sub>5</sub> in cold CHCl<sub>3</sub>, 19.5 g. of V was converted into 6 g. of 6'-nitro-3',4',5,6-tetramethoxy-1-benzyl-3,4-dihydroisoquinoline, m. 187.5–9.5°. The methiodide of this base, m. 146–8° (3.5 g.), was reduced by means of Zn dust and HCl to 2.2 g. of 6'-amino-3',4',5,6-tetramethoxy-1-benzyl-2-methyl-1,2,3,4-tetrahydroisoquinoline (VI), m. 233.5–5° (decompn.). A diazotized soln. of this compd. gave with an alk. β-naphthol a red ppt. of an azo dye. Diazotization of VI in MeOH-alc.-H<sub>2</sub>SO<sub>4</sub> gave *di*-2,3,6,7-tetramethoxyaporphine (II), pale yellow needles, m. 115.5–6.5° (0.55 g. from 1.94 g. of the di-HCl salt). A hydriodide, m. 227.5–30.5°, and a methiodide, m. 204–8°, were also obtained from II. Attempts to resolve II by means of *d*- and *l*-tartaric acids were unsuccessful. Colors with H<sub>2</sub>SO<sub>4</sub>, HNO<sub>3</sub>, Mandelin's, Fröhde's, and Erdman's reagents did not resemble those described by Gorter for isoglaucine. The yield of 6,3,4-O<sub>2</sub>N(MeO)<sub>2</sub>·C<sub>6</sub>H<sub>2</sub>CH<sub>2</sub>CO<sub>2</sub>H prepd. by the method of Oxford and Raper (*C. A.* 21, 1649) was increased from 60 to 77% by increasing the proportion of KOEt and (CO<sub>2</sub>Et)<sub>2</sub> to 6-nitrohomoveratrole. By the interaction of 2,3,4-O<sub>2</sub>N(MeO)<sub>2</sub>·C<sub>6</sub>H<sub>2</sub>CH<sub>2</sub>COCl from 19 g. of the corresponding acid (cf. Gulland and Haworth, *C. A.* 22, 2949) with 14 g. of β-2,3-dimethoxy-1-oxyphenylethylamine, 26 g. of 2'-nitro-3',4'-dimethoxyphenylaceto-β-2,3-dimethoxyphenylethylamide (VII), m. 95–6° was obtained. With PCl<sub>5</sub> in CHCl<sub>3</sub>, 4.5 g. VII gave 2.5 g. 2'-nitro-3',4',5,6-tetramethoxy-1-benzyl-3,4-dihydroisoquinoline (VIII), peach-colored prisms, m. 152–6°. The methiodide, m. 183–4° (decompn.); 6 g., reduced by Zn and HCl, gave 3.7 g. of 2'-amino-3',4',5,6-tetramethoxy-1-benzyl-2-methyltetrahydroisoquinoline (IX), m. 117.5–9.5°. A diazotized soln. of this amine in HCl gave with alk. β-naphthol scarlet azo dye. By diazotization of 3.72 g. IX in MeOH-alc.-H<sub>2</sub>SO<sub>4</sub>, 0.87 g. of

in dil. HCl (1:5), filtered, the residue refluxed with EtOH, then with  $C_6H_6$ , evapd., dissolved in a min. of boiling  $PhNO_2$ , filtered hot, let stand, the ppt. washed with boiling  $C_6H_6$  and dried *in vacuo*, yields 1.5 g. of the azoxy deriv. of VIII,  $C_{14}H_{10}O_2N_2$ , turns brown toward  $235^\circ$ , m.  $240-7^\circ$  (decompn.) to a brown liquid. Dil. alc.  $PhHNNH_2$  (50 g.) added slowly to dil. alc.  $p-O_2NC_6H_4CHO$  (68 g.), cooling if necessary to prevent undue violence and the product recrystd. from boiling EtOH, yields *p*-nitrobenzaldehyde phenylhydrazone (IX), dark red with metallic luster, m.  $153-4^\circ$ . As in the formation of VII, the reaction of I, IX and  $ZnCl_2$  is vigorous. The best yield is obtained by heating IX (2 g.), I (2 g.) and  $ZnCl_2$  (0.20 g.) for 30 mins. at  $125-30^\circ$ , purifying the product with EtOH as before and finally purifying by pptn. from EtOH with  $C_6H_6$ , which gives 50% of Et 1,5-diphenyl-3-*p*-nitrophenylpyrazole-4-carboxylate (X), m.  $166-7^\circ$ . From the EtOH- $C_6H_6$  mother liquor was isolated a very small quantity of a brown-red secondary compd., m.  $142-5^\circ$ , and the EtOH from the treatment of the crude X yields on concn. a small quantity of a brown-red compd., m.  $136-40^\circ$ . X (2 g.) heated with concd.  $H_2SO_4$  (10 g.) for 1.5 hrs. on a water bath, poured on ice, filtered, the residue boiled with EtOH and animal charcoal and finally recrystd. from EtOH, yields the free acid (XI), contains no EtOH of crystn., pale gray or mother-of-pearl color, m.  $248-50^\circ$  (decompn.). It is also formed when X is refluxed with 5% alc. KOH, in which case it m.  $248-9^\circ$ . XI heated at  $260^\circ$  until  $CO_2$  is no longer evolved, the product pulverized, dissolved in EtOH, filtered, the residue extd. with boiling EtOH, the ext. refluxed several hrs. with animal charcoal, filtered, concd., cooled and the ppt. recrystd. from EtOH, yields 1,5-diphenyl-3-*p*-nitrophenylpyrazole, m.  $153-5^\circ$ . X boiled for 3 hrs with alc. KOH, evapd. to dryness, the residue extd. with hot water, filtered, washed with water, the residue recrystd. from hot water, digested in dil. HCl, filtered, washed with boiling water, dried, extd. with boiling EtOH, the residue dissolved in boiling  $PhNO_2$ , filtered, allowed to crystallize, filtered, washed with EtOH, again crystd. from  $PhNO_2$  and washed, yields the azoxy deriv. of XI, lustrous yellowish, m.  $285^\circ$ . The results of the new researches on the dehydro-condensation of aldehydrazones with  $\beta$ -ketonic acid esters confirm the belief already expressed in earlier work that the reactions represent a general method of synthesis not only of pyrazolecarboxylic acids, but also of alkyl and aryl derivs. of pyrazole.

C. C. DAVIS

**Synthesis of 4-(3,4-dihydroxyphenyl)thiazoles.** TREAT B. JOHNSON and ELIZABETH GATEWOOD. *J. Am. Chem. Soc.* 51, 1815-9(1929).— $AcNHCH_2CN$  (20 g.) in 75 cc. abs. EtOH and 25 cc. concd.  $NH_4OH$ , cooled to  $10^\circ$ , was satd. with  $H_2S$ , giving 19 g. acetamidoacetothioamide, m.  $123-4^\circ$ ; with 3,4-(HO) $_2C_6H_3COCH_2Cl$  (I) this gives 2-acetamidomethyl-4-[3,4-dihydroxyphenyl]thiazole-HCl, crystg. with 1 EtOH, m.  $188-90^\circ$ ; digestion with concd. HCl gives 2-aminomethyl-4-[3,4-dihydroxyphenyl]thiazole-di-HCl, m.  $225-30^\circ$ . Acetylmethylaminoacetothioamide, m.  $156-7^\circ$ , in 16 g. yield by acetylating 20 g. of  $MeNHCH_2CN$ , dissolving in concd.  $NH_4OH$  and satg. with  $H_2S$ . The thioamide from  $Me_2(NH_2)CCN$ , m.  $185-6^\circ$ , with I gives 2- $\alpha$ -acetamidoisopropyl-4-[3,4-dihydroxyphenyl]thiazole, crystg. with 2  $H_2O$ , m.  $198-200^\circ$ ; HCl salt, m.  $188-9^\circ$ , the 2-amino deriv.-HCl, crystg. with 1  $H_2O$ , m.  $210-5^\circ$  (decompn.). The following 4-[3,4-dihydroxyphenyl]thiazoles were also prepd.: 2-acetylmethylaminomethyl-HCl, m.  $186-8^\circ$ ; 2-methylaminomethyl, crystg. with 1 EtOH, m.  $128-30^\circ$ ; HCl salt, m.  $220-5^\circ$ ; 2-mercapto, crystg. with 1  $H_2O$ , m.  $250^\circ$ ; 2-phenyl, m.  $164-5^\circ$ ; 2-amino-HCl, crystg. with 1  $H_2O$ , m.  $230-5^\circ$ ; 2-methylamino-HCl, m.  $275-80^\circ$ . These thiazoles are characterized by their stability in the air; all compds. thus far examd. are physiol active.

C. J. WEST

**Some derivatives of 4,5-naphtho-1,2-thiazole (naphth-1,2-thiazole).** R. STOLLÉ and W. BADSTÜBNER. *J. prakt. Chem.* [2], 121, 266-8(1929).—The ring system  $C_{10}H_8.CH:N:S$  is called 4,5-benzo-1,2-thiazole, and the corresponding  $C_{10}H_8$  derivs

are called 4,5-naphtho-1,2-thiazoles. The following compds. are described: 5,6-benzo-2,3-diketo-2,3-dihydrothionaphthene, red, m.  $171^\circ$ ; [4,5-(2',3'-naphtho)-1,2-thiazole] 3-carboxamide, (I), m.  $208^\circ$ ; acid, from I, yellow, m.  $197^\circ$  (decompn.); [4,5-(1',2'-naphtho)-1,2-thiazole]-3-carboxamide, brown, m.  $225^\circ$ .

M. A. DAHLEN

**Stability of diazonium salts of the triazole series.** JOSEPH REILLY and DENIS MADDEN. *J. Chem. Soc.* 1929, 815-6.— $NH_2C(NH)NHNH_2.HNO_3$  (I) (25 g.) was heated with 20 g. of  $EtCO_2H$  and a few cc. of  $H_2O$  for 24 hrs., followed by neutralization with  $K_2CO_3$  and evapn. to dryness. The residue was extd. with  $AcOEt$  and the soln. treated with concd.  $HNO_3$ , giving 17 g. of 5-amino-3-ethyl-1,2,4-triazole nitrate (II), m.  $167^\circ$  (after recrystn. from hot  $EtOAc-EtOH$  mixt.); the free triazole, m.  $152^\circ$ . II gave the following compds. upon diazotization and coupling: 5-azo- $\beta$ -naphthylamine, red, m.  $280^\circ$ . 5-azo- $\beta$ -naphthol, orange-red, m.  $180-1^\circ$ . 5-azoacetylacetone, yellow,

m. 236°; and 5-diazo-chloroaurate. The 3-isobutyltriazole (16 g.), m. 171°, corresponding to II, was prepd. in the same manner from 20 g. of isovaleric acid and 20 g. of I. The stability of triazolediazonium salts is increased by alkyl substitution, the effect increasing with the mol. wt. of the alkyl group.

A. S. CARTER

**Constitution of carthamin.** II. CHIKA KURODA. *Proc. Imp. Acad.* (Tokyo) 5, 82-5 (1929); cf. *C. A.* 23, 1906.—Carthamin, heated with dil.  $H_3PO_4$ , gives a mixt. of carthamidin (I),  $C_{15}H_{12}O_8$ , pale yellow, crystg. with 1  $H_2O$ , m. 218°, unstable, and isocarthamidin (II), isomeric with I, yellow, crystg. with 1  $H_2O$ , m. 238°. Various color reactions are given for I and II. I and  $Ac_2O$  with  $H_2SO_4$  give the  $\alpha$ -Ac deriv. (III), m. 158°; Ac deriv. (IV) of II, m. 180°. I or III with  $AcONa$  and  $Ac_2O$  at 125° gives the  $\beta$ -Ac deriv. of I, m. 143°. II or IV with  $AcONa$  and  $Ac_2O$  at 140-50° gives the  $\gamma$ -Ac deriv. of I, m. 179°. II is probably 5,6,7,8-tetrahydroxyflavanone. III,  $\beta$ -Carthamidin methyl ether and its synthesis. *Ibid.* 86.— $\beta$ -Acetylcarthamidin,  $Me_2SO_4$  and KOH in an atm. of H give the  $\beta$ -Me ether, m. 112°, identical with 2,3,4,6,4'-pentamethoxychalcone.

C. J. WEST

**Dissociation into free radicals of substituted dixanthyls.** V. The rate of dissociation. JAMES B. CONANT and MILDRED W. EVANS. *J. Am. Chem. Soc.* 51, 1925-35 (1929); cf. *C. A.* 21, 3055.—The rate of O absorption of dibutyl dixanthyl in PhBr at 25° has been measured by means of a differential pressure app. The reaction is of the 1st order until about 0.5 mole of O per mole of dixanthyl deriv. has been absorbed. The rate is independent of the concn. of the O in the soln. It thus appears that the rate-controlling step is the dissocn. of the dixanthyl deriv. into a free radical. The rates of dissocn. of the following dixanthyl derivs. in PhBr have been measured at different temps. by following the rate of O absorption: di-Me, di-Et, di-Pr, di-Bu, di-Am, di-iso-Am. The energy of activation has been calcd. from the temp. coeff. of the reaction velocity. A parallelism has been found between the rates of dissocn. and the temp. at which appreciable dissocn. first occurs as evidenced by the appearance of color in a dil. soln. The results are given in tables and curves.

C. J. WEST

**5,8-Dihydroxy- $\alpha$ -anthrapyridinequinones.** HARRY RAUDNITZ (WITH GRETE LAUBE). *Ber.* 62B, 509-13 (1929).—As might have been expected from the close relationship between phthalic and quinolinic acids, quinolinic anhydride (I) with  $C_6H_6$  and  $AlCl_3$  gives  $\beta$ -benzoylpicolinic acid which yields the N analog,  $\alpha$ -anthrapyridinequinone, of anthraquinone. This quinone, heated with NaOH and Zn dust, forms a deep blue soln decolorized by shaking with air, the presence of the pyridine ring in the anthraquinone complex apparently deepening the color as compared with anthraquinone. It seemed of interest, therefore, to prep. 5,8-dihydroxy- $\alpha$ -anthrapyridinequinone ( $\alpha$ -pyrquinizarin) (II) and 5,8-dihydro-6,7-benzo- $\alpha$ -anthrapyridinequinone (6,7-benzo- $\alpha$ -pyrquinizarin) (III), analogous to quinizarin (IV) and 1,4-dihydroxy-2,3-benzanthraquinone (V), resp., to det. the spectroscopic effect of the pyridine ring. This effect proved to be a distinct shifting of the max. of the absorption bands toward the red, as shown by the following values for these max. in KOH,  $H_2SO_4$ , and  $H_2SO_4$ - $H_3BO_3$ , resp.: IV, violet, 596.1, 553.7, 317.7; red, 548.3, 509.6, 476.4; red, 547.5, 508.8, 473.5. II, violet, 600.7, 561.5; crimson, 574, 532.2; pink, 547.5, 506.5, 473.5. V, violet, 584, 539, 505, orange, 540, 500, 469; yellow, 534, 496.5, 463. III, red-violet, 586.5, 544; yellow-red, 1-sided absorption beginning in the yellow; orange, 541.5, 503, 467. Whereas I with aromatic compds. and  $AlCl_3$  gives only ketopicolinic acids, with a  $Na-AlCl_4$  melt (1:5), it yields  $\alpha$ -anthrapyridinequinones directly with aromatic compds. contg. HO groups in the 1,4-positions, but, unlike  $C_6H_4(CO)_2O$ , it does not condense with  $o$ - $C_6H_4(OH)_2$ . IV, m. 198°, and V, dark red, m. 349°, were also obtained in very pure form from  $C_6H_4(CO)_2O$  and  $p$ - $C_6H_4(OH)_2$  and 1,4- $C_6H_4(OH)_2$ , resp., with  $Na-AlCl_4$ . II, dark red, sublimes *in vacuo*, m. 237°, isolated as the Na salt, dark blue-violet powder (yield, 44%). III, brown-red, sublimes *in vacuo* with partial decompn., m. 363°; Na salt, dark violet powder.

C. A. R.

**Substituted aromatic aldehydes in Hantzsch's pyridine condensation.** I. Methoxy-, chloro- and hydroxybenzaldehydes. LEONARD E. HINKEL and WM. R. MADEL. *J. Chem. Soc.* 1929, 750-4.—One mol. of  $p$ - $MeOC_6H_4CHO$ , 2 mols. of  $AcCH_3$ ,  $CO_2Et$  and 20 cc. of EtOH were satd. with  $NH_3$  and after standing 1 hr. were heated on a water bath for several hrs.; 65% of 2,6-dimethyl-3,5-dicarbethoxy-4- $p$ -methoxyphenyl-1,4-dihydropyridine (I), m. 159°, crystd. upon cooling. I was made into a paste with EtOH and  $N_2O_5$  passed in until a clear soln. resulted. The EtOH was removed by evapn., the residue was neutralized with  $Na_2CO_3$  soln. and extd. with  $Et_2O$ . 2,6-Dimethyl-3,5-dicarbethoxy-4- $p$ -methoxyphenylpyridine (II) crystd. upon evapn. of the  $Et_2O$  and after recrystn. from ligroin, m. 50°. In the same manner as in the case of I, the following similarly substituted dihydropyridines were prepd.: 4- $o$ -methoxyphenyl

(48%), m. 151°; 4-*m*-methoxyphenyl (33%), m. 120°; 4-*p*-chlorophenyl (69%), m. 149°; 4-*o*-chlorophenyl (38%), m. 132° (from aq. MeOH); 4-*m*-chlorophenyl (78%), m. 142° (from aq. MeOH); 4-*p*-hydroxyphenyl (49%), m. 227° (from EtOH); and 4-*m*-hydroxyphenyl (36%), m. 202°. No product could be obtained in the case of the *o*-HO deriv. Following a course analogous to the prepn. of II, the corresponding analogs of II were made: *o*-MeO, m. 65°; *m*-MeO, m. 82°; *p*-Cl, m. 68°; *o*-Cl, m. 62°; *m*-Cl, m. 53°; the HO derivs. formed nitroso compds. and could not be oxidized. From the theory of alternate polarities of Lapworth and Shoemith (C. A. 16, 3078) the negative substituents in the *o*- and *p*-positions should increase the activity of BzH and a similar group in the *m*-position should diminish it. This is not the case; comparing the yields, it is seen that they do not agree among themselves, for with the HO derivs. the *m*- is greater than the *o*-, and with the Cl-derivs., the *m*- is greater than either *o*- or *p*-. In all cases the activity of BzH (which gives 90% yields) is decreased by the substituents.

A. S. CARTER

Action of diazonium salts on 2,5-dimethyl-6-hydroxypyrazine. III. G. GASTALDI AND E. PRINCIVALLE. *Gazz. chim. ital.* 58, 679-82 (1928).—The expts. described show that 2,5-dimethyl-6-hydroxypyrazine (I) (C. A. 16, 101) reacts in a normal way with phenyl-, *p*- and *o*-tolyl diazonium salts, in the sense that the corresponding azo compds. have the constitution:  $\text{N}:\text{C}(\text{OH})\cdot\text{CMe}:\text{N}:\text{C}(\text{N}:\text{NR})\cdot\text{CMe}$ . They are stable, are

more acidic than the corresponding hydroxypyrazines and give stable cryst. salts. The ease with which I couples with the diazonium salts indicates that it reacts in the lactimic form, and possibly with alkyl halides it first forms *O*-ethers which are then transformed into *N*-derivs. (C. A. 23, 602). Preliminary expts. indicate that the product of the coupling of I and *p*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>N<sub>2</sub>Cl is not an azo compd. Coupling of I and PhN<sub>2</sub>Cl was carried out in an alk. medium, the alk. salt being then filtered, dissolved in water, decompd. with HCl, dried in air and recrystd. from EtOH, which gives a good yield of 3-phenylazo-2,5-dimethyl-6-hydroxypyrazine (II), orange-red, m. 208° (decompn.). Na salt, C<sub>11</sub>H<sub>11</sub>ON<sub>2</sub>Na, orange-red, by heating II with excess aq. NaOH and allowing to cool slowly. Prepd. in the same way, I and *p*-MeC<sub>6</sub>H<sub>4</sub>N<sub>2</sub>Cl give almost quant. 3-*p*-tolylazo-2,5-dimethyl-6-hydroxypyrazine, orange-yellow, m. 242° (decompn.). Na salt, C<sub>11</sub>H<sub>13</sub>ON<sub>2</sub>Na, orange-yellow. Likewise I and *o*-MeC<sub>6</sub>H<sub>4</sub>N<sub>2</sub>Cl yield 3-*o*-tolylazo-2,5-dimethyl-6-hydroxypyrazine, orange-yellow, m. 221° (decompn.). Na salt, C<sub>11</sub>H<sub>13</sub>ON<sub>2</sub>Na, orange-yellow.

C. C. DAVIS

Action of *o*-phenylenediamines upon dihydroxytartaric acid. FREDERICK D. CHATTAWAY AND WILLIAM G. HUMPHREY. *J. Chem. Soc.* 1929, 645-51.—When Na dihydroxytartrate is heated with aq. *o*-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub>, 2 mols. of the diamine react with 1 mol. only of the salt, forming quinoxaline-2,3-dicarboxy-*o*-phenylenediamide (I); Na dihydroxytartrate is only very sparingly sol. in H<sub>2</sub>O, and any excess above 1 mol. remains in suspension unchanged. When the filtered alk. soln. is partly neutralized with HCl, I seps. as a colorless cryst. powder, stable in neutral soln. and dissolving readily in cold dil. aq. alkali, from which it is reprecip. on addn. of a deficiency of acid. It dissolves in hot dil. HCl (1:50), but on cooling, the *o*-phenylenediamine salt (II) of quinoxaline-2,3-dicarboxylic acid (III) seps.; whereas, if it is dissolved in hot moderately concd. HCl (1:1), III seps. on cooling, *o*-phenylenediamine-HCl remaining in soln. The II and III may consequently be obtained directly from the original yellow condensation soln., the former by making the soln. weakly acid with HCl, and the latter by satg. it with gaseous HCl.

Attempts to acetylate or benzoylate I by the usual methods also cause decompn., with formation of the di-Ac or the di-Bz deriv. of *o*-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub>. Heated with Ac<sub>2</sub>O, III yields the anhydride, while dry NH<sub>3</sub> on this anhydride in C<sub>6</sub>H<sub>6</sub> suspension gives the NH<sub>4</sub> salt of 3-carbamylquinoxaline-2-carboxylic acid (IV), from which the acid itself may be obtained on acidification. This amic acid is converted into the corresponding imide (V) on being heated above its m. p., and into the Ac deriv. of the imide on boiling with Ac<sub>2</sub>O. On being heated above its m. p., III decomp., evolving CO<sub>2</sub> and yielding a small quantity (10%) of quinoxaline; better yields (30%) of this base are obtained by heating the NH<sub>4</sub> salt of the acid. In common with other N bases, quinoxaline forms a stable, well-crystd. monotetrachloroiodide. Similarly, Na chloroquinoxaline-2,3-dicarboxy-*p*-chloro-*o*-phenylenediamide, from which the *p*-chloro-*o*-phenylenediamine salt of 6-chloroquinoxaline-2,3-dicarboxylic acid, and the free acid

(VI) are obtained by heating with dil. and with concd. HCl, resp. *p*-Bromo-*o*-phenylenediamine gives the corresponding Br deriv. These halogen-substituted derivs. are considerably less sol. than the unsubstituted compds., and are therefore more readily prepd. and purified; otherwise their reactions are analogous. The following compds. were prepd. and characterized: I, m. 184° (decompn.). II, lemon-yellow, m. 186° (decompn.). III, prisms contg. 2 mols. H<sub>2</sub>O of crystn., m. 190° (decompn. after loss of H<sub>2</sub>O at 110°); *Et* ester, C<sub>14</sub>H<sub>14</sub>O<sub>4</sub>N<sub>2</sub>, prisms, m. 83°; *NH*<sub>4</sub> salt, m. 220–30°; *anhydride*, pale yellow prisms decomp. and charring 250–60°. IV, m. 190–5° (decompn.). V, pale yellow, m. about 260° (decompn.); *Ac* deriv., leaflets, m. about 220° (decompn.). Quinoxaline mono-tetrachloroiodide, C<sub>8</sub>H<sub>6</sub>N<sub>2</sub>·HICl<sub>4</sub>, m. 125–30° (decompn.). 6-Chloroquinoxaline-2,3-dicarboxy-*p*-chloro-*o*-phenylenediamide, C<sub>16</sub>H<sub>8</sub>O<sub>2</sub>N<sub>4</sub>Cl<sub>2</sub>, m. 207° (decompn.). (*p*-chloro-*o*-phenylenediamine salt, C<sub>16</sub>H<sub>12</sub>O<sub>4</sub>N<sub>4</sub>Cl<sub>2</sub>, m. 205° (decompn.)); 6-bromoquinoxaline-2,3-dicarboxy-*p*-bromo-*o*-phenylenediamide, m. 198° (decompn.). (*p*-bromo-*o*-phenylenediamine salt, m. 199° (decompn.)). VI, m. 175° (decompn.) (*anhydride*, m. 235–40° (decompn.)), *Et* H ester, m. 159°; *di-Et* ester, m. 60°; *NH*<sub>4</sub> salt, m. 215–25° (decompn.)). 6-Chloroquinoxaline, m. 60°. 6-Bromoquinoxaline-2,3-dicarboxylic acid, m. 172° (decompn.) (*anhydride*, m. 235–45° (decompn.)), *Et* H ester, m. 161°, *di-Et* ester, m. 69°, *NH*<sub>4</sub> salt, m. 235–40° (decompn.)). 6-Bromoquinoxaline, m. 56°. Pyrazine-tetracarboxylic acid (by oxidation of the anhydride of III), m. 205° (decompn.), *di-K* *di-H* salt is cryst., *tetra-Et* ester, m. 104°. W. O. E.

**Calycanthine. I.** The isolation of calycanthine from *Meratia praecox*. RICHARD H. F. MANSKE. *J. Am. Chem. Soc.* 51, 1836–9 (1929).—Calycanthine has been isolated from *Meratia praecox*, Rehd. and Wils., a shrub native to Asia, 4 kg. of seeds giving 70 g. alkaloid, identical with that from *Calycanthus floridus*, L. Two other alkaloids, m. 197–8°, and an oil, were isolated in small quantities, but have not been investigated. The existence of glucose, or a sugar which gives glucosazone, in the seeds has been shown. Xylose was isolated from the epicarp of the seeds by hydrolysis with dil. H<sub>2</sub>SO<sub>4</sub>. C. J. WESS

**Synthetical experiments on the aporphine alkaloids. V. Laurotetanine.** Syntheses of 2,3,6,7- and 3,4,6,7-tetramethoxyaporphines. ROBERT K. CALLOW, JOHN M. GULLAND AND ROBERT D. HAWORTH. *J. Chem. Soc.* 1929, 658–70.—Recent investigations have shown that isoglaucine (II), obtained by Gorter (*C. A.* 16, 2470) from laurotetanine (I) (R=OH, R'=MeO, the positions of which may be the reverse of that shown), is impure glaucine (III) and does not contain the vicinal homocatechol group in ring III. It occurred to the authors of this paper that this vicinal arrangement does not occur in the aporphine series and that a synthesis of 2,3,6,7-tetramethoxyaporphine (II) and 3,4,6,7-tetramethoxyaporphine (IV) would be of value in detg. the true nature of I. Synthesis of these compds. shows as expected that neither resembles isoglaucine. After some difficulty 6'-nitro-3',4'-dimethoxyphenylaceto-β-2,3-dimethoxyphenylethylamide (V), m. 144.5–5.5° (9.5 g.), was obtained by adding 6,3,4-O<sub>3</sub>N(MeO)<sub>3</sub>-C<sub>6</sub>H<sub>2</sub>CH<sub>2</sub>COCl, obtained from the corresponding acid (13.1 g.) and PCl<sub>5</sub> in CHCl<sub>3</sub>, to a mixt of 2,3-(MeO)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>CH<sub>2</sub>CH<sub>2</sub>NH<sub>2</sub> (12 g.) in CHCl<sub>3</sub> and dil. aq. NaOH. With PCl<sub>5</sub> in cold CHCl<sub>3</sub>, 19.5 g. of V was converted into 6 g. of 6'-nitro-3',4',5,6-tetramethoxy-1-benzyl-3,4-dihydroisoquinoline, m. 187.5–9.5°. The methiodide of this base, m. 146–8° (3.5 g.), was reduced by means of Zn dust and HCl to 2.2 g. of 6'-amino-3',4',5,6-tetramethoxy-1-benzyl-2-methyl-1,2,3,4-tetrahydroisoquinoline (VI), m. 233.5–5° (decompn.). A diazotized soln. of this compd. gave with an alk. β-naphthol a red ppt. of an azo dye. Diazotization of VI in MeOH-alc.-H<sub>2</sub>SO<sub>4</sub> gave *di*-2,3,6,7-tetramethoxyaporphine (II), pale yellow needles, m. 115.5–6.5° (0.55 g. from 1.94 g. of the *di*-HCl salt). A *hydriodide*, m. 227.5–30.5°, and a *methiodide*, m. 204–8°, were also obtained from II. Attempts to resolve II by means of *d*- and *l*-tartaric acids were unsuccessful. Colors with H<sub>2</sub>SO<sub>4</sub>, HNO<sub>3</sub>, Mandelin's, Fröhde's, and Erdman's reagents did not resemble those described by Gorter for isoglaucine. The yield of 6,3,4-O<sub>3</sub>N(MeO)<sub>3</sub>-C<sub>6</sub>H<sub>2</sub>CH<sub>2</sub>CO<sub>2</sub>H prepd. by the method of Oxford and Raper (*C. A.* 21, 1649) was increased from 60 to 77% by increasing the proportion of KOEt and (CO<sub>2</sub>Et)<sub>2</sub> to 6-nitrohomoveratrole. By the interaction of 2,3,4-O<sub>3</sub>N(MeO)<sub>3</sub>-C<sub>6</sub>H<sub>2</sub>CH<sub>2</sub>COCl from 19 g. of the corresponding acid (cf. Gulland and Haworth, *C. A.* 22, 2949) with 14 g. of β-2,3-dimethoxy-1-oxyphenylethylamine, 26 g. of 2'-nitro-3',4'-dimethoxyphenylaceto-β-2,3-dimethoxyphenylethylamide (VII), m. 95–6° was obtained. With PCl<sub>5</sub> in CHCl<sub>3</sub>, 4.5 g. VII gave 2.5 g. 2'-nitro-3',4',5,6-tetramethoxy-1-benzyl-3,4-dihydroisoquinoline (VIII), peach-colored prisms, m. 152–6°. The *methiodide*, m. 183–4° (decompn.); 6 g., reduced by Zn and HCl, gave 3.7 g. of 2'-amino-3',4',5,6-tetramethoxy-1-benzyl-2-methyltetrahydroisoquinoline (IX), m. 117.5–9.5°. A diazotized soln. of this amine in HCl gave with alk. β-naphthol scarlet azo dye. By diazotization of 3.72 g. IX in MeOH-alc.-H<sub>2</sub>SO<sub>4</sub>, 0.87 g. of

*dl*-3,4,6,7-tetramethoxyaporphine (IV) was obtained. The *dl*-base was purified by conversion to the *HI* salt, m. 257–62°. After regeneration from this salt it was crystd. from ligroin. The resolution of the *dl*-base by *d*- and *l*-tartaric acids gave *d*-3,4,6,7-tetramethoxyaporphine *H d*-tartrate, m. 174–85°, and *l*-3,4,6,7-tetramethoxyaporphine *H l*-tartrate, m. 170–80°. From these salts were isolated *d*-3,4,6,7-tetramethoxyaporphine, pale yellow, m. 125–5.5° [ $\alpha$ ]<sub>D</sub><sup>20</sup> 168° in CHCl<sub>3</sub> (*c* = 0.459), and *l*-3,4,6,7-tetramethoxyaporphine, m. 125.5–5.6° [ $\alpha$ ]<sub>D</sub><sup>20</sup> –167° in CHCl<sub>3</sub> (*c* = 0.978). The methiodide obtained from the *l*-base by heating with MeI, m. 208–10°. Color reactions of the aporphines are also summarized.

I. A. KOTEN

Acids resulting from the oxidation of brucine with chromic acid. HEINRICH WIELAND AND WILHELM MÜNSTER. *Ann.* 469, 216–24(1929).—Hanssen (*Ber* 17, 2849; 18, 777) reported an acid C<sub>16</sub>H<sub>18</sub>N<sub>2</sub>O<sub>4</sub> from the energetic oxidation of brucine and strychnine with CrO<sub>3</sub>, although later investigators could not obtain this product. It is now shown that, following exptl. conditions given in detail, 2 acids may be obtained, sepd. by crystn. from H<sub>2</sub>O. The acid C<sub>17</sub>H<sub>22</sub>N<sub>2</sub>O<sub>6</sub> crysts. with 5H<sub>2</sub>O, does not m. 345°, is readily sol. in hot H<sub>2</sub>O but slightly in H<sub>2</sub>O at 20° (1:140), [ $\alpha$ ]<sub>D</sub><sup>24</sup> 49.2° (0.591% soln. in H<sub>2</sub>O); titration indicates 1CO<sub>2</sub>H; *HCl* salt, crysts. with 2H<sub>2</sub>O, does not m. 320°; the *HBr* salt also crysts. with 2H<sub>2</sub>O; *chloroplatinate*, golden yellow, crystg. with 3H<sub>2</sub>O. The acid C<sub>16</sub>H<sub>20</sub>N<sub>2</sub>O<sub>4</sub> crysts. in 2 forms, with 2 and 4 mols. H<sub>2</sub>O, m. 311° (decompn.), soly. in H<sub>2</sub>O at 20° 1:6, [ $\alpha$ ]<sub>D</sub><sup>24</sup> –116.3° (1.062% soln. in H<sub>2</sub>O); titration indicates 1CO<sub>2</sub>H; *HBr* salt, crysts. with 1EtOH, decomp. 286°; *chloroplatinate*, golden yellow, crysts. with 5H<sub>2</sub>O. This may be the acid of Hanssen. C. J. WIST

New strychnine alkaloid. I. HEINRICH WIELAND AND GERHARD OERTEL. *Ann.* 469, 193–215(1929).—Vomicine (I), C<sub>22</sub>H<sub>24</sub>N<sub>2</sub>O<sub>4</sub>, the method of sepn. of which is not given, crysts. from 80% EtOH or Me<sub>2</sub>CO, [ $\alpha$ ]<sub>D</sub><sup>22</sup> 80.4° (0.398% soln. in EtOH), 1 g. dissolves in 70 cc. 80% EtOH at the b. p. and in about 55 cc. Me<sub>2</sub>CO; *HCl* salt, m. 245° (decompn.). CrO<sub>3</sub> in H<sub>2</sub>SO<sub>4</sub> gives a deep red soln. which is permanent for some time; HNO<sub>3</sub> (1:1) slowly gives a brown to orange-yellow color; heated with 10–20% MeOH-KOH till soln. results, there results an intense green color; acidified and FeCl<sub>3</sub> added, there results a splendid red-violet color. Heating 4 g. I in 10 cc. 20% MeOH-KOH in a N atm. for 0.5 hr. gives 3.9 g. vomicinic acid (II), sinters at 164° with loss of H<sub>2</sub>O and then m. 282°; heating with N HCl for 1 min. gives I; while II in alk. soln. is quickly oxidized by the air to a green dye, the acid soln. is stable toward O. I and BzCl give the *Bz* deriv., isolated only as the *HCl* salt, m. 182°. I. HCl and satd Br-H<sub>2</sub>O give a *Br* deriv., C<sub>22</sub>H<sub>22</sub>N<sub>2</sub>O<sub>4</sub>Br, m. 306°; heating 1 hr. with 20% MeOH-KOH gives bromovomicinic acid, m. 306°; this does not show the characteristic color reactions of II. I does not react with MeI even at 150°; Me<sub>2</sub>SO<sub>4</sub> gives an addn. product which, recrystd. from hot H<sub>2</sub>O, gives I *Me* sulfate, which loses H<sub>2</sub>O of crystn. at 100° and then m. 264° (decompn.). I, transformed into II as above and then treated with MeI, gives *N*-methylvomicinic acid, m. 254° (*HCl* salt, m. above 320°) and vomicinic acid betaine, C<sub>24</sub>H<sub>26</sub>N<sub>2</sub>O<sub>6</sub>, m. 210°, decomp. 230°. Catalytic reduction of I (Pt oxide) gives the dihydro deriv. (III), m. 290°; this does not react with MeI at 100°; dihydrobromovomicine, m. 280°. I, HI, red P and AcOH, heated 4 hrs., give desoxyvomicine, C<sub>22</sub>H<sub>24</sub>N<sub>2</sub>O<sub>3</sub>, catalytically reduced to a mixt. of 2 bases, C<sub>22</sub>H<sub>24</sub>N<sub>2</sub>O<sub>3</sub> (IV), m. 213°, and C<sub>22</sub>H<sub>24</sub>N<sub>2</sub>O<sub>3</sub> (V), m. 179°, sepd. by the greater soly. of V in MeOH. IV yields a methiodide, crystg. with 1H<sub>2</sub>O, m. 236° (decompn.). V gives a *Br* deriv., m. 159°. III, HI, red P and AcOH give iododihydrodesoxyvomicine, m. 242°, reduced by Zn and AcOH to dihydrodesoxyvomicine, m. 210°; the I is also split off by EtOH-KOH. Oxidation of 10 g. I in 240 cc. 4 N H<sub>2</sub>SO<sub>4</sub> with 21 g. CrO<sub>3</sub> in 105 cc. H<sub>2</sub>O at 70° gives the acid C<sub>16</sub>H<sub>18</sub>O<sub>4</sub>

$O_2N_2$ , m.  $304^\circ$  (decompn.), sublimes unchanged. Using 6 g. I and 21 g.  $CrO_3$  and starting the reaction at  $0^\circ$ , finally raising the temp. to  $90^\circ$ , there result 2 acids,  $C_{17}H_{22}N_2O_7$ , m.  $262^\circ$  (decompn.), crystg. with  $5H_2O$  and  $C_{17}H_{22}N_2O_8$ , m.  $312-4^\circ$  (decompn.), crystg. with  $3EtOH$ . C. J. WEST

The constitution of *l*- and *d*-pimaric and abietic acids. L. RUZICKA. *Bull. inst. pin* 1929, 112-22.—An address reviewing the present status of our knowledge of the constitution of these acids with bibliography of 45 references. A. P.-C.

Euphorbone from euphorbium resin. JULIUS A. MÜLLER. *J. prakt. Chem.* 121, 97-112(1929).—Details are given for the isolation of euphorbone, m.  $121.5-2.5^\circ$ ,  $[\alpha]_D^{16}$   $16.58^\circ$ .  $Ac_2O$  and  $AcONa$  give a mixt. of 2 acetates, sepd. by crystn. from  $Me_2CO$ ; euphorbol acetate(I), sinters  $85^\circ$ , m.  $90-1^\circ$ , clears  $98^\circ$ ,  $[\alpha]_D^{16}$   $11.34^\circ$ , is the principal product and is more sol. in  $Me_2CO$ ; novorbol acetate, m.  $123-4^\circ$ ,  $[\alpha]_D^{18}$   $-12.52^\circ$  (results in only a low % yield). Vitorbol, sinters  $120.5^\circ$ , m.  $122.5-123.5$  to  $125^\circ$ ,  $[\alpha]_D^{17}$   $12.85^\circ$ ; this may be simply a purified euphorbone; analysis indicates  $C_{27}H_{44}OH$  as its formula; novorbol,  $C_{26}H_{44}O$  or  $C_{26}H_{46}O$ , m. about  $150^\circ$ ,  $[\alpha]_D^{17}$   $29.61^\circ$ . Alk. sapon. gives a novorbol, m.  $123.5-4.5^\circ$ , which is optically inactive. I gives a *di-Br deriv.*, m.  $163-4^\circ$  (decompn.),  $[\alpha]_D^{17}$   $5.615^\circ$ . Vitorbol *p*-bromobenzoate, m.  $132-3^\circ$ ,  $[\alpha]_D^{19}$   $20.45^\circ$ ; novorbol deriv., m.  $183.5-4.5^\circ$ ,  $[\alpha]_D^{19}$   $18.88^\circ$ . C. J. WEST

Flavanone glucosides. IV. Naringin and hesperidin. Y. ASAHINA AND M. INUBESE. *J. Pharm. Soc. Japan* 49, 128-34(1929).—Naringin (I) when dried at  $110^\circ$ , m.  $171^\circ$  and has the compn.  $C_{27}H_{32}O_{14} \cdot 2H_2O$ . When recrystd. from  $H_2O$ , it has an addnl  $6H_2O$  of crystn. and m.  $83^\circ$ . The following equation is based on the detn. of the hydrolytic products of I:  $C_{27}H_{32}O_{14} + 2H_2O = C_{15}H_{18}O_5$  (naringenin) + glucose + rhamnose. When I in  $Ba(OH)_2$  soln. is heated 12 hrs. in  $H_2$  atms., it gives *p*- $HOC_6H_4CHO$  and phloroacetophenonerhamnoglucoiside (II),  $C_{26}H_{28}O_{13} \cdot H_2O$ , m.  $149-50^\circ$ ,  $[\alpha]_D^{21}$   $-86.51^\circ$ . Recrystn. from  $H_2O$  gives an addnl.  $4H_2O$  of crystn. Hydrolysis of II with dil.  $H_2SO_4$  gives phloroacetophenone, glucose and rhamnose. I and  $CH_3N_2$  give a syrupy substance which on hydrolysis gives isosakuranetin (5,7-dihydroxy-4'-methoxyflavanone). Since sakuranetin (5,4'-dihydroxy-7-methoxyflavanone) and  $CH_3N_2$  give 4',7-dimethoxy-5-hydroxyflavanone and the HO group at 5 is not methylated (cf. Asahina, *et al.* C. A. 22, 1592) as in the case of I, it is assumed that the sugar group in I is bound at the position 7. The hydrolysis of hesperidin (III) proceeds as follows:  $C_{28}H_{34}O_{15} + 2H_2O = C_{16}H_{14}O_6$  (hesperetin) + glucose + rhamnose. III and  $Ac_2O$  give the *di-Ac deriv.*, m.  $142-3^\circ$ ,  $[\alpha]_D^{21}$   $-32.9$ . Heating of III with  $Ba(OH)_2$  gives isoferrulic acid and a rhamnoglucoiside which on hydrolysis gives glucose, rhamnose and a substance giving the color reactions of 1,3,6-(HO) $_3C_6H_3$ . NAO UYEI

Alginate acid from *Macrocystis pyrifera*. WM. L. NELSON AND LEONARD H. CRETCHER. *J. Am. Chem. Soc.* 51, 1914-22(1929).—Extn. of *Macrocystis pyrifera* with  $EtOH$  gives 4-5% of mannitol. Details are given of the prepn. of alginate acid, which, by repeated dialysis, was obtained with 0.1% ash, mostly Fe. It is very slightly sol. in  $H_2O$ , liberates  $CO_2$  from carbonates and may be titrated with alkali to a definite end point. It does not reduce Fehling soln., but rapidly forms reducing substances if dried at  $100^\circ$  or if boiled with  $H_2O$  or dil. acid, considerable amts. of  $CO_2$  being liberated. The Na salt has  $[\alpha]_D^{20}$   $-133^\circ$ . On heating with 18%  $HCl$  it loses 24.65% as  $CO_2$ . Hydrolysis with distd.  $H_2O$ , dil.  $H_2SO_4$ , 80%  $H_2SO_4$  and  $HNO_3$  shows the acid to be a polymer of the anhydride of an aldehyde sugar acid in which all CHO groups are conjugated and all  $CO_2H$  groups free. The uronic acid could not be obtained cryst. With cinchonine it yields a salt, m.  $152^\circ$  (cor.); the salt of *d*-galacturonic acid m.  $158^\circ$ ;  $[\alpha]_D^{25}$  for the 2 products are  $113.6^\circ$  and  $134^\circ$ . Uronic acid may be oxidized to a dibasic  $C_6$  sugar acid. The diamide and diphenylhydrazide of this acid correspond in properties to the analogous compds. prepd. from *d*-mannosaccharic dilactone. C. J. WEST

Saponin of the sugar beet. K. REHORST. *Ber.* 62B, 519-34(1929).—See C. A. 23, 3357. C. A. R.

Constituents of corn cockle seed. II. Githagenin and githagic acid. E. WEDEKIND AND W. SCHICKLE. *Z. physiol. Chem.* 182, 72-81(1929); cf. C. A. 21, 384.—Further examn. of githagenin, the sapogenin of corn cockle seed, has led to the formula  $C_{27}H_{44}O_4$ .

instead of  $C_{25}H_{44}O_4$  previously reported, and for the oxidation product githagic acid  $C_{25}H_{42}O_5$  instead of  $C_{25}H_{42}O_6$ . Oxidation by  $CrO_3$  converts githagenin into githagic acid which is now shown to be a diketolactonemonocarboxylic acid. It forms a dioxime, and titrates monobasic in cold, dibasic in hot soln. Githagenin contains a lactone, a secondary alc. and a keto group, and is therefore a hydroxyketolactone. The OH or CO group is probably adjacent to a tertiary C common to 2 rings. Oxidation would then break the ring at the place of O or OH attachment and form the  $CO_2H$ , while the tertiary C would form CO. The Me ester of githagic acid may be distd. undecompd in a high vacuum; hence it is probable that the CO is not in  $\gamma$ - or  $\delta$ -position to the  $CO_2H$ . The instability of the acid toward boiling alc. KOH or a mixt. of HCl and AcOH suggests the occurrence in githagenin of OH and CO on the same ring and in  $\alpha$ - or  $\beta$ -position. The similarity of githagenin to the sapogenin  $C_{29}H_{44}O_6$  of *Chamellia japonica* (Aoyama, C. A. 23, 2445) and that of quillaic acid suggests a difference of 1OH and a common derivation of all 3 from the satd. hydrocarbon  $C_{29}H_{50}$  which would contain 5 hydrogenated rings.

Synthesis of low-boiling point hydrocarbons. W. GESSMANN and E. W. SHALDERS. *Brit.* 299,820, June 30, 1927. See Can. 282,392 (C. A. 22, 4128).

Hydrocyclic compounds. O. DIELS and K. ALDER (to I. G. Farbenind. A.-G.). *British* 300,130, Nov. 5, 1927. Hydrocyclic compds. are made by condensing a compd. having conjugated double bonds with a quinone or an unsatd. compd. such as an unsatd. aldehyde or acid. The double bond is opened up in the 1,4-position. Double-bond compds. mentioned include butadiene, cyclopentadiene, cyclohexadiene, myrcene, phellandrene, pyrrole and substituted pyrroles and furans; unsatd. compds. such as may also be used for the reaction include maleic acid or anhydride, itaconic anhydride, citraconic anhydride, acrylic acid, acrolein and ethylideneacetone. The products comprise terpenes, sesquiterpenes, alkaloids and camphors. Examples are given of the production of 3,6-endomethylene-*cis*- $\Delta^4$ -tetrahydrophthalic anhydride, *cis*- $\Delta^4$ -tetrahydro-*o*-phthalic anhydride, 3,6-endomethylene- $\Delta^4$ -tetrahydrobenzaldehyde, 3,6-endomethylene- $\Delta^4$ -tetrahydrobenzoic acid and the product of condensation of dihydrobenzene with maleic anhydride. 3,6-Endomethylenehexahydro-*o*-phthalic acid is made by hydrogenating the corresponding tetrahydro compd. in the presence of colloidal Pd; similarly *cis*- $\Delta^4$ -tetrahydro-*o*-phthalic acid yields hexahydro-*o*-phthalic acid.

Acylation of multivalent ether-alcohols. I. G. FARBENIND. A.-G. Fr. 652,383, April 7, 1928. Acyl groups are introduced into mixed multivalent ether-als. or their derivs., giving products which are solvents and swelling agents, particularly for nitrocellulose, or as substitutes for camphor in the manuf. of films. Examples are given.

Urethans of secondary alcohols. I. G. FARBENIND. A.-G. *Brit.* 300,177, Nov. 7, 1927. Urethans such as those of phenylethylmethylcarbinol, phenylethylethylcarbinol and ( $\alpha$ -allyl- $\beta$ -phenylethyl)methylcarbinol, possessing antipyretic properties, are prepd.

from the alc. in the usual manner as by treatment with carbamic acid chloride or by conversion into the chlorocarbonate by use of phosgene and subsequent treatment with  $\text{NH}_3$ . Phenylethylmethylcarbinol is made by the action of phenylethylmagnesium bromide on propionaldehyde, and ( $\alpha$ -allyl- $\beta$ -phenylethyl)methylcarbinol from allyl-benzylacetoacetic ester by ketonic decompn. followed by reduction.

**Ketols.** ANGELO KNORR and ALBERT WEISSENBORN (to Winthrop Chemical Co.). U. S. 1,714,378, May 21. Condensation of an aldehyde with a ketone is effected in the absence of water with use as condensing agent of an alkali metal compd. of a 1,3-ketol such as may be produced by treating the ketone which is to be condensed with anhyd. alkali metal hydroxide without heating. The aldehyde is gradually added while cooling. Examples are given of the production of diacetone alc. and hydracetyl-acetone, hexanol-4-one-2, octanol-5-one-3, crotylideneacetone, cinnamylideneacetone, ethylideneacetophenone, and *o*-ethylidenecyclohexanone.

**Phenols.** I. G. FARBERNIND. A.-G. Fr. 652,193, Apr. 4, 1928. Phenols are obtained by passing halogen derivs. of the aromatic series with steam over heated active  $\text{SiO}_2$ -gel, with or without metals or their compds. Examples are given. Cf. C. A. 23, 611.

**Arylaminoanthraquinones.** I. G. FARBERNIND. A.-G. Fr. 652,614, Apr. 12, 1928. Mixts of  $\alpha$ - and  $\beta$ -arylaminoanthraquinones or their derivs. are sepd. by treating them in an appropriate solvent with alkali metal hydroxides at a moderate temp. The  $\beta$ -compds. dissolve whereas the  $\alpha$ -compds. do not. Thus, impure 1-benzoylamino-8-chloroanthraquinone is heated to 45–50° in alc. soln. with KOH. The soln. obtained is found to contain  $\beta$ -benzoylaminochloroanthraquinone.

**Hydroxythionaphthenes.** I. G. FARBERNIND. A.-G. Fr. 652,049, Mar. 31, 1928. Hydroxythionaphthenes are prepd. by heating with aq. alkali *o*-thioglycolic acids of arylcarboxamides which are obtained by acid sapon. agents on cyanoaryl-*o*-thioglycolic acids. In examples 2-cyano-3-methyl-5-chlorobenzene-1-thioglycolic acid is heated with  $\text{H}_2\text{SO}_4$  to 95–100° for 5 hrs. giving 2-carbamyl-3-methyl-5-chlorobenzene-1-thioglycolic acid (I), m. 172–174°. Similarly, 5-methoxy-2-cyano-1-thioglycolic acid is converted to 5-methoxy-2-carbamyl-1-thioglycolic acid, m. 208–210°. I is heated with NaOH and  $\text{Na}_2\text{CO}_3$  to 80° for 7 hrs., and the hydroxythionaphthencarboxylic acid which is pptd. is oxidized to 4,4'-dimethyl-6,6'-dichloroindigo. Similarly, 5-ethoxybenzene-2-carbamyl-1-thioglycolic acid is converted to 6-ethoxy-3-hydroxythionaphthene and 6,6'-diethoxyindigo.

**Alkyl phosphates.** I. G. FARBERNIND. A.-G. Brit. 300,044, Jan. 12, 1928. Reaction is effected between alcs. and P oxychloride while continuously removing HCl from the reaction mixt. by heating or reduction of pressure. Diluents such as  $\text{CHCl}_3$ ,  $\text{C}_6\text{H}_6$ , or an excess of the alc. may be used as may also catalysts such as Cu or metal chlorides. An example is given of the treatment of Bu alc. to form tri-Bu phosphate and the use of EtOH, iso-Bu alc. or primary AmOH also is mentioned.

**Formates.** I. G. FARBERNIND. A.-G. Fr. 652,597, Apr. 12, 1928. See U. S. 1,698,573 (C. A. 23, 1138).

**Benzanthrone and derivatives.** BERTHOLD STEIN, WILLY TRAUTNER and ROBERT BERLINER (to Grasselli Dyestuff Corp.). U. S. 1,713,565, May 21. Benzanthrone is formed by heating to about 100° cinnamylideneanthrone in a melt of anhyd.  $\text{AlCl}_3$  and NaCl. A product which is probably a chlorobenzanthrone is similarly obtained from cinnamylidene- $\alpha$ -chloroanthrone, and a  $\beta$ -chlorobenzanthrone is obtained from cinnamylidene- $\beta$ -chloroanthrone.

**Piperidine derivatives.** SAMUEL M. McELVAIN. U. S. 1,714,180, May 21. Compds. such as a 1-alkyl-3-carbalkoxy-4-piperidyl benzoate or other compds. of the

general formula  $\text{RN}.\text{CH}_2.\text{CH}(\text{CO}_2\text{R}').\text{CH}(\text{OCOR}^2).\text{CH}_2.\text{CH}_2$  in which R and R' represent alkyl groups and R<sup>2</sup> an aromatic group, are formed by causing a reaction between a primary alkylamine and alkyl  $\beta$ -halopropionate, sepg. the  $\beta,\beta'$ -dicarbalkoxy-diethylalkylamine thus produced and condensing it by heating with a condensing agent adapted to eliminate a mol. of alc., thus forming 1-alkyl-3-carbalkoxy-4-piperidone, treating the latter with a reducing agent to convert the ketone group into an alc. group, acylating with an agent contg. a nitro-substituted phenyl group, reducing the nitro group and alkylating the resulting primary amino group. 1-Isoamyl-3-carbethoxy-4-piperidyl benzoate-HCl, m. 181°; 1-amyl-3-carbethoxy-4-piperidyl benzoate-HCl, m. 166; 1-amyl-3-carbethoxy-4-piperidone-HCl, m. 143°; 1-butyl-3-carbethoxy-4-piperidyl benzoate-HCl, m. 177°, and the corresponding piperidone-HCl, m. 129°; 1-isobutyl-3-carbethoxy-4-piperidyl benzoate-HCl, m. 199°, and the corresponding piperidone-HCl, m. 126°; 1-isoamyl-3-carbethoxy-4-piperidyl *p*-aminobenzoate-di-HCl,

m. 215°; 1-isobutyl-3-carbethoxy-4-piperidyl *p*-aminobenzoate-di-HCl, m. 232°, and the hydrochloride of the *p*-nitrobenzoate, m. 206°; 1-butyl-3-carbethoxy-4-piperidyl *p*-aminobenzoate-di-HCl, m. 230°, and the hydrochloride of the *p*-nitrobenzoate, m. 194°. Some of the compds. are suitable for use as *local anesthetics*. Numerous details of their prepn. are given.

**Organic hydroxy acids from nitriles.** I. G. FARBENIND. A.-G. Brit. 300,040, Dec. 28, 1927. Production of  $\alpha$ -hydroxycarboxylic acids by the acid saponification of the corresponding nitrile is effected with a sufficient quantity of water in the presence of an inert org solvent such as dioxane, ethyl ether,  $C_2H_5Cl$ , or  $CHCl_3$  capable of dissolving the reagents and reaction products except the resulting  $NH_4$  salt. The nitriles used may be prepd. in the same solvent used for the saponification. Examples are given of the production of lactic, mandelic and  $\alpha$ -hydroxybutyric acids.

**Carbamylaryl-*o*-thioglycolic acid.** I. G. FARBENIND. A.-G. Fr. 651,843, Mar. 28, 1928. *o*-Cyanoarylsulfonyl chlorides are reduced so as to transform the sulfonyl chloride group into a mercaptan, and at the same time the CN group into a carbamyl group and condensed with monochloroacetic acid. Thus, 1-methyl-2-amino-5-chlorobenzene-3-sulfonic acid is transformed into 1-methyl-2-cyano-5-chlorobenzene-3-sulfonic acid by Sandmeyer's reaction, the latter is dissolved in  $C_2H_5$ , and Zn dust is added slowly. The mass is stirred at 60° for 1 hr., cooled and HCl and Zn dust are added, after some hrs. the transformation to 1-methyl-2-carbamyl-5-chlorobenzene-3-mercaptan is complete. This is dissolved in NaOH soln. and condensed with monochloroacetic acid, giving 1-methyl-2-carbamyl-5-chlorobenzene-3-thioglycolic acid, m. 172-4°. When boiled with dil. NaOH soln. the amino group is split off and 1-methyl-2-carboxy-5-chlorobenzene-3-thioglycolic acid, m. 166°, is obtained. The prepn of 1-ethoxybenzene-4-carbamyl-3-thioglycolic acid, m. 208-10°, 1-ethoxy-4-carboxybenzene-3-thioglycolic acid, m. 218°, 4-chlorobenzene-1-carbamyl-2-thioglycolic acid, m. 206°, and 4-chloro-1-carboxybenzene-2-thioglycolic acid is also described.

***o*-Acylbenzoic acid compounds.** JOHN M. TINKER and IVAN GUBELMANN (to Newport Co.). U. S. 1,713,569, May 21. In producing *p*'-chloro-*o*-benzoylbenzoic acid from the reaction mass resulting from the condensation of phthalic anhydride with PhCl in the presence of  $AlCl_3$  and contg. an org. Al compd. and an excess of PhCl, or in the similar production of other aromatic acylbenzoic acid compds., the reaction mass is charged into cold water, maintained at a temp. of about 25° and allowed to form a 3-layer system including an upper aq. layer contg. most of the  $AlCl_3$ ; this aq. layer is sepd., and the remaining 2-layer system is made alk. and subjected to steam distn. Numerous details of procedure are described.

**Benzoic acid from phthalic anhydride and similar reactions.** ALPHONS O. JAEGER (to Selden Co.). U. S. 1,714,956, May 28. Phthalic anhydrides or their derivs. such as esters or other dicarboxylic acids or their derivs. are passed over catalysts which favor the splitting of carboxy groups in the presence of H, H-contg. or other reducing gases, such as illuminating gas, natural gas, etc., or vapors, such as MeOH, Me formate, etc. Good yields of the corresponding monocarboxylic acids or their derivs. are obtained and there is practically no loss, for the H or reducing gases can be recirculated and any unreacted polycarboxylic acid substance can be easily sepd. from the monocarboxylic acid substance formed and reused. The products obtained will vary with the ratio of H or other reducing gases, the reaction temp., time of contact and with the catalyst. Thus it is possible to obtain from phthalic anhydride a high percentage of benzoic acid under suitable conditions and in some cases the only by-products are small amts. of benzaldehyde and occasionally benzyl alc., which can be readily sepd. Under suitable reaction conditions, and with catalysts which favor reduction, larger proportions of aldehydes and other reduction products are obtained. Numerous examples and details are given.

**Acetic acid.** SOC. ANON. DES DISTILLERIES DES DEUX-SEVRES. Brit. 300,246, Nov. 10, 1927. In extn. of HOAc from its aq. solns. by a solvent such as AmOAc having a b. p. higher than HOAc but below 150° followed by the dehydration of the ext. by distg. with an entraining liquid such as EtOAc, as described in Brit. 296,974 (C. A. 23, 2449), the heating of the liquids in the column in which the entraining liquid and water are distd. off is effected by heat of the vapor of HOAc from the still in which it is sepd. from the solvent. Various details of app. are described.

**Concentrating acetic acid by multiple stage distillation.** HERMANN SUIDA. U. S. 1,715,313, May 28. Aq. HOAc soln. is distd. in successive stages at successively decreasing pressures, and the resulting mixed HOAc and  $H_2O$  vapors from each stage are subjected to extn. with an extn. agent such as described in U. S. 1,621,441 (C. A. 21, 1464) or U. S. 1,624,810 (C. A. 21, 1819) of higher b. p. than HOAc; the ext. is

drawn off and the water vapors substantially freed from HOAc, from each stage, are used for heating the dil. HOAc soln. in the next succeeding stage. An arrangement of app. is described. Cf. C. A. 23, 2449.

**Purifying sulfonic and naphthenic acids.** NAAMLOOZE VENNOOTSCHAP DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Brit. 300,264, Nov. 11, 1927. Purification is effected by pptn. from their aq. solns. either in the form of the acids themselves or of their salts by adding a volatile electrolyte such as HCl, HNO<sub>3</sub>, HOAc or NH<sub>3</sub>; impurities remain in soln. Various details and examples are given.

**Acid anhydrides.** CONSORTIUM FÜR ELEKTROCHEMISCHE INDUSTRIE GES. Fr. 652,078, April 2, 1928. Carboxylic acid anhydrides are prepd. from a vinyl ester and a carboxylic acid by heating them in the presence of H<sub>2</sub>SO<sub>4</sub>, H<sub>3</sub>PO<sub>4</sub>, benzenesulfonic, sulfoacetic or other acid, and an acid salt or neutral salt such as Hg<sub>2</sub>SO<sub>4</sub>. AcH formed may be sepd. by distn. The reaction may be made continuous. Mixed anhydrides such as acetopropionic anhydride from vinyl acetate and propionic acid and butyroatetic anhydride from vinyl butyrate and AcOH may be prepd.

**Catalysts for methanol synthesis.** BRITISH CELANESE, LTD., W. BADER AND S. J. GREEN. Brit. 300,142, May 2, 1927. Catalysts for MeOH synthesis are prep. by pptg. ZnCO<sub>3</sub> in gelatinous form, washing and drying the ppt. so that it retains its colloidal state, and heating the gel at a temp. not exceeding that employed in the MeOH synthesis. Protective colloids also may be used and various details and examples are given.

**Glycerol.** J. W. LAWRIE (to E. I. duPont de Nemours & Co.). Brit. 300,254, Nov. 11, 1927. In effecting distn. by atomizing glycerol slop in the presence of a hot gaseous medium, the surface of the still in contact with the glycerol is formed of material not having a more active catalytic action on the glycerol than that of the solids normally present in the slop. Cu, Al, "monel metal" or enameled surfaces may be used.

**Acetaldehyde.** WILLY O. HERRMANN and HANS DEUTSCH (to Consortium für Elektrochemische Industrie). U. S. 1,714,783, May 28; Fr. 651,728, Mar. 24, 1928. See Brit. 288,213 (C. A. 23, 609).

**Chloroacetaldehyde.** I. G. FARBENIND. A.-G. Brit. 299,722, Oct. 28, 1927. Chloroacetaldehyde, produced as described in Brit. 299,319 (C. A. 23, 3235) may be sepd. from the aq. HCl produced by a single distn. after bringing up the HCl in the soln. to 20% by adding or forming HCl in the soln. A 70–80% concn. of chloroacetaldehyde may be obtained in a suitable column still and by passing the vapors leaving the column over CaCl<sub>2</sub> at 100° the chloroacetaldehyde may be obtained pure and in 85–90% yield. The residue is distd. without a column and introduced into the next operation.

**Formaldehyde sulfoxylate.** CURT SCHUMANN, EDUARD MÜNCH, OTTO SCHLICHTING and BRUNO CHRIST (to Grasselli Dyestuff Corp.). U. S. 1,714,636, May 28. Formaldehyde bisulfites are subjected "under energetic conditions" and in the presence of a hydrogenating catalyst such as Ni on kieselguhr to the action of a reducing gas, e. g., H under 120 atm. pressure at 50° for 40 hrs. U. S. 1,714,637 specifies production of aldehyde sulfoxylates contg. at least 2 C atoms in a similar manner from the corresponding aldehyde bisulfites.

**Acetone.** CONSORTIUM FÜR ELEKTROCHEMISCHE INDUSTRIE GES. Brit. 299,720, Oct. 29, 1927. HOAc vapor is passed over a catalyst such as one comprising a Ce compd., at such a speed that only part of the HOAc can be converted into acetone; unchanged HOAc may be sepd. from the acetone and returned to the process. Inert gases such as steam, CO<sub>2</sub> or N also may be added and the increased heat consumption may be compensated for by preheating the HOAc vapor to about 300°. Cf. C. A. 23, 3235.

**Flavanthrone.** WILLIAM SMITH and JOHN THOMAS (to Scottish Dyes, Ltd.). U. S. 1,714,249, May 21. A 1-halo-2-anthraquinonyl urethan compd. such as a 1-chloro-compd. is converted into flavanthrone by heating with finely divided Cu.

**1-Phenylbenzanthrone, etc.** WILLY TRAUTNER, ROBERT BERLINER and BERTHOLD STEIN (to Grasselli Dyestuff Corp.). U. S. 1,713,571, May 21. 1-Phenylbenzanthrone is formed by heating cinnamylideneanthrone (suitably in the presence of an inert liquid of high b. p. such as a molten mixt. of KOAc and NaOAc) to a temp. of about 250°. The 1-phenylbenzanthrone crystallizes from glacial HOAc or from PhCl as yellow needles, m. 181°. Substituted cinnamylideneanthrones such as  $\alpha$ - or  $\beta$ -chloro, methyl or hydroxy derivs. react likewise by heating to 250–260° in presence or absence of a solvent or suspension agent to form the corresponding 1-phenylbenzanthrone compds.

**10-Phenylbenzanthrone, etc.** ROBERT BERLINER, BERTHOLD STEIN and WILLY TRAUTNER (to Grasselli Dyestuff Corp.). U. S. 1,713,591, May 21. By treating

1-phenylbenzanthrones (which may be produced as described in U. S. 1,713,571; cf. preceding abstr.) with an acid condensing agent (such as with anhyd.  $\text{AlCl}_3$  and  $\text{NaCl}$  at 100–150°), isomeric compds. are obtained. The 10-phenylbenzanthrone forms yellow needles, m. 199–200°.

**Amyl chloromalonamide.** ARTHUR W. DOX (to Parke, Davis & Co.). U. S. 1,713,822, May 21. This compd. is a white cryst. substance, m. 134–5°, has powerful sweetening properties, and may be made by a three-stage process with intermediate production of ethyl amyl malonate and amyl malonamides.

**Condensation products of the benzanthrone series.** GEORG. KRÄNZLEIN and MARTIN CORELL (to Grasselli Dyestuff Corp.). U. S. 1,714,677, May 28. By heating benzoates of 2-hydroxy- or 2,6-dihydroxynaphthalenes to a temp. between about 100° and about 200° in the presence of  $\text{AlCl}_3$  while introducing O, new condensation products are obtainable. With the benzoate of  $\beta$ -naphthol there is obtained  $\alpha$ -hydroxybenzanthrone; with the dibenzoate of 2,6-dihydroxynaphthalene the hitherto unknown 1,6-dihydroxy-3,4,8,9-dibenzopyrenequinone is obtained.

FRANK P. UNDERHILL

**Ricinus lipase.** I. (a) Hydrolysis of esters and of beeswax. (b) Hydrolysis of carbohydrates. A. PIUTTI AND E. DE CONNO. *Ann. chim. applicata* 18, 468–78 (1928).—An industrial prepn. hydrolyzes, not only glycerides, but also, almost quantitatively, other esters and to some extent, sucrose and starch. Cf. following abstr. B. C. A.

**Ricinus lipase.** II. Hydrolysis of lecithin. A. PIUTTI AND E. DE CONNO. *Ann. chim. applicata* 18, 512–20 (1928).—Using *Ricinus* lipase as furnished by the "Sirio" soap and perfume manufacturers, the authors were unable to hydrolyze lecithin to more than about 25%, although the seeds of *Ricinus* plants will complete the hydrolysis. Evidently, the manufd. product lacks something which the natural product has. This may be the glycerophosphatase of Plimmer. III. Hydrolysis of phytin. *Ibid.* 520–7.—Phytin was hydrolyzed with the manufd. *Ricinus* lipase and the amt. hydrolyzed detd. by means of P detns. The hydrolysis only proceeded to about 2%. On repeating with freshly prepd. lipase, the hydrolysis was only about 1%. On repeating again with the *Ricinus* seeds the hydrolysis was 5.7%, indicating the presence of phytase. Cf. preceding abstr. A. W. C.

**Relations between chemical constitution and physiological properties.** S. BERLINGOZZI. *Giorn. chim. ind. applicata* 10, 555–7 (1928).—A review of recent work on this subject as well as a brief summary of methods of analysis of pharmaceutical products.

A. W. CONTIERI

**Biological properties of the protein constituents of serum.** II. Hemolytic properties of albumin and globulin from hemolytic serum. V. SCAFFIDI. *Riv. patol. sper.* 3, 265–70 (1928); *Physiol. Abstracts* 13, 569.—The hemolytic properties are retained in the albumin fraction, not in the globulin of the serum. H. L. D.

**Preparation of the crystalline potassium salts of hydroxyhemin.** A. HAMSÍK. *Z. physiol. Chem.* 182, 117–24 (1929).—Crystals of the tri-K salt of  $\alpha$ -hydroxyhemin are readily obtained by suspending  $\alpha$ -hydroxy- or  $\alpha$ -chlorohemin in MeOH, then adding sufficient KOH in MeOH to effect soln. and finally an equal vol. of 20% KOH in MeOH. After 6 hrs. the crystals are filtered and washed with MeOH- $\text{Et}_2\text{O}$ . Only the  $\alpha$ -modification of chloro- or hydroxyhemin gives a good yield of the K salt; the  $\beta$ - and pseudo-forms give smaller yields and the crystals are indistinct. In the transition from  $\alpha$ - to  $\beta$ - or pseudo-form it is probable that the 3rd active H and especially the further less active H atoms are lost. The more feebly active H atoms are probably necessary also for anhydride formation and for Cl linkage, since only the  $\alpha$ -modification can form anhydride or bind Cl firmly. They probably function also in protoporphyrin formation, since the pseudo modification yields no protoporphyrin. The  $\beta$ -modifications in many instances appear to be mixts. of  $\alpha$ - and pseudo-forms. A. W. DOX.

**Fractionation of the partial hydrolyzates of proteins.** K. FELIX AND A. LANG. *Z. physiol. Chem.* 182, 125–40 (1929).—An exchange of bases is readily effected between the salts of diamino acids and the Na of permittite. These substances behave as mono-acid bases and the extent of exchange is detd. by the abs. amt. of base present and not

by the concn. of the soln. With arginine, an equil. was reached in 5 hrs. at 32°, where more than  $\frac{1}{2}$  of the org. base had been exchanged, 80% of this reaction having occurred in the first 10 mins. In the equation,  $[(b-x)/x] [(a-x)/x]^\beta = K$ ,  $a$  = initial quantity of arginine,  $b$  = Na present in permutite,  $x$  = ions of each exchanged. Expressed in logarithms, the equation becomes

$$\log \frac{b-x}{x} = \beta \left( \log \frac{x}{a-x} \right) + \log K.$$

By plotting the values of  $\log \left( \frac{b-x}{x} \right)$  as ordinates and those of  $\log \left( \frac{x}{a-x} \right)$  as abscissas, the curve obtained is a straight line, the tangent of whose angle of inclination toward the abscissa gives the value for  $\beta$ . The const.,  $K$ , represents the point of intersection of the curve with the ordinate. The curves for different substances vary according to the angle  $\beta$  and the const.  $K$ . Values detd. for  $\beta$  are:  $\text{NH}_4$  0.717, arginine 0.6055, histidine 0.3075, ornithine 0.2652; and for  $K$ : histidine 54.2, arginine 45.8, ornithine 42.02,  $\text{NH}_4$  0.61. The smaller the value of  $K$  the more easily is the exchange effected. Thus,  $\text{NH}_4\text{Cl}$  easily expels any of the histone bases from the permutite. From a mixt. of arginine and ornithine, the latter is taken up more readily by the permutite and a fair sepn can thus be effected. The amt. of absorption is measured by Kjeldahl N detn. of the soln. before and after shaking with permutite. An attempt was made to fractionate a peptic hydrolyzate of gelatin by successive filtrations at  $p_H$  6.7 through 50 g. portions of permutite. After the 8th filtration no further absorption occurred. Each fraction was then extd. from the permutite by satd.  $\text{KCl}$  and analyzed. Although no fraction represented an individual substance, the compn. of the various fractions differed considerably, especially as regards the relative amts. of arginine, histidine and lysine contained therein.

A. W. DOX

**Hemin compounds.** RAPHAEL ED. LIESEGANG. *Pharm. Zentralhalle* 69, 497-9 (1928).—The functions of hemin in respiration are discussed in connection with Warburg's and other investigators' views on the subject of hemoglobin and globin. Attention is directed also to the combination of hemin with nicotine as being an example of a true catalyzer, whereas hemoglobin (hemin + globin) really functions as a transport agent rather than as a catalyzer.

**Biophysical chemistry. I.** VICTOR COFMAN. *J. Chem. Education* 6, 858-67 (1929)

W. D. LANGLEY

The effect of local changes in temperature on gas tensions in the tissues. H. C. BAZETT AND L. SRIBYATTA. *Am. J. Physiol.* 86, 565-77 (1928).—Gas mixts. (20 cc.) were injected under the skin of the forearm, the arm was immersed to the elbow in water at varying temps. and samples of gas were removed from time to time for analysis. The effect of temp. on equil. conditions of  $\text{CO}_2$  and  $\text{O}_2$  was considerable.

J. F. L.

The effect of local changes in temperature on blood from the hand veins. L. SRIBYATTA AND H. C. BAZETT. *Am. J. Physiol.* 86, 578-86 (1928).—Blood drawn from the veins of the hand, after immersion of the arm in water at varying temps., was analyzed for  $\text{O}_2$ ,  $\text{CO}_2$  and  $p_H$ . The gas tensions, calcd. from the blood data, agreed roughly with those in the tissues as detd. by the gas-equil. method (preceding abstr.). The cooling of a limb caused the blood to have a much lower  $\text{O}_2$  tension, a lower  $\text{CO}_2$  tension, and a slight shift in acidity toward the neutral point.

J. F. LYMAN

Changes in the blood resulting from mechanical obstruction of the hepatic veins. J. P. SIMONDS AND W. W. BRANDES. *Am. J. Physiol.* 86, 623-7 (1928).—When the outflow of blood from the liver was blocked by mechanically constricting the hepatic veins, blood pressure fell 40-60 mm.; blood concn. decreased about 11%, with a gradual increase back to normal at the end of 15 mins.; coagulation time decreased followed by an increase upon release of the constriction; blood sugar fell about 42% during constriction for 15 mins. with a rapid rise on release.

J. F. LYMAN

The effects of bicarbonate buffers and of carbon dioxide on the motor functions of the excised small intestines of rabbits. TORALD SOLLMANN, W. F. VON OERTINGEN AND Y. ISHIKAWA. Western Reserve Univ. *Am. J. Physiol.* 86, 661-74 (1928); cf. *C. A.* 22, 3424.—The addn. of  $\text{NaHCO}_3$  in Locke's soln. up to 0.08% stimulated the muscles of rabbit's intestine placed therein. Bicarbonate stimulation was due to  $\text{HCO}_3$  ions and independent of  $p_H$ .  $\text{CO}_2$  addns., within the  $p_H$  range of 8.2 to about 6.8, had but little effect on intestinal movements. Serious depression began at about  $p_H$  6.4 and arrested movements occurred generally between 6.2 and 6.0.

J. F. LYMAN

Water retention under low barometric pressure. C. S. SMITH. *Am. J. Physiol.* 87, 200-7 (1928).—A fall in barometric pressure of 2.6 to 9.8 cm. Hg during a period of

12 to 48 hrs. was accompanied by a retention of  $H_2O$  in the bodies of dogs and rats subjected thereto.

**J. F. LYMAN**  
The difference in osmotic concentrations between egg yolk and white of egg. **JAN STRAUB.** *Rec. trav. chim.* 48, 49-82(1929).—The f. p. of egg yolk is  $-0.60^\circ$  and of egg white  $-0.45^\circ$ . The concns. of Na, K, Cl, lactate and other univalent ions, glucose and unknown undissocd. mols. were detd. in egg yolk and white and found to be different and to bear no const. ratio to each other in the different parts of the egg. The calcn. and measured f. p. depressions agree. If the white and yolk of the egg were in equil., an osmotic pressure of 1.8 atm. must exist across the membrane dividing the 2 parts. This is a greater mech. pressure than the membrane can stand without rupture so the 2 cannot be in equil. The osmotic concn. of the egg did not alter, however, on keeping 42 days. A stationary state is suggested to exist which is maintained by the continual performance of work by the oxidation of glucose. The energy required is 0.01 calories per day. When the egg is killed by freezing or poisoning, the osmotic pressures inside and outside the egg yolk tend to become equal. The mechanism by which glucose oxidation furnishes the energy for electroendosmose to maintain the stationary state is discussed.

**J. G. McNALLY**  
Further studies on the solubility of urinary uric acid. **RUGGERO ASCOLI.** *Riv. chim. terap. sper.* 16, 33-46(1929); cf. *C. A.* 23, 163, 168.—The comparative soly. of synthetic and urinary uric acid in normal urine was studied. The  $p_H$  of fresh urine was detd. and then divided into 2 equal pts. One was continuously agitated for  $\frac{1}{2}$  hr. with an excess of uric acid (1 g. of uric acid per 100-200 cc. of urine); the other served as a control. Both portions were filtered through paper, preserved with  $CHCl_3$ , and allowed to stand 24 hrs. The formation of any ppt. was noted and the uric acid was detd. by the Folin-Shaffer method. Results: (1) Alk. and neutral urines dissolved appreciable amts. of synthetic uric acid. (2) Slightly acid urines,  $p_H$  6.5-7.0, do not dissolve any uric acid. (3) Strongly acid urines,  $p_H$  5.5-6.5, when agitated with synthetic uric acid produce a ppt. which consists of urinary uric acid, an amt. equal to about 10% of the total uric acid in the urine. (4) The amt. of synthetic uric acid which dissolves in alk. urines is not directly dependent on the  $p_H$  but is inversely proportional to the urinary uric acid content. (5) The addn. of crystals of uric acid to acid urines with a high uric acid content produces a ppt. of uric acid equal to only 7% of the total. If the uric acid in the urine existed in the form of a supersaturated soln., the addn. of the uric acid crystals should have pptd. all the uric acid dissolved in excess. Failure to do so shows that only about 7% of urinary uric acid is in a state of supersatn. (6) When the alk. urines are agitated with synthetic uric acid and treated with the U acetate reagent, a typical characteristic flocculent ppt. is formed which is distinctly different from that which is formed with normal urines. Conclusion: The difference in behavior of urinary and synthetic uric acid indicates that the 2 are chemically different; the former probably exists in some form of mol. complex with special properties. The soly. of uric acid is, therefore, governed by factors that are essentially chem.

**P. M.**  
Studies on chronaxia. II. The action of magnesium on the chronaxia of the neuro-muscle preparation. **P. S. ISRAEL.** *Boll. soc. ital. biol. sper.* 4, 84-7(1929)

**PETER MASUCCI**  
Hydrogen ions and the spinal medulla. **MICHELE MIROLO.** *Boll. soc. ital. biol. sper.* 4, 88-90(1929).—The influence of the H-ion concn. was studied on the isolated spinal medulla of *Bufo vulgaris*, Baglion's central prepn. being used. Pieces of cotton batting (1-2 mm. diam.) soaked in HCl solns. of varying concns. were applied for 30 mins. on the dorsal or ventral intumescence of the spinal medulla. The results indicate that the H ions when acting on the sensor-coördinator elements induce a const. increase of reflex excitability, and with fuming HCl this is manifested in the form of spontaneous tetany of the posterior ends of the prepn. This is followed later, if the concn. of the acid is 1-10%, by central depression and paralysis. When the H ions act on the central motor elements, even in dil. solns., they provoke a torpor of reflexes and a diminution of excitability which leads to a rapid central paralysis.

**PETER MASUCCI**  
The enzymic hydrolysis of acetyl, formyl and benzoyl derivatives of amino acids. **HIDRO KIMURA.** *J. Biochem. (Japan)* 10, 207-23, 225-50(1929).—Histozyne hydrolyzes not only hippuric acid but also benzoyl derivs. of other amino acids. The hydrolysis of various amino acid derivs. was studied by means of glycerol exts. from different organs of rabbits, pig and dog. The kidney and liver of rabbits hydrolyze hippuric acid only slightly or not at all, but do attack most vigorously the acetyl or formyl deriva. of amino acids, which are likewise hydrolyzed by exts. from various other organs. All organs of the pig hydrolyze acetyl and formyl derivs., while liver and kidney also hydrolyze hippuric acid. The pancreas scarcely hydrolyzes hippuric acid, but does

hydrolyze acetyl- or formyl-*dl*-phenylalanine much better than kidney or liver. Acetyl and formyl derivs. are well hydrolyzed by most organs of the dog, while hippuric acid is hydrolyzed only by the kidney. The optimum  $p_H$  is 7.2-6.4; there is little variation for the various acylamino acids. The enzymes that hydrolyze acetyl- and benzoyl-glycine are fairly resistant to acid or alkali, since they are destroyed after 20 hrs. in the ice box only at  $p_H$  1.2 or 12. Heating for 1 hr. at 65-70° considerably reduces their activity while at 75° it is completely lost. The addn of Na acetate or formate does not inhibit the hydrolysis of the acetyl or formyl derivs. while the addn. of amino acids, especially of *dl*- or *l*-leucine, causes inhibition. The leucine, however, has no effect on the hydrolysis of derivs. of leucine, but does affect that of glycine or phenylalanine. The acetylamino acid-splitting enzymes are best adsorbed at  $p_H$  3.4 by  $Al(OH)_3$ , but not by kaolin, and can be leached out with  $(NH_4)_2HPO_4$ . S. MORGULIS

The nature of the co-enzyme. A. P. STRUYK. *Bull. trimestr. assoc. école sup. brasseurie univ. Louvain* 29, 16-22(1929).—See C. A. 21, 2908. A. PAPINEAU-COUTURE

Odor and chemical structure. F. PIRRONI. *Rivista ital. essenze profumi* 11, 2-5(1929).—There are two osmophore groups in odorous compds., the stronger creating the type of the odor, the other the variety. The rest of the mol. has its influence, analogy of the chem. constitution often bringing with it similarity of odor; e. g., fural resembles BzH in odor; furalacrolein resembles cinnamon; and nitrothiophene resembles nitrobenzene. However, there are compds. of similar odor with completely different chem. constitutions; e. g., tertiary trichlorobutyl alc. is similar in odor to bornyl acetate; many compds. have a camphor odor; and the odor of anis, lemon, cinnamon, mint, etc., is found in many very different org. compds. Natural musk and muscone are completely different from the nitroso compds., although the odors are very similar. The entrance of a methyl group in the aromatic series does not modify the fundamental odor. Lengthening of a lateral chain changes the odor; e. g., there is no similarity in the odors of BzH and of  $PhCH_2CHO$  or those of  $PhCH_2OH$  and  $PhCH_2CH_2OH$ . In esters, increasing mol. wt. of the alc. radical causes decreasing odor. Unsatt. bonds in a mol. have a strong influence on the odor; their position is also important. R. SANSONE

The protective action of some substances on protoplasm. V. V. LEPESHKIN. *Am. J. Botany* 16, 207-18(1929).—The protective action of narcotics on the protoplasm of yeast which was affected by poisonous substances was investigated. The narcotics used were ether, chloroform, nitrobenzene and furfurol, and the poisons I,  $CHCl_3$ , and alc. All narcotics used show a protective action on protoplasm if employed in suitable concn. If the concn. is too high the harmful effect of narcotics diminishes their protective action or annihilates it completely so that the favorable action is transformed into a harmful one. The protective effect of the narcotics which possess a high dielec. const. is stronger than that of the narcotics with a low dielec. const. The substances, which penetrate protoplasm comparatively easily but are not accumulated in it, act protectively in 2 ways. They may remove water from protoplasm like other substances producing plasmolysis, and they may dissolve in protoplasm and sep. the mols. of the principal compds. of living matter from each other as do the narcotics. Consequently some protect protoplasm more than do the narcotics. Among the poisonous substances used I dissolves first in living protoplasm, and then it acts on the proteins and lipoids of protoplasm chemically. This chem. action produces a decompn. of the principal compds. of the latter which leads to death. The soln. of I in the living protoplasm of yeast has a brownish color, as compared with the yellow color of a soln. of I in  $H_2O$ . J. J. S.

Studies of heredity by means of enzyme chemistry. I. HANS V. EULER AND HAROLD NILSSON. *Arkiv. Kemi, Mineral. Geol.* 10B, No. 6, 1-6(1929).—The validity of Mendel's law is demonstrated by detns. of the catalase content of the cotyledons of germinated barley. A white variety of barley deficient in chlorophyll was crossed with barley contg. chlorophyll. A segregation resulted in which the proportion of white to green germs was about 1:3. The catalase content of these showed a consistent difference, the greater amt. of catalase being present in the cotyledons contg. chlorophyll. CORNELIA T. SNELL

The course of oxidation reactions. H. WIELAND. *Anales soc. españ. fís. quim.* 27, 181-91(1929).—The principles of biological oxidation are reviewed. The theory of dehydration is developed and its applicability to the understanding of vital reactions is represented by various examples. The biological significance of hydrogen peroxide, and the participation of Fe in intracellular oxidation and the Warburg theory are discussed. E. M. SYMMES

Susceptibility of proline peptides to enzyme hydrolysis. W. GRASSMANN, H. DYCKERHOFF AND O. V. SCHOENNEBECK. *Ber.* 62B, 1307-10(1929); cf. C. A. 22, 1984, 2381.—In continuation of the study of the specific relation between peptidases and

their substrates, prolylglycine and prolylglycylglycine were used. Both were hydrolyzed strongly by a glycerol ext. of intestinal mucosa, fairly strongly by yeast autolyzate and by glycerol ext. of pancreas. They were not acted on by dry preps. of yeast or of intestinal mucosa, by trypsin-kinase or by papain + HCN. J. J. WILLAMAN

## B—METHODS AND APPARATUS

STANLEY R. BENEDICT

**Determination of iodine in blood.** GULBRAND LUNDE, KARL CLOSS AND JOHAN HOLSR. *Norsk mag. Laegevidenskab.* 89, 500-6(1928).—Obtain 5-10 cc. blood with an instrument previously washed with citrate. Immediately syringe the blood into a measuring cylinder contg. 4 times as much 96% alc., and shake well. Then ext. with alc. in a Soxhlet app. during 4 hours. The total inorg. I is now dissolved in alc. Det. I separately in the soln. and in the residue. Both inorg. and org. I were found in all samples except for a few cases where the org. I component, which is insol. in alc., was diminished after I medication by hyperthyreosis. For detn. of total org. I the following method is necessary: Evap. the alc. ext. to dryness on a water bath. To the residue add water and shake with  $\text{CHCl}_3$ . The I is obtained in the form of "lipoid I." To the aq. soln. add  $\text{CHCl}_3$ , and a little dil. nitrite- $\text{H}_2\text{SO}_4$  mixt. or  $\text{H}_2\text{O}_2$ , by which the inorg. I is freed and can be shaken out with  $\text{CHCl}_3$ . But the nitrite- $\text{H}_2\text{SO}_4$  mixt. also removes free I from some org. combinations. In the aq. residue there still exists some org. I, in combinations which are sol. in alc., insol. in  $\text{CHCl}_3$  and undecomposed by nitrite- $\text{H}_2\text{SO}_4$ . Earlier investigators have not observed this last fraction, and have therefore reported for org. I values that were too low. A. DROGSETTI

**Blood fibrinogen determination with the interferometer.** F. KAUFMANN. *Z. ges. expl. Med.* 62, 165-83(1928).—With as little delay as possible remove the blood from a vein by means of a paraffined or a platinum-iridium needle. Place a part of it in a paraffined tube and another part in a tube contg. a small quantity of paraffin. Cover the blood with water-free liquid paraffin. The refractive indices for hirudinized plasma and native plasma are practically identical, so that either may be used. Centrifuge the tubes and use the clear plasma. Remove the fibrin by the use of a glass rod. The difference between the refractive index for hirudinized or native plasma and for the defibrinated plasma is the fibrin, and the value for each may be detd. against water or the hirudinized plasma may be placed in one path of the interferometer and the plasma serum in the other. A table must be constructed for each interferometer. The method can be made easier by using citrated plasma and pptg. the fibrin by heating at 56-57° for 5 mins. K. used isotonic Na citrate, 5 parts plasma to 1 part citrate soln. Recalcification of plasma for pptn. of fibrin gives inconst. results. The addn. of gum solns having the same viscosity as the citrated plasma acts on the Ca citrate complex and results in quant. removal of the fibrin. A bibliography is included. F. L. DUNN

**Estimation of blood sugar.** HORKHEIMER. *Pharm. Ztg.* 74, 546(1929).—After a review of the methods of Kaufmann, Glassmann and Hagedorn-Jensen, the conclusion is reached, based upon comparative expts., that the rapid method of Kaufmann yields only approx. values and should not, therefore, be resorted to in the lab.; and that the microchem. method of Hagedorn-Jensen should be given the preference. W. O. E.

**The estimation of pepsin.** W. SCOTT POLLARD AND ARTHUR L. BLOOMFIELD. *J. Clin. Investigations* 7, 45-55(1929).—A series of test tubes contg. increasing dilns. of pepsin enzyme (pepsin) are treated with a standard 2% soln. of edestin adjusted to  $p_H$  2.0. After incubation at 37° for 1/2 hr., the undigested protein is pptd., centrifuged and its quantity compared with the control tubes similarly treated. A. G.

**A note on "optimal" hydrogen-ion concentrations in colloidal gold in the Lange test.** HUGH NICOL. *J. Soc. Chem. Ind.* 48, 100T(1929); cf. *C. A.* 23, 750.—"In the present state of our knowledge too great precision would be unscientific. The results of the author's work are in agreement with what appears to be the consensus of recent opinion, that colloidal gold intended for use in the Lange test should be neutral, or, preferably, slightly alk. From the point of view of prepn. of the sol it is desirable to have it alk. If it is desired to reduce the alky., that may be effected by addn. of  $(\text{COOH})_2$  without altering the physical condition of the sol." J. A. KENNEDY

**An improved apparatus for measuring quantities of gases and vapors in experiments involving inhalation.** H. BRÜCKNER. *Arch. Hyg.* 101, 16-26(1929). E. R. MAIN

**Determination of the different nitrogenous constituents of urine by fractional precipitation with mercuric chloride.** B. LUSTIG AND B. SPEISER. *Biochem. Z.* 206, 340-59(1929).—The reaction of the urine to be analyzed is adjusted to a  $p_H$  = 5.2 by means of Kolthoff's indicator made up by mixing equal vols. of an alc. 0.2% soln. of

methyl red and 0.1% soln. of methylene blue. The urine is pptd. with  $\text{HgCl}_2$ , and the ppt. and filtrate are worked up separately. The ppt. is extd. successively with warm 0.3%  $\text{AcOH}$ , 0.5%  $\text{HCl}$  and with 1%  $\text{HCl}$  in alc. The filtrate is again fractionated by means of 50%  $\text{Na}$  acetate, and the ppt. thus formed is also extd. with warm 1%  $\text{HCl}$  and with 1%  $\text{HCl}$  in alc. In the filtrate  $\text{NH}_3$ , peptone and allantoin are detd. By analyzing the various fractions for  $\text{N}$ , the concns. of amino acids,  $\text{NH}_3$ , creatinine, pigment, etc., are detd. The method is rather involved, but it is claimed that 98–99% of the total  $\text{N}$  is thus accounted for by this procedure of fractional pptn. and extn. S. MORGULIS

The pigment analysis of urine. VII. Spectrometric determination of urobilin. M. WEISS. *Biochem. Z.* 207, 151–8(1929); cf. *C. A.* 23, 626.—With the aid of a new spectrometer and a comparison tube with a known amt. of ceribilin, the urobilin content of urine, feces and bile is easily detd. S. MORGULIS

The determination of organic acids of urine and of the equivalent bound base in small quantities of urine. FRITZ MAINZER AND ANNA JOFFE. *Biochem. Z.* 207, 167–76(1929); cf. *C. A.* 23, 1672.—The principle of this method is that of Van Slyke and Palmer's but the procedure is different. A sample of 25 cc. of urine is mixed with 0.5 g.  $\text{Ca}(\text{OH})_2$ , well shaken and allowed to stand 30 mins. before filtering. This removes phosphates and carbonates, which would interfere with the titration. The filtrate is dild. with an equal vol. of  $\text{CO}_2$ -free  $\text{H}_2\text{O}$ , and 5 cc. is measured into each of 4 similar test tubes. To each of 2 test tubes is added 0.1 cc. 1% phenolphthalein soln. and both are titrated with 0.25  $N$   $\text{HCl}$  from a microburet to the first disappearance of the red color ( $p_{\text{H}} = 8.0$ ). To each is added 3 drops of 0.1% aq. soln. of the  $\text{K}$  salt of benzenesulfonic acid-azobenzyl-aniline, and the titration with 0.25  $N$   $\text{HCl}$  is continued to  $p_{\text{H}} = 2.7$ . This point is detd. by titrating one sample to  $p_{\text{H}} = 2.6$  and the other to  $p_{\text{H}} = 2.8$ , comparing the colors with 2 samples of corresponding  $p_{\text{H}}$  made up according to MacIllvaine's system of phosphate-citric acid buffers. Two 5-cc. samples are used with the same amt. of indicator. The mean of the 2 titrations gives the amt. of 0.25  $N$   $\text{HCl}$  required for  $p_{\text{H}} = 2.7$ , and a correction of 0.05 cc. is made for the blank. The uncorrected amt. of org. acid in milliequivs. is calcd. as follows: milliequiv. = (titration cc. — 0.05)  $\times$  cc. urine/10, where the titration cc. represent the amt. of 0.25  $N$   $\text{HCl}$  required to titrate from  $p_{\text{H}} = 8.0$  to  $p_{\text{H}} = 2.7$ . To det. the base bound to the org. acid, the total amt. of 0.25  $N$   $\text{HCl}$  used previously is added to the remaining samples of the urine filtrate, and this is titrated with 0.25  $N$   $\text{NaOH}$  back to the original  $p_{\text{H}}$  of the urine. The  $p_{\text{H}}$  of the urine is detd. with the aid of MacIllvaine's  $\text{Na}_2\text{HPO}_4$ -citric acid buffers covering a range of  $p_{\text{H}}$  2.6 to 8.0. Various indicators are prescribed for the different  $p_{\text{H}}$  ranges. Albumin in the urine seriously interferes with the detn. S. MORGULIS

Studies of Van Slyke's method. L. ROSENTHALER. *Biochem. Z.* 207, 298–301 (1929).—Various org. compounds were investigated from the point of view of their reaction with  $\text{HNO}_2$  in the Van Slyke amino acid app. The results are expressed in terms of  $N$ /mol. S. MORGULIS

Determination of levulose in urine. C. I. KRUISHEER. *Biochem. Z.* 207, 441–6 (1929).—The principle of the method is destruction of aldoses by an excess of  $\text{I}_2$  in alk. soln while the levulose remains untouched (99%). After removal of the excess  $\text{I}_2$ , the levulose is then detd. titrimetrically. Ten cc. of urine with no more than 3% total sugar are measured into a 100-cc. volumetric flask, dild. with 30 cc.  $\text{H}_2\text{O}$  and 5 cc. 4  $N$   $\text{NaOH}$  and treated with 16 cc. of an  $\text{I}_2$  soln. (13 g.  $\text{I}_2$  and 15 g.  $\text{KI}$  in 100 cc.), or more, as the case may be, until the mixt. is colored brown by the excessive  $\text{I}_2$ . A few mins. later (5–7 mins.) 3 cc. 4  $N$   $\text{H}_2\text{SO}_4$  is added, and the excess  $\text{I}_2$  removed with 20%  $\text{Na}_2\text{SO}_3 \cdot 7\text{H}_2\text{O}$ , until the soln. is just barely colored. The last traces of  $\text{I}_2$  are removed carefully and exactly with 2%  $\text{Na}_2\text{S}_2\text{O}_3$ , starch being used as indicator. The soln. is now neutralized with 4  $N$   $\text{NaOH}$  to methyl orange, dild. to vol. and the levulose detd. by the usual Fehling procedure. An accuracy of 0.05% is claimed for the method, by means of which dextrose and levulose can be detd. in the same material. It has also been found that heating with  $\text{HCl}$  destroys levulose up to a certain degree, a definite concn. remaining. S. M.

A biological method for the determination of thyroid activity in animals. B. ZAVADOVSKII AND M. NOVIKOVA. *Endokrinologie* 1, 167–73(1928).—The method consists in the implantation of the thyroid from different species into axolotls. A min. dose of 30 mg. and an optimum dose of 50 mg. of thyroid were necessary to induce metamorphosis of a 4–10-g. axolotl into an amblystoma. The relative activities of various thyroids are thus tested. S. MORGULIS

The influence of temperature on the staining of blood smears. GEORG W. OCHS. *Folia Haematol.* 37, 241–57(1929).—Staining depends more on colloidal conditions than on chem. union of dye and cell protoplasm. In general, an increase in temp. increases adsorption, hence intensity of staining. This does not hold with methylene blue

or eosin, probably because the degree of dispersion decreases.  $p_H$  affects the degree of dispersion; at  $p_H$  6.0 the particles are smaller than at  $p_H$  6.8. The bibliography contains 29 titles.

JOHN T. MYERS

**Method of determining a small quantity of morphine in urine and gastric juice.** CHOSAKU WADA. *Keio J. Med.* 8, 1017-34(1928).—The morphine is extd. with  $CHCl_3$ , a definite quantity of 0.01 *N* I soln. is added, the pptd. morphine periodide filtered off and the excess I titrated with 0.005 *N*  $Na_2S_2O_3$ . This titration is compared with a blank titration on the original liquid.

## D—BOTANY

THOMAS G. PHILLIPS

**Chlorophyll from tropical plants and its determination by means of the spectrograph.** R. H. DASTUR AND N. A. BUHARIWALLA. *Ann. Botany* 42, 949-64(1928).—Willstätter's methods of extn. were applied to various local plants of both sun and shade types, for which yields of pure chlorophyll are given. A spectrographic method is described for the detn. of the amt. of chlorophyll from a single leaf. From a study of leaves of different ages, it is concluded that chlorophyll content and water content increase in rather definite ratio to maturity; after maturity the water content decreases more rapidly than does chlorophyll content.

JOSEPH S. CALDWELL

**Chemical studies in the physiology of apples. X. A quantitative study of chemical changes in stored apples.** D. HAYNES AND H. K. ARCHBOLD. *Ann. Botany* 42, 965-1017(1928).—A rather full discussion of the difficulties incurred in the analysis of stored fruits and of the methods employed in the present work precedes the presentation of data. Two lots of Bramley's Seedling apples, one of low and one of high N content, were employed, identical portions being stored at 12° for 174 days and at 1° for 370 days; portions were removed for analysis at intervals of about 3 weeks. At 12°, the apples of low-N content lost larger percentages of water, sucrose, total sugar and alc-insol residue, and a smaller percentage of acid, than the high-N fruits. At 1° the behavior of the 2 lots was similar, but the high-N fruit succumbed to physiol. disease after 252 days. Its storage life was thus only  $\frac{2}{3}$  that of the low-N fruit. Low N and high sucrose are factors favoring long keeping. The N content of the apple is a principal factor in detg. its respiratory rate, and the ratio of loss of total respirable material to N content is closely const. in the 2 lots of fruit for proportional periods of their storage life. Exponential curves of closest fit for dry weight, total sugar, sucrose, acid, cell wall material and total respirable material are plotted for the 2 lots of apples; comparisons show close parallelism of the curves for dry weight and total respirable material in the 2 lots of fruit. In the high-N series, internal breakdown was characterized by reduction of the stored acid to a point too low to maintain the acidity of the protoplasm.

J. S. C.

**Studies on the transport of nitrogenous substances in the cotton plant. I. Preliminary observations on the downward transport of nitrogen in the stem.** E. J. MASEKELL AND T. G. MASON. *Ann. Botany* 43, 206-31(1929).—The material employed was that already employed in studies of carbohydrate transport (cf. *C. A.* 22, 1379, 3903) and included samples taken at 2-hr. intervals over 24 hrs. In the leaf N falls in amt. during the night, rising during the day. In the bark of plants bearing no bolls it increases during the night and early morning, declines at midday and rises again in the afternoon, thus following the changes in the leaf with a lag. In plants bearing bolls it varies very little from day to night. In plants from which a ring of bark had been removed, the diurnal changes of N in leaves and in bark below the ring were like those in normal plants, indicating that nitrates are transported through the wood. In plants which had flaps of bark sepd. from the wood except at the upper end, the N content was that of bark of intact plants, but was significantly lower when the flaps were severed at their upper ends. In plants which had the bark partially removed, the amts. of N in bark and wood below the constriction were reduced but not in proportion to the area removed, i. e., the rate of transport increased with reduction of the cross-section of the transporting tissues. The variation in N content of the wood in response to variations in supply and demand is about twice that in the bark.

JOSEPH S. CALDWELL

**The biological decomposition of pectin.** ARTHUR G. NORMAN. *Ann. Botany* 43, 233-43(1929).—*Bacillus carotovorus*, *B. atrosepticus*, *B. solaniasprus* and *B. subtilis* were grown upon artificial media contg. 1-2% pectin from lemons. The rate of attack was followed by making detns. of furfural and Ca pectate. All 4 organisms secrete a pectin-decomp. enzyme, destroying pectin more rapidly than the degradation products are used up. The rate of action by *B. subtilis* is much below that of the other organisms.

JOSEPH S. CALDWELL

**The transmission of inhibition through dead stretches of stem.** R. SNOW. *Ann. Botany* 43, 261-7(1929).—Seedlings of *Vicia faba* were decapitated at the epicotyl, allowed to develop 2 axillaries of the cotyledons, and one of these was decapitated, the other allowed to grow. The growing shoot inhibited development of lateral buds on the decapitated one, which was removed if the growing shoots were in turn decapitated. Inhibition continued after killing of a zone at the base of the decapitated shoot by heat. Apparently the inhibiting substance was transported downward in the growing shoot, thence upward with the transpiration stream through the dead zone to the buds of the decapitated shoot.

JOSEPH S. CALDWELL

**An investigation of the changes which take place in the chemical composition of pears stored at different temperatures, with special reference to the pectic changes.** A. M. EMMETT. *Ann. Botany* 43, 289-308(1929).—Pears of the variety Conference were stored at 12°, 5°, 4° and 1° in the years 1924-1926. The methods of analysis were those developed by Haynes and co-workers in concurrent studies on apples, pectins being detd. by the method of Carre, and the results are compared throughout with those of these authors with apples. At 12° the fruit ripened in 10-12 days; at 1° there were few indications of ripening after 180 days. The rate of decompn. of pectic substances was very closely paralleled by the rate of ripening. Formation of sol. pectin is the chief factor concerned in softening of fruit, and accounts wholly for the decrease in alc.-insol. material during ripening. Differences in keeping quality appear to be due mainly to differences in the rate of breaking down of pectic compds. Breaking down of pectins occurs more rapidly at 12°, more slowly at 1°, than in any apples thus far examd. This suggests that in low-acid fruits the process is enzymic, while hydrolysis by acids may occur in fruit of higher acidity. The general course of change in chem. compn. in storage in pears is similar to that in apples, the chief difference being that some nonpectic materials are involved in the decompn. of the cell walls in apples but not in pears.

JOSEPH S. CALDWELL

**The interaction of factors in the growth of Lemna. II. Technic for the estimation of dry weight.** M. THET SU AND ERIC ASHBY. *Ann. Botany* 43, 329-32(1929).—An elec. resistance coil is so placed within a vacuum desiccator filled with concd. H<sub>2</sub>SO<sub>4</sub>, and connected with a vacuum pump that material may be dried at 50° at a pressure of 5 mm. of Hg. By employing Pt boats enclosed in light glass phials, and weighing with a Bunge micro-balance, samples as small as 0.5 mg. dry weight may be successfully handled. **III. The interrelationship of duration and intensity of light.** ERIC ASHBY. *Ibid* 333-54. The app. described previously (*C. A.* 22, 3904) was employed in growing 4 cultures of *Lemna minor* under const. conditions of temp., nutrient supply and light intensity. One of the cultures was continuously lighted, a second for 12 hrs., a third for alternating 2-hr. periods and a fourth for 6 hrs. out of 24. Four series were run with lights varying from 350 to 1400 foot candles intensity, all at 25°. With 350 foot candles growth was greatest under continuous light; 12 hr. and 2 hr. alternate treatments showed no significant differences, and indicated unrestricted growth, but there was restriction with the 6-hr. period. With 700 foot candles, growth was much more rapid and again greatest with continuous lighting, the 12 hr. and 2 hr. alternate groups showing close similarity. At 1400 foot candles, growth was restricted and it was evident that optimum light intensity had been exceeded. The plants became yellowish green, with thickened fronds. Possible sources of error involved in the method are discussed.

JOSEPH S. CALDWELL

**Studies on the growth of root hairs in solutions. VIII. Structural and intracellular features of collards in calcium nitrate.** CLIFFORD H. FARR. *Bull. Torrey Botan. Club* 55, 529-53(1928).—An earlier paper reported upon structural responses of collard roots and root hairs to CaCl<sub>2</sub> (cf. *C. A.* 22, 1793, 3904). This reports the responses observed in Ca(NO<sub>3</sub>)<sub>2</sub>. In neutral or acid solns. of high salt concn. the aquatic root hairs are equidistant in spacing; in alk. solns. or in low salt concns. they occur in clusters. They show a much smaller range of types than do the amphibious hairs. In both aquatic and amphibious hairs the particular type developed is correlated with the concn. and the p<sub>H</sub> of the Ca(NO<sub>3</sub>)<sub>2</sub> soln. Observations of nuclear behavior in growing hairs indicate that the nucleus tends to move toward the region of most rapid growth but that its presence in such regions ultimately retards growth by interfering with lines of flow of the cytoplasm.

JOSEPH S. CALDWELL

**The absorption of carbon dioxide by the roots and its utilization in the photosynthesis of chlorophyll.** M. BERGAMASCHI. *Atti accad. Lincei* [6], 9, 238-42(1929).—Plants were transplanted after removing all leaves, and planted in soil, the upper part of the plant being in a CO<sub>2</sub>-free atm., while water rich in CO<sub>2</sub> was fed to the roots. The plants grew other leaves, and CO<sub>2</sub> detns. indicated that CO<sub>2</sub> was absorbed through the

roots. Some authors have considered that the leaves alone were concerned in the "breathing" of  $\text{CO}_2$ , but this paper indicates that the roots are effective in absorbing sufficient  $\text{CO}_2$ . A. W. CONTIERI

The behavior of "anthocyanins" at varying hydrogen-ion concentrations. B. H. BUXTON AND F. V. DARBISHIRE. *J. Genetics* 21, 71-80 (1929).—According to the reaction of colored flowers in media of varying H-ion concns., their anthocyanins can be differentiated into 2 main groups, the blue and red. The anthocyanin of the former group is an ultramarine blue at  $pH$  7; that of the latter is a vermillion red at  $pH$  3. The effect of yellow flavones upon the tints produced is considered. Tables and a colored plate are appended. FREDERICK G. GERMUTH

The initiation and acceleration of protoplasmic streaming by means of optically active amino acids. HANS FITTING. *Jahrb. wiss. Botan.* 70, 1-24 (1929).—Protoplasmic streaming was induced or accelerated in the cells of *Vallisneria* plants when the latter were placed in solns. of optically active amino acids. Similar responses, although to a lesser degree, were obtained with certain non-optically active forms of the same acids. The slightly pos. action of the non-optically active acids was regarded as being due to the presence of small quantities of the optically active forms as impurities in the synthetic acid salts. A. E. HITCHCOCK

The influence of moist habitats on the sugar content of plants. V. S. IL'IN. *Planta, Abt. E., Z. wiss. Biol.* 7, 59-71 (1929).—The same species of plants growing in wet and dry habitats had different amts. of sugar, a high sugar content being correlated with a dry habitat. Leaves of *Ficus carica*, *Hedera helix* and *Quercus ilex* showed the max. differences in sugar content (4.8 to 7.7%) under external conditions of max. and min. moisture. Percentage values were based on 100 cc. of expressed juice. A. E. HITCHCOCK

Nitrogen exchange in green plants. HORST ENGEL. *Planta, Abt. E., Z. wiss. Biol.* 7, 133-63 (1929).—When the N supply was cut off from *Callisia*, *Tradescantia* and corn plants, analyses showed a decrease in protein and amide N, and an increase in amino N. The N needs of young leaves were supplied in the form of amino N from protein reserves in old leaves. As a result of this protein decompn., the old leaves yellowed and died prematurely. Similarly, the growing regions of roots received the necessary sol. N from older portions of the root. The suggested course of decompn. is as follows: protein N  $\rightarrow$  amino acids  $\rightarrow$  asparagine  $\rightarrow$   $\text{NH}_3$   $\rightarrow$  inorg. N. A. E. HITCHCOCK

Nitrogen metabolism in underground storage organs. R. GRÜNTUCH. *Planta, Abt. E., Z. wiss. Biol.* 7, 388-420 (1929).—N metabolism was followed in the underground storage organs of *Solanum tuberosum*, *Helianthus tuberosus*, *Dahlia variabilis*, *Asparagus officinalis* and several other plants under different conditions of growth. Total N in these organs varied not only in different plants, but also in the same plant at different stages of development. In spite of this variation the ratio (protein N:sol. N) remained nearly const. On the basis of these results, the physiol. function of vegetative storage organs still remains obscure. A. E. HITCHCOCK

The fixation of atmospheric nitrogen by *Phoma radialis callunae*, including a new method for investigating nitrogen fixation in microorganisms. W. NEILSON JONES AND M. LLEWELLYN SMITH. *Brit. J. Exptl. Biol.* 6, 167-89 (1928).—Chem. analyses of seeds of *Calluna vulgaris* and of seedlings grown on a N-free medium show this plant can use sufficient N from the air to prevent nitrogen starvation. A new app. for the study of N fixation by microorganisms is described. The mycorrhizal fungus of *C. vulgaris* has been grown in pure culture on a N-free medium with and without a supply of mol. N. The amounts of glucose used and N present at the end of an expt. were greater when mol. N was available. C. M. McCAY

The imbibing power of various varieties of rye and wheat. FRANZ HUEBER. *Fortschr. Landw.* 4, 97-100 (1929).—The osmotic pressure of the seedlings of the varieties of wheat tested varied from 23.45 to 34.5 atm.; rye seedlings varied from 27.5 to 34.5 atm. Varieties adapted to heavy soils and those adapted to dry conditions had high osmotic values. LAWRENCE P. MILLER

Investigations on the potash and phosphorus intake of grains in the seedling stage. TH. SCHRADER. *Fortschr. Landw.* 4, 230-3 (1929).—Studies with varieties of rye, wheat, barley and oats, by the method of Neubauer (*C. A.* 18, 877), led to the following conclusions: In nutrient content and intake the varieties show characteristic differences. These differences are brought out in vegetative development as well as by chem. analyses. Varieties that grow rapidly take up the available nutrients in a shorter time than more slowly growing varieties. Potash is taken up more quickly than P. L. P. M.

Transformation of acetic acid into pyruvic and fumaric acids by *Mucor stolonifer* and a method for the separation and determination of these acids. VL. S. BUTKEVICH

AND M. V. FEDOROV. *Biochem. Z.* 207, 302-18(1929).—In expts. where pyruvic, malic, lactic or tartaric acids were acted upon by *Mucor stolonifer* in the presence of  $\text{CaCO}_3$  there was no evidence of a formation of fumaric acid. On the contrary, in expts. where glycerol was used much fumaric acid appeared. Ehrlich's failure to find fumaric acid in cultures contg. glycerol is shown to be due to the fact that he did not use any  $\text{CaCO}_3$ . When the mold was acting on AcOH in the presence of  $\text{CaCO}_3$ , both pyruvic and fumaric acids appeared in large quantities, amounting to 15-30% of the acetic acid consumed. The results are different from those obtained with sugar in that the pyruvic acid is greatly in excess, making up 80-90% of the total amt. of ether-sol. acid produced, whereas in expts. with sugar the pyruvic acid rarely exceeds 10%. These exptl. results support Thunberg's and Wieland's dehydrogenation theory. The appearance of pyruvic acid in various fermentation processes is thought to be possibly due to the formation of AcOH. If sugar is added to the AcOH acted upon by the mold, the process of acid formation is accelerated and the proportion of the 2 acids is shifted in favor of the fumaric acid. This suggests the possibility that the transformation of sugar to fumaric acid goes through a pyruvic and acetic acid stage, but this idea needs further exptl. corroboration. Pyruvic acid can be sepd. from a mixt. with fumaric acid by means of  $\text{KMnO}_4$ , the titration with  $\text{KMnO}_4$  also serving for the detn. of fumaric acid. The same is true, of course, for mixts. of fumaric acid with other substances which do not react with  $\text{KMnO}_4$ .

S. MORGULIS

The ammonia nutrition of higher plants. D. N. PRYANISHNIKOV. *Biochem. Z.* 207, 341-9(1929).—In a neutral medium  $\text{NH}_3$  gives better results while in an acid reaction nitrate is the better source of N for plants. Not only by a change in H-ion concn., but also of other cations in the nutritive medium, the nutrition of the plant can be so altered that its optimum development will result either from  $\text{NH}_3$  or from  $\text{NO}_3$  nourishment. The carbohydrate content plays the most important role as the inner condition, and the greater this is the larger is the amt. of  $\text{NH}_3$  tolerated by the plant which quickly changes this to amide in the production of asparagine or glutamine. Not only excessive nitrogenous nourishment, but everything interfering with the synthesis of org. matter (too much acid in medium, anesthetics) can produce ammonia poisoning in plants.

S. MORGULIS

Report on (the determination of) plant (constituents). O. B. WINTER. *J. Assoc. Official Agr. Chem.* 12, 193-4(1929).—A microchem. method has been developed by which Fe and Al can be pptd. as phosphates, the Fe and Al sepd., and each detd. colorimetrically. In the hands of 3 analysts the method gave results which fell within a range of approx. 5% error. The details of the method will be published later. A. P.-C.

Report on (the determination of) total chlorine in plants. DORIS H. TILDEN. *J. Assoc. Official Agr. Chem.* 12, 195-200(1929); cf. *C. A.* 22, 2768.—The results of collaborative detns. of Cl in plant material based on methods involving incineration with  $\text{Na}_2\text{CO}_3$  as a fixative for Cl indicated that the modified gravimetric (pptg. in the cold with a slight excess of  $\text{AgNO}_3$ , shaking till the ppt. becomes granular, letting settle and washing by decantation before transferring to the Gooch crucible, keeping the pptn. flask covered with a black cloth as far as possible during the manipulations), Gay-Lussac and Volhard methods are equally reliable and accurate. Results showed wide variations with the same sample soln., possibly because of the presence of too large an amt of org. solids. Methods for the detn. of Cl in plant material involving wet ashing or the "open Carius method" have so far proved unsatisfactory on account of the difficulty of removing all the org. matter prior to making the back titration with KCNS.

A. PAPINEAU-COUTURE

The influx of nutritive salts from the outflow and inflow water relative to the sprout and root mass and the leaf structure. I. II. JOSEF KISSER. *Anz. Akad., wiss. Wien* 64, 29-30(1927).—The plant *Triticum vulgare* was placed in distd.  $\text{H}_2\text{O}$  in solns. of the c. p. nutrient salts. The anions were const. Thus the attained results occurred only under the influence of the cations, and the influence of osmosis was eliminated by the use of dil. solns. With 100 g. masses the transpiration decreased with Mg, K and Na nutrient. Considering the  $\text{H}_2\text{O}$  adsorption, the K adsorption was greatest and less for Ca, Mg and Na. By an increase in the concn. of salt the rate of adsorption was decreased. The  $\text{H}_2\text{O}$  economy for Ca nutrient appeared especially unfavorable; the K nutrient under other conditions gave different results (when there was little root system and no root hairs). With an increased concn. of K nutrient a rapid rise was noted in sprout and root mass but with Ca nutrient there was a decrease. Each nutrient salt produced a change in the anatomy of the leaves. The Ca nutrient produced fewer hairs and stomata than distd.  $\text{H}_2\text{O}$ , the Mg nutrient more. In the K nutrient the production of hair and stomata was decreased but not in the proportion as noted with Ca

nutrient. Variations in the structure of the mesophyll and in the thickness of the bottom epidermis were noted for each salt. M. H. SOULE

**Effects of storage on alcoholic extracts of plant tissues. Amino acid changes.** JAMES E. WEBSTER. *Plant Physiol.* 4, 141-4(1929).—The effect of storage on the content in  $\alpha$ -amino acids of alc. exts. of spinach was detd. after the addn. of excess of  $\text{CaCO}_3$ . Five conditions were examd., viz., (A) spinach ext., stored in Jan., in warmth and light; (B) spinach ext. + nitrate ( $\text{KNO}_3$ ), stored as (A); (C) spinach ext., stored in Aug., in darkness; (D) spinach ext. + asparagine, stored as (C); and (E) young alfalfa ext., stored in Sept., in warmth and light. A marked decrease in amino N occurred under all 5 conditions. The mechanism of deamination is discussed. W. T.

**X-ray photography of mineral accumulations in plants.** C. L. CRUTCHFIELD. *Plant Physiol.* 4, 145-54(1929).—X-ray photography exceeds in sensitivity the microchem. methods of detecting accumulations of Al and Fe in the nodes of corn stalks (C 17, 2301). The possibilities of this method in the investigation of problems connected with translocation of salts in plants are pointed out. Six x-ray photographs showing the behavior of Ca, Fe, K and Na are reproduced. Addnl. work is in progress. W. T.

**Schloesing's experiments on the relation of transpiration to the translocation of minerals.** W. E. LOOMIS. *Plant Physiol.* 4, 158-60(1929).—The classic expt of Schloesing has been given an unjustified importance in establishing the dependence of mineral movement in the plant upon transpiration. The data are better interpreted, as showing the effects of increased  $\text{CO}_2$  rather than of decreased transpiration. W. T.

The chlorate method for the determination of nitrate N, total N and other elements in plant tissues (EMMERT) 15. Studies of certain phases of the interrelationship between soil and plant. I. Availability of mineral plant nutrients in relation to the degree of dispersion (THOMAS) 15.

## E—NUTRITION

PHILIP B. HAWK

**Growth-promoting vitamin A. I. Vitamin-A-choleic acid.** T. SHIMIZU AND T. HATAKEYAMA. *Z. physiol. Chem.* 182, 57-71(1929).—The vitamin-A prepn. was obtained from the yolks of boiled eggs by  $\text{Et}_2\text{O}$  extn., sapon. of the ext. with alc. KOH, pptn. of fatty acids by alc.  $\text{CaCl}_2$ , removal of excess Ca by  $\text{CO}_2$ , evapn. of the  $\text{EtOH}$  extn. of the residue with  $\text{Et}_2\text{O}$ , shaking the ext. successively with HCl,  $\text{Na}_2\text{CO}_3$  and  $\text{H}_2\text{O}$ , drying with  $\text{Na}_2\text{SO}_4$  and evapg. After addn. of a min. quantity of MeOH and cooling with ice, the cholesterol sepd. and was filtered off. Evapn. of the filtrate then left a dark orange-red residue. Most of these operations were carried out in an atm. of N or  $\text{CO}_2$ . For the isolation of vitamin A, Wieland's choleic acid principle was applied. The vitamin residue obtained as above was dissolved in 100 parts of abs.  $\text{EtOH}$ , a few drops of  $\text{H}_2\text{O}$  added and 4.5 parts of desoxycholic acid. The mixt. was evapd to dryness, dissolved in warm abs.  $\text{EtOH}$  and  $\text{H}_2\text{O}$  added to incipient fluorescence. On standing overnight yellow crystals of the *vitamincholeic acid* sepd., m.  $179^\circ$ ,  $[\alpha]_D^{25} 45^\circ$ . The yellow color disappears when the substance is dissolved in alkali and reappears when the substance is again pptd. out by HCl. The name *gallosterol* is proposed for the complex. The difficult soly. of the substance in abs.  $\text{Et}_2\text{O}$  or abs.  $\text{CHCl}_3$  makes it easy to sep. from free vitamin A and cholesterol. Its Na, K and Ca salts are sol. in  $\text{H}_2\text{O}$ . It contains 16.8% vitamin A and corresponds to the formula  $(\text{C}_{27}\text{H}_{46}\text{O}_4)_x \cdot \text{C}_{27}\text{H}_{44}\text{O}_2 \cdot \text{H}_2\text{O}$ . In contrast to the free vitamin it is quite stable to light and air. When *gallosterol* is boiled 40 mins. with xylene in a  $\text{CO}_2$  atm., the desoxycholic acid unites with xylene and ppts. out as the difficultly sol. xylenecholeic acid, while the vitamin A is liberated and remains in soln. Another method of sepn. is by distn. in high vacuum; with a bath temp. of  $200-50^\circ$  the vitamin distils over and by treatment of the distillate with abs. MeOH it may be obtained in crystals m.  $187^\circ$ . This substance, for which the name *vitosterol* is proposed, gives the Liebermann reaction, at first orange-red, then violet-red and finally blood-red; a distinction from cholesterol and sitosterol is that the  $\text{CHCl}_3$  soln. remains colorless. Analysis corresponds to the formula  $\text{C}_{27}\text{H}_{44}\text{O}_2$ . Addn. of I and catalytic hydrogenation both indicate the presence of 2 double linkages. The hydrogenation product was a yellow oil. Feeding expts. were performed with young mice. Addn. of *gallosterol* to a vitamin A-free diet gave normal growth. Desoxycholic acid had no toxic action when given with a complete ration, but became toxic when the ration was deficient in vitamin A. A daily dose of 0.23 mg. *gallosterol* to avitaminous mice was not sufficient to check the loss in wt. or the symptoms of avitaminosis, but 0.3-0.42 mg. per day brought about an increase in wt. and the disappearance of avitaminosis. A. W. DOX

**Recent advances in our knowledge of vitamins.** R. F. HUNWICKE. *Quart. J. Pharm.* 1, 581-9(1928); cf. *C. A.* 22, 2592.—A review. W. O. E.

**Tissue calcification under the influence of vitamin D.** C. R. H. RABL. *Deut. med. Wochschr.* 55, 63-4(1929).—The injection of  $\text{CaCO}_3$  into white mice, accompanied by an overfeeding of vitamin D, resulted in pathological calcification of the viscera, particularly the kidneys. ARTHUR GROLLMAN

**Vitamins as factors in health and in food values. II.** HENRY C. SHERMAN, D. B. JONES, T. P. B. JONES, E. L. FISK AND C.-E. A. WINSLOW. *Am. J. Pub. Health* 19, 482-7(1929); cf. *C. A.* 22, 2399.—Progress rept. with review of the literature. J. A. KENNEDY

**Relationship between vitamin (biosterol and oryzanin) and immune body.** TOKUJI SAITO. *Sei-i-Kwai Med. J.* 47, No. 12, 81-8(1929). (In English, 4.)—No relationship was found. W. D. LANGLEY

**Hemoglobin maintenance upon synthetic diets.** DAVID L. DRABKIN AND C. STANLEY WAGGONER. *Science* 69, 480(1929).—Dogs fed on the Karr-Cowgill diet maintained hemoglobin at a const. normal level. The casein and Vitavose in this diet furnished only  $\frac{1}{4}$  as much Cu per kg. of body wt. as Hart fed to rats on whole milk diets. Addn. of  $\text{CuSO}_4$  to the diet had no effect on the hemoglobin maintenance of the dogs or on their speed of recovery after bleeding. A Cu-free synthetic diet was devised, egg albumin being used instead of casein and yeast instead of Vitavose. The growth, general appearance and hemoglobin maintenance were normal in rats on this Cu-free diet, as well as in rats fed this diet with Cu salts added. Rats that had been rendered anemic by a whole milk diet were cured by the synthetic Cu-free diet.

AMY LE VESCONTE  
**The influence of feeding on certain acids in the feces of infants. I.** A comparison of the effects of breast milk and modified cow milk on the excretion of volatile acids. JESSE R. GERSTLEY, CHI CHE WANG, RUTH E. BOYDEN AND AGNES A. WOOD. *Am. J. Diseases Children* 35, 580-9(1928).—The total titratable acidity and volatile acid content of the feces remain const. during maintenance upon breast milk. Wide variations become apparent upon shifting the diet to mixts. of cow milk. It is suggested that an unstable condition in the intestinal tract may be assoc. with the digestion of the latter food. E. R. MAIN

**The respiratory metabolism in infancy and in childhood. VIII.** The respiratory exchange in marasmus: basal metabolism. SAMUEL Z. LEVINE, JAMES R. WILSON AND GERTRUDE GOTTSCHALL. *Am. J. Diseases Children* 35, 615-29(1928); cf. *C. A.* 22, 4158.—The basal metabolic rate of undernourished infants is approx. 80 cal. per kg. per 24 hrs.; that of well-nourished infants is about 30% lower. The high rate observed for the undernourished infants does not appear to indicate the existence of an abnormal respiratory metabolism, but may, rather, be the result of a marked decrease in the reserves of metabolically inert tissue, which constitute about 30% of the body weight in well-nourished infants. E. R. MAIN

**Vitamin requirements of the nursing young. II.** The production of beriberi in the nursing young (*Mus norvegicus albinus*) associated with hemorrhages. BARNETT SURE AND S. J. SCHILLING. *Am. J. Diseases Children* 35, 811-22(1928).—Diets, which contain sufficient quantities of vitamin B to protect adult white mice, may not prevent the occurrence of beriberi or polyneuritis in their nursing young. It is suggested that deficiencies in the vitamin B content of the diets of infants may be more prevalent in this country than hitherto recognized. E. R. MAIN

**The influence of overheating on the alimentary value of cereals.** AGOSTINO CASTELLI. *Biochim. terap. sper.* 15, 425-40(1928).—In order to get accurate and comparable results, it is absolutely necessary that the heat be uniform and penetrate through the entire mass. The overheated grains, either by satd. steam at ordinary pressure for 3 hrs. or by satd. steam at  $1\frac{1}{2}$ - $3\frac{1}{2}$  atm. pressure for  $1-2\frac{1}{2}$  hrs., undergo changes which modify their nutritive value and produce in pigeons all the symptoms of exptl. beriberi. The onset of the disease is more rapid and grave when the pigeons are fed with grain autoclaved at  $1\frac{1}{2}$  atm. for  $2\frac{1}{2}$  hrs. The syndrome is similar to that shown by pigeons fed with polished rice. If at the onset of the beriberi symptoms, autoclaved grain is substituted for the polished rice, the birds show signs of a better appetite and a slight improvement manifested at times by a transitory arrest of the polyneuritic symptoms and an increase in body wt. Later, the animals succumb to the characteristic syndrome. If polished rice is substituted for autoclaved grain, the disease becomes aggravated, the animals lose wt. and their period of survival is shortened. These tests indicate that the nutritive deficiency of grain heated at  $127-128^\circ$  for  $2\frac{1}{2}$  hrs. is no greater than that observed by feeding polished rice. The syndromes caused

by both are identical. Therefore, the term "devitaminized food" applies to both decorticated grain and grain overheated within the limits necessary to cook and sterilize it.

PETER MASUCCI

**Nitrogen metabolism. III. The relation between "traceable" nitrogen and "non-traceable" nitrogen during alimentation with various proteins.** UGO LOMBROSO AND SALVATORE DI FRISCO. *Boll. soc. ital. biol. sper.* 3, 795-8(1928); cf. C. A. 22, 3911.—By "traceable" N is meant that N which administered to an animal can be accounted for by the N in the urine and feces and by the N utilized by the organism for building up its tissues; "non-traceable" N is that quantity of N not accounted for either in the excretions or in the tissues. A large part of the N unaccounted for occurs during the fasting of animals. This suggested the inquiry whether this loss is related to the chem. structure of the protein destroyed in the tissues during the fast or depends upon general conditions peculiar to the organism. On administering to albino rats a diet with casein as a base, there is at first an elimination of N in the urine and feces which corresponds to that of the diet. When there is a deficit there is also simultaneously an increase in wt. to account for this deficit. If casein is administered for longer periods, the amt. of N in the urine and feces may be about 35% lower than the N in the diet administered, with no corresponding increase of N in the organism. Somewhat similar results were obtained by feeding the rats bread (gluten plus cooked starch), ovalbumin and meat. The results indicate that the phenomenon cannot be attributed to any particular chem. structure of the protein mol., but is due to factors still unknown.

PETER MASUCCI

**Growth-producing amino acids and the milk feeding of the baby.** CESARE COCCHI. *Boll. soc. ital. biol. sper.* 4, 55-8(1929).—Cow milk was modified by removing  $\frac{1}{2}$  the casein from it and adding to it 6-8 g. per l. of lactalbumin. Babies were nourished with this for several months. The results indicated that milk poor in casein but rich in lactalbumin produces regular growth; there is a profound change in the intestinal flora which is similar in character to that observed in the breast-fed baby; more protein N is utilized than with cow milk; the fecal N is always higher in the baby fed with cow milk. It is not sufficient, therefore, to satisfy merely the min. protein needs but it is also necessary to take into account the min. lactalbumin requirements. P. M.

**Further observations on albino rats fed with egg albumin.** ANTONIO GALAMINI. *Boll. soc. ital. biol. sper.* 4, 91-5(1929).—A male rat fed exclusively on egg albumin survived 151 days. At death its wt. had decreased 42.2% from its original wt. In general, rats fed exclusively on a high protein diet showed functional and anatomical changes of the kidneys. The addn. of starch or butter to egg albumin decreased the amt. of N excreted and caused the green pigment from the urine to disappear. P. M.

**Further investigations on the influence of the feeding of iodine to pregnant sows on the weight of the litter and the development of the young pigs.** ISTVÁN WEISER AND A. ZAITSCHEK. *Fortschr. Landw.* 4, 229-30(1929).—Although conditions were such that the controls made very good growth, the addn. of small amts. of I to the diet resulted in significant increases.

LAWRENCE P. MILLER

**The demonstration of vitamin A.** H. STREUDEL. *Biochem. Z.* 207, 437-40(1929).—Exptl. evidence is given to show that substances which fail to produce the  $\text{SbCl}_3$  blue reaction nevertheless prove themselves in feeding as contg. vitamin A. This fact does not deprive the color reaction of Price and Carr of its value, but neg. results should not be taken to prove an absence of vitamin A unless this is confirmed by feeding expts.

S. MORGULIS

**The vitamin content of various grasses.** ARTHUR SCHEUNERT. *Biochem. Z.* 207, 447-57(1929).—Various pasture grasses were investigated from the point of view of their contents of vitamins A and B. The results substantiate the view that the grasses have a high vitamin A content, 0.5 g. sufficing to insure optimum growth in rats. The vitamin B content is decidedly lower and as much as 4 g. was required to secure only av. growth. The differences in vitamin content of the various grasses were slight.

S. MORGULIS

**The effect of feeding polished rice on the heat reaction of rats.** MAX REISS AND STEFAN PERÉNY. *Endokrinologie* 1, 411-8(1928).—Feeding decorticated rice has an influence on the heat phenomena manifested in the uterus and vagina of the rat, B-avitaminosis producing continuous rut in the normal rat. This does not depend upon the ovary as it occurs also in ovariectomized animals.

S. MORGULIS

**Non-consumption of vitamin B by growing chicken sarcoma.** WARO NAKAHARA AND EIICHI SOMEKAWA. *Sci. Papers Inst. Phys.-Chem. Research (Tokyo)* 10, 211-20(1929).—Livers were obtained from a sarcoma-bearing group of chickens and from an uninoculated group, all fed on a diet lacking vitamin B. The dried liver was fed to

rats losing wt. on a vitamin-B-deficient diet in amts. varying from 0.25 to 1 g. per rat per day. The same gain in wt. for those rats receiving liver from tumor-bearing chickens as in those rats receiving liver from non-tumor-bearing chickens indicates that the liver from each group of chickens is equally active in vitamin B content. Vitamin B may not be necessary for the growth of chicken tumor. N. M. NAYLOR

**Toxicity of aluminum compounds in the diet.** E. V. MCCOLLUM, O. S. RASK AND J. ERNESTINE BECKER. *Bull. soc. hyg. aliment.* 17, 65-73(1929); cf. Schaeffer, *et al.*, C. A. 22, 3686.—A criticism of the work of Schaeffer, *et al.*, not intended as a defense of alum baking powders but showing that the work of Schaeffer is not in agreement with the most recent work of American investigators. The latter have shown that under conditions approximating those of normal diet Al is not appreciably absorbed by the digestive tract, and that the presence in food of the quantities of Al salts resulting from the normal use of alum baking powders is without any great physiol. significance. Cf. following abstract. A. PAPINEAU-COUTURE

**The physiological action of alum baking powders.** G. SCHAEFFER, G. FONTÈS, E. LE BRETON, CH. OBERLING AND L. THIVOLLE. *Bull. soc. hyg. aliment.* 17, 74-87 (1929); cf. preceding abstr.—A reply to McCollum, *et al.* A. PAPINEAU-COUTURE

**Study of the antirachitic action of irradiated substances: irradiated ergosterol.** JEAN HUGUENIN. *M. D. Thesis, Paris*, 1928, 90 pp. A. PAPINEAU-COUTURE

**The effect of ultra-violet rays in rickets with studies on the lime-depositing capacity of the light.** CARL SONNE. *Arch. Phys. Therapy, X-Ray, Radium* 10, 139-49(1929).—Rats kept on rachitogenic food were prevented by ultra-violet radiation from developing rickets. Certain lines of the ultra-violet spectrum were found to be much more effective than others. Animals which had been irradiated had a higher percentage of lime in their bones than those which had not. E. H. QUIMBY

**Preliminary study of a common Porto Rican diet.** DONALD H. COOK, TRINITA RIVERA AND LUIS TORRES DÍAZ. *Porto Rico Rev. Pub. Health and Trop. Med.* 4, 253-5 (1928); cf. C. A. 22, 2397.—Rice and red kidney beans form a large part of the Porto Rican diet. A mixt. of these 2 foodstuffs proved to be inadequate for the normal growth of young rats, which after 8 weeks had gained 46 g., while the wt. of young rats kept on a complete standard diet had increased by 101 g. G. SCHWOCH

**Carotin and vitamin A.** THOMAS MOORE. *Lancet* 1929, I, 499-500.—The physical properties or selective absorption of carotin and "biosterin," a cod-liver concentrate, are entirely different and therefore preclude their identity, in spite of the fact that the minimal physiological (rat) dose of each is the same. The significance and explanations of these facts are discussed. F. B. SEIBERT

**Irradiated ergosterol.** E. H. VOLWILER. *Clin. Med.* 36, 28-31(1929).—A review. M. H. SOULE

**Germinating power, nutritive value and vitamin B content of rice kernels kept in contact with carbon dioxide and with air for 4 years.** MANTARŌ KONDŌ, SHŪZŌ MATSU-SHIMA AND TAMOTSU OKAMURA. *Proc. Imp. Acad.* (Tokyo) 5, 159-60(1929).—No changes were observed after 4 years. C. J. WEST

**Vitamins and calcium in hemodystrophies.** A. BARSOTELLI. *Arch. med. cirug. yespec.* 29, 624 (1928); *J. Am. Med. Assoc.* 92, 186.—In hemophilia and hemorrhagic purpura blood Ca increases while K decreases, but the changes are not in proportion. In the osmotic balance of the plasma quant. changes occur in the Mg and Na. R. C. W.

**The action of different pharmaceuticals on the blood pressure of the pigeon during avitaminosis.** TSUNEMICHI HAYAMA. *Imp. Univ., Kyoto. Folia pharmacol. japon.* 7, 15-6(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 47, 347.—During avitaminosis produced by feeding polished rice, the blood pressure is below normal. In this condition adrenaline acts more slowly and digitalein practically the same as in the normal animal. Acetylcholine and oryzanin produce only a slight increase or none at all. The same results follow the use of these 4 drugs during fasting. R. C. WILLSON

**Vitamin-A deficiency in Newfoundland.** W. R. AYRKROYD. *Irish J. Med. Sci.* 1928, 161-5.—The diet of the av. Newfoundlander is deficient in vitamins. The functional hemeralopia seen among them—it is not directly associated with beriberi or scurvy—is rapidly cured by foods rich in vitamin A. R. C. WILLSON

**The effect of liver on the blood-sugar level.** HARRY BLOTNER AND WILLIAM P. MURPHY. *J. Am. Med. Assoc.* 92, 1332-6(1929).—The liver fractions which are effective in the treatment of pernicious anemia have no effect on the blood sugar, while others which are ineffective in pernicious anemia have effects similar to that of liver. Diabetic patients on liver therapy for 1-12 months showed constantly lower blood-sugar levels than before liver therapy. R. C. WILLSON

LUSK, G.: *The Elements of the Science of Nutrition*. 4th ed., revised and enlarged. 844 pp. Philadelphia and London: W. B. Saunders Co.

## F—PHYSIOLOGY

F. K. MARSHALL, JR.

**The role of hemoglobin in the blood.** A. BAIRD HASTINGS. *Colloid Symposium Monograph* 6, 139-54(1928).—The physiologically important properties of hemoglobin are: (1) it reacts with O in such wise that, in the environment provided by the organism, it takes up O from the lungs and delivers it to the tissues with max. efficiency; (2) it provides the blood with 90% of its capacity to buffer acids by virtue of its constituent weak acid groups and its unique capacity to increase its acidity upon oxygenation; (3) it controls, in large measure, the distribution of diffusible ions between the serum and cells.

JEROME ALEXANDER

**The autolysis of skin.** MARIO MONACELLI. *Arch. Dermatol. u. Syphilis* 157, 31-44(1929).—Histochem. technic demonstrated the appearance of granules in human epidermis during the course of autolysis. By reason of their staining reactions they are believed to be composed of phospholipins derived from a decompn. of preëxisting lipoproteins.

B. C. BRUNSTETTER

**The amount of hormone in the pancreas of several species of animals.** SÔSHIKO TAKEUCHI. *Tohoku J. Exptl. Med.* 12, 62-74(1928).—Exts. of 25 g. portions of fresh pancreas were prepd. by (1) a  $H_2SO_4$ -alc. method or (2) a picric acid-acetone method. These exts. were assayed by the Toronto method except that rabbits of 1-2 kg. body wt. were used, and the dosages were reduced to a 1 kg. body wt. basis. The av. results expressed in rabbit units per 1 kg. pancreas and obtained by method (2) were: dog 2619, horse 1432, hog 1263, ox 916, man 843 and cat 683.

B. C. BRUNSTETTER

**The peroxidase reaction. XXIII. Development of the leucocyte peroxidase in fetal life and the early stages of infancy.** KOJI TOKUË. *Tohoku J. Exptl. Med.* 12, 281-94(1929).—In human embryos and very young rabbits the peroxidase reaction (which runs parallel to the oxidase reaction) becomes progressively stronger.

B. C. BRUNSTETTER

**The mechanism of lymph formation.** G. QUAGLIARIELLO. *Atti accad. Lincei* [6], 9, 243-9(1929).—Of the 2 theories of lymph formation, the physicochem. and the secretory, Q. favors the former. There are 2 arguments against this theory: that the Cl content of the lymph is higher than that in the plasma, and that the cond. of lymph is higher than in the plasma. Q. states that the lymph being formed by diffusion through semi-permeable membranes would naturally show greater concn. of electrolytes which diffuse more readily. As to the argument that the elements are not in chem. equil., it is pointed out that the lymph contains not only products derived from the plasma, but also those derived from the tissues, and in addn. the tissues absorb various compds. selectively, so that one should not expect a strict chem. equil. The membranes as well as the diffusing substances are in a continual state of change. A. W. CONTIERI

**The heavy metals of the human liver and their spectrographic detection.** HILDE TURNWALD AND FELIX HAUROWITZ. *Z. physiol. Chem.* 181, 176-81(1929).—The ash of normal human liver was dissolved in 10% HCl, placed between C electrodes and the arc spectrum photographed in the ultra-violet. In addn. to numerous Fe lines there were distinct lines of Cu, Zn and Mn. The lines of P, Mg and Ca were also visible. Although these elements do not interfere with the identification of heavy metals, it is best to remove them in order to obtain more concd. solns. This is done by pptg. the heavy metals as sulfides and dissolving the ppt. in 10% HCl. Since the heavy metals are suspected of performing a biological function as catalysts, the liver ext. was sepd. into 4 fractions, each of which was examd. for esterase and catalase and ashed separately for the spectrographic analyses. The bulk of the metals was present in the enzyme-free fractions. It is possible, however, that individual metals may occur in chem. compds. and are catalytically active only in some particular type of linkage. The spectrographic method does not furnish data on the existence of such compds. or their distribution between fractions rich and poor in enzymes. A. W. DOX

**The fate of diphenylene oxide in the intermediary metabolism of the rabbit.** ANAST. A. CHRISTOMANOS. *Z. physiol. Chem.* 181, 182-4(1929).—After subcutaneous injection of 7 and 8 g. of diphenylene oxide dissolved in olive oil, the rabbits excreted in the urine a considerable amt. of hippuric acid and a slightly increased amt. of BzOH as compared to the control period. Neither *o*-HOC<sub>6</sub>CO<sub>2</sub>H nor *o*-hydroxyhippuric acid was found. Evidently the (C<sub>6</sub>H<sub>5</sub>)<sub>2</sub>O breaks apart at the O-bridge, and the nucleus

carrying the O then undergoes destruction, leaving the other nucleus intact as BzOH which conjugates with glycine in the usual way. A. W. DOX

The relation of the vegetative nervous system to the action of pituitrin on fat metabolism. W. RAAB. *Z. ges. expul. Med.* 62, 366-72(1928); cf. *C. A.* 21, 3084.—The action of pituitrin on the blood fats is a reduction in the neutral fat content. The effect is weakly increased by ergotamine and not affected by atropine. The action of pituitrin on fat metabolism is through the tuber cinerium-cervical cord-sympathetic and liver. F. L. DUNN

Iodine content and the action of the thyroid secretion. EDMUND NOBEL. *Z. ges. expul. Med.* 62, 540-1(1928).—N. objects to Kreitmair's modification (*C. A.* 23, 623) of his method in detg. the amt. of thyroid material necessary to reduce the weight of 200-300 g. guinea pigs 10% in that it introduces the complications of feeding whereas N.'s method detg. the amt. necessary to produce death, and does not shorten the time of the test materially. F. L. DUNN

Enervation of the liver and the cholesterol in bile. B. E. GAISSINSKIL. *Z. ges. expul. Med.* 62, 678-87(1928).—About 23-28 mg. cholesterol per day is the normal output for dogs through a biliary fistula, and the fluctuations are not over 2-5 mg. Section of the sympathetic nerve supply increases the daily variations markedly, while section of the vagus has little effect or decreases the normal variations slightly. The output of cholesterol through the fistula does not parallel the blood cholesterol. G. emphasizes that variations in the sympathetic innervation of the liver can produce changes in cholesterol balance which are not reflected in the blood. F. L. DUNN

Results of hormone investigations. FREITAG. *Pharm. Ztg.* 74, 693-5(1929).—A brief review of results obtained during the past 40 yrs. W. O. E.

The effect of an excess of carbon dioxide in the inspired air before and after section of the vagi. Studies on the regulation of the respiration. I. SHOSETSU SASAKI. *J. Biophysics (Japan)* 2, 197(1927); *Collected Papers Physiol. and Biological Physicochem.* 4, 197-213(1928).—The respiratory changes induced by the inhalation of CO<sub>2</sub>-contg. air were tested on unanesthetized rabbits for 30-120 mins. before and after section of the vagi. With intact vagi the depth of respiration increases with more than 3% of CO<sub>2</sub>, while the frequency shows an increase with more than 5% of CO<sub>2</sub>. The CO<sub>2</sub> elimination is hindered by the CO<sub>2</sub> content in the inspired air. The O<sub>2</sub> absorption decreases also with CO<sub>2</sub> content, but its effect is less intensive than that on the CO<sub>2</sub> elimination. With both vagi divided, the frequency is not influenced by the CO<sub>2</sub> content of the inspired air, while the depth increases to its max. with more than 3% of the CO<sub>2</sub>. The CO<sub>2</sub> elimination and the O<sub>2</sub> absorption are diminished when the CO<sub>2</sub> is more than 4%. Thus Scott's conclusion (*J. Physiol.* 37, 308), that the depth of respiration is controlled by the CO<sub>2</sub> tension in the blood, while the frequency is controlled by the vagus reflex, was confirmed under conditions different from those of his expts. namely, without anesthesia and with the inspiration of CO<sub>2</sub>-contg. air for a long period. Respiration of man at rest and the effect of abnormal air breathed upon the respiration. II. *Ibid* 215-42.—Respiration expts. on a human individual showed that: The depth of respiration is augmented when the inspired air contains more than 2.5% of CO<sub>2</sub>, while the frequency is accelerated with more than 3.5%. The CO<sub>2</sub> elimination and O<sub>2</sub> absorption are depressed by an excess of CO<sub>2</sub> in the inspired air. The alveolar CO<sub>2</sub> tension has a tendency to decrease with the increased depth of respiration or else ventilation takes place spontaneously in the scope of physiol. variation. This suggests that, during the normal respiration, some factor other than the alveolar CO<sub>2</sub> tension controls the depth or ventilation, which in turn has an influence on the alveolar gaseous tensions. The alveolar CO<sub>2</sub> tension increases, when the inspired air contains more than 2% of CO<sub>2</sub>, accompanied by augmented ventilation. An insufficient O<sub>2</sub> supply excited the respiratory center to cause an augmentation of the depth of respiration, and this, in turn, results in a lowering of the alveolar CO<sub>2</sub> tension. The respiratory dead space increases when the depth of respiration increases spontaneously in the scope of its physiol. variation, or it is augmented by an abnormal content of CO<sub>2</sub> or an O<sub>2</sub> lack in the inspired air. C. R. F.

Hydrogen-ion equilibrium in the blood. III. Temperature effect on the amphoteric property of oxyhemoglobin. SATORU KATO. *J. Biophysics (Japan)* 2, 243-9(1928); *Collected Papers in Physiology and Biol. Physicochem.* 4.—If oxyhemoglobin acts as an amphoteric electrolyte, there should exist a CO<sub>2</sub> tension at which both the blood and its serum show the same H-ion concn., this being the isoelec. pt. of oxyhemoglobin. With defibrinated horse blood it was found that the  $p_H - p_{CO_2}$  curve

of the blood interests with that of the serum at the isoelec. point of oxyhemoglobin. In the range more alk. than this point, the blood is more acidic than the serum, when both are equilibrated with a common  $\text{CO}_2$  tension. In the more acidic range the relation is just the reverse. The isoelec. point of oxyhemoglobin coincides well with that found by cataphoresis. The mean  $p_H$  of this point is 6.95 at  $18^\circ$ , 6.82 at  $25^\circ$ , 6.75 at  $30^\circ$  and 6.57 at  $37^\circ$ . Thus the  $p_H$  at the isoelec. point is slightly acidic, and its deviation from neutrality increases with the rise in temp. C. R. FELLERS

**A new method of measuring the volume of the blood corpuscles.** II. KOZO HIROTA, *J. Biophysics* (Japan) 2, 283-91(1927); *Collected Papers in Physiology and Biol. Physico-chem.* 4.—In H.'s preliminary report (*C. A.* 21, 1284), corpuscular vol.,  $(V_\infty) = 1/b$ , where  $b = 0.03734$  at 2500 r. p. m. of the centrifuge, horse blood being used. Refinements in the centrifuge and calcn. of results by the method of least squares led to the establishment of the revised formula  $1/VT = a + b(t - t_1)$ , where  $t$  is the duration of centrifuging,  $VT$ , the observed corpuscular vol.,  $a$  and  $b$  are consts., and  $t_1$  is the initial time of observation. At 1500 r.p.m.,  $a = 0.3052$  and  $b = 0.03356$ ; at 2500 r. p. m.,  $a = 0.3525$  and  $b = 0.3734$ ; at 2700 r. p. m.,  $a = 0.3244$  and  $b = 0.03459$ . An error of only 0.1-0.2% was observed. The formula is not influenced by the inertia of the centrifuge. The method is applicable as well to the corpuscular suspension in a salt soln. as to the blood. Among several indirect methods which were compared, Stewart's cond. method as used by Suzue (*C. A.* 21, 1275) gave the best results although an unavoidable 5% error (too low) is always present. C. R. FELLERS

**Mode of combination of carbon dioxide in the blood.** K. HAYASI, Y. NISIMARU AND M. OKUYAMA. *J. Biophysics* (Japan) 2, 293-303(1927); *Collected Papers in Physiology and Biol. Physico-chem.* 4.—In order to det. whether or not the red blood corpuscles share in the transportation of  $\text{CO}_2$  from the blood to the lung tissues, a comparison was made of the  $\text{CO}_2$ -dissocn. curves of oxalated goat blood and plasma from the same sample of blood. The blood was brought into a Barcroft tonometer, filled with an air of a desired  $\text{CO}_2$  tension. The tonometer was slowly rotated in a thermostat at  $37^\circ$  for 10 mins. to equilibrate the blood with the gas. Then the sample was divided into 3 portions, one for  $\text{CO}_2$  content by Van Slyke's app., a second portion was passed into a Barcroft differential manometer for  $\text{CO}_2$  detn. on the whole blood, while a third portion was titrated electrometrically. The  $\text{CO}_2$  tension of the gaseous content of the tonometer was measured by means of the Haldane app. Every precaution was observed to prevent contact with atmospheric air, and to maintain body temp. The  $\text{CO}_2$ -carrying ability of the blood corpuscles is superior to that of the plasma, so that a considerable portion of the  $\text{CO}_2$  discharged from the blood in the lung is transported by the corpuscles. The supposition, that the  $\text{CO}_2$  is contained in the blood entirely in the forms of free  $\text{CO}_2$  and bicarbonate, is a mistake. A part of the  $\text{CO}_2$  is combined in an unknown form other than those mentioned above, as the exptl. data are at variance with the law of mass action applied to the  $\text{CO}_2$ -bicarbonate equil. established under the above supposition. C. R. FELLERS

**Problems of carbohydrate metabolism with special reference to the role of the liver.** F. FISCHLER. *Deut. med. Wochschr.* 55, 605-7(1929).—The chemical changes occurring during carbohydrate metabolism are discussed. ARTHUR GROLLMAN

**Amino acid catabolism.** III. The fate of the  $\omega$ -hydroxy derivatives of propionic, butyric, valeric and caproic acids in the phlorhizinized dog. RALPH C. CORLEY AND CARL S. MARVEL. *J. Biol. Chem.* 82, 77-82(1929); cf. *C. A.* 23, 2744.— $\gamma$ -Hydroxybutyric acid is a sugar former in the completely phlorhizinized dog, while hydracrylic,  $\delta$ -hydroxyvaleric, and  $\epsilon$ -hydroxycaproic acids are not. The view is supported that successive stages in the breakdown of the diamino acids may result in the acids with 1 less C, with an  $\text{NH}_2$  group in the  $\omega$  position, the corresponding  $\omega$ -hydroxy acids, and the corresponding dicarboxylic acids. ARTHUR GROLLMAN

**The role of the phospholipides of the intestinal mucosa in fat absorption.** With additional data on the phospholipides of the liver, and smooth and skeletal muscle. ROBERT G. SINCLAIR. *J. Biol. Chem.* 82, 117-36(1929).—During the absorption of fat there is a pronounced change in the compn. but not in the amt. of the phospholipide fatty acids of the intestinal mucosa and liver. There is no change in the amt. or compn. of these acids in the intestinal or skeletal muscles. It is suggested that absorbed fatty acids are transformed into phospholipide within the intestinal mucosa as an essential step in the resynthesis of neutral fat. ARTHUR GROLLMAN

**Studies of calcium and phosphorus metabolism.** II. The calcium excretion of normal individuals on a low calcium diet, also data on a case of pregnancy. WALTER BAUER, FULLER ALBRIGHT AND JOSEPH C. AUB. *J. Clin. Investigation* 7, 75-96(1929); cf. *C. A.* 23, 1171.—The neg. Ca balances were detd. on 13 normal individuals on a very

low Ca intake. It is shown that this neg. balance is an aspect of Ca metabolism which can be studied quantitatively under varying conditions. Observations in a case of pregnancy showed that the Ca excretion during gestation is essentially normal. III. The effects of the thyroid hormone and thyroid disease. JOSEPH C. AUB, WALTER BAUER, CLARK HEATH and MARION ROPES. *Ibid* 97, 137.—Patients with hyperthyroidism showed an increase of 23% in the excretion of Ca as compared to normal individuals. In myxedema, the Ca excretion was decreased. An increased Ca and P excretion also followed the administration of thyroid ext. to normal individuals. IV. The effect of the parathyroid hormone. FULLER ALBRIGHT, WALTER BAUER, MARION ROPES and JOSEPH C. AUB. *Ibid* 137-81.—In patients maintained on a const. diet contg. an inadequate amt. of Ca, parathyroid administration gradually increased the urinary Ca excretion without affecting the fecal excretion. The P level of the blood was primarily lowered by parathormone and there was an increased P excretion in the urine. N excretion was not affected nor were 2 ossifying hematomas affected by parathormone.

MILTON HANKE

Ovarian hormone and basal metabolism. GERTRUD KOEHLER. *Klin. Wochschr.* 8, 502-3 (1929).—Administration of ovarian hormone to patients with visible evidence of a disturbed ovarian function does not, in any case (8 cases), produce a change in the basal metabolism. The fact that it is impossible to raise the basal metabolic rate or to reduce the weight in cases of obesity that follow castration should of itself be sufficient evidence to prove that the ovarian hormone has little, or nothing, to do with these conditions. The hypophysis and the thyroid gland are probably the active agents. The obesity that follows castration is, therefore, probably not due to any direct action of the ovarian hormone but more likely due to the indirect action of the lack of this hormone upon the thyroid and hypophysis.

MILTON HANKE

Theories of hydrochloric acid formation in the stomach. FRANKLIN HOLLANDER. *J. Am. Inst. Homeopathy* 22, 311-21 (1929).—An accessory stomach (Pavlov pouch) was made in 5 dogs. By means of a catheter, the accumulated gastric juice was removed from this pouch in a period of 15 to 30 sec. This juice usually had a  $p_H$  of  $0.90 \pm 0.01$ , corresponding to 0.157 N or 0.55% HCl. Titration gave identical values for free HCl and total acidity, and a value of 0 for combined acidity. Apparently neutral chlorides were absent, and the juice was isotonic with the blood. When 2 portions of an isotonic NaCl soln. were sepd. by the skin of a recently killed frog, distinct evidence was obtained that hydrolysis occurred according to the equation  $\text{NaCl} + \text{H}_2\text{O} = \text{NaOH} + \text{HCl}$ . The HCl was transported to one side of the membrane, while the NaOH remained on the other side and was buffered by NaCl. The hypothesis is presented that HCl is secreted into the vacuole of the parietal cell by a similar process, and is then concd. to a certain extent, by reabsorption of  $\text{H}_2\text{O}$  from the vacuole until the secretion is isotonic with the blood. A comprehensive review and bibliography are included.

Passage of arsenic through placental circulation. ERNST ZIEMKE. *Deut. Z. ges. gericht. Med.* 13, 217-25 (1929).—As passes through the placental circulation to the fetus, but only in very small quantity. The placenta when functioning normally protects the fetus from excessive amts.

FRANCES KRASNOW

Observations on the hydrogen-ion concentration of the alimentary canal of the albino rat. G. R. McROBERT. *Indian J. Med. Research* 16, 545-52 (1928).—The gastrointestinal contents of normal albino rats are acid except in the lower part of the ileum where they are alk. Addn. of small quantities of tomato, lettuce or milk to food is sufficient to prevent the development of alky. The absence of vitamin B does not alter the  $p_H$  in the bowel.

F. K.

The amount of the alcohol extract according to sex from the brain of the albino rat. CHIA CHU WANG. *J. Comp. Neurol.* 47, 67-73 (1929).—The ext. is largely myelin, which is present in the brains of both sexes in the same proportion.

F. K.

Experiments with acids. W. BURRIDGE. *Quart. J. Exptl. Physiol.* 18, 1-9 (1928).—The H ion exerts 2 independent actions on the excitability of the frog heart; "a depression mediated through disorganization of Ca function and an augmentation mediated through changes of colloid aggregation." Changes of  $p_H$  between  $p_H$  8 and  $p_H$  7.0 gave only depression, the augmenting action of an acid being developed beyond  $p_H$  7.0. The actions of lactic and butyric acids were not wholly accounted for in terms of their H ion, especially when used as very dil. solns.

FRANCES KRASNOW

**Mineral composition of blood platelets and white blood cells.** G. ENDRES AND L. HERGET. *Z. Biol.* 88, 451-64(1929).—There is a close chemical relationship between the blood platelets and the white blood cells. The  $H_2O$  content as well as the quant. and qual. salt content differs only slightly. Both show mineral compn. different from the plasma and erythrocytes. Like the red cells, they contain less Na and Ca but more K than plasma. The P (inorg.) is higher and the bicarbonate low. F. K.

**Dehydration of lactic acid.** AMANDUS HAHN, E. FISCHBACH AND W. HAARMANN. *Z. Biol.* 88, 516-22(1929); cf. C. A. 23, 1654.—By means of a specific dehydrase, different from succinic acid and malic acid dehydrase, lactic acid is changed to pyroracemic acid in the presence of methylene blue. FRANCES KRASNOW

**Experimental investigation on glycogen of the internal ear of the guinea pig.** VI. The changes of glycogen in the internal ear due to the injection of insulin. HYOSAKU TANAKA. *Sei-i-Kwai Med. J.* 47, No. 12, 1-11 (In English, 1-2) (1929).—By use of histological methods, it is shown that insulin has the same effect upon the glycogen content in the internal ear of guinea pigs as upon the glycogen of the liver or other organs. VII. The post-mortal changes of the glycogen content in the internal ear. *Ibid* 12-26 (in English, 2-3).—After death of an animal, the glycogen of the internal ear disappears nearly completely within 30 mins. W. D. LANGLÄV

**The rotatory power of serum as a function of the temperature.** P. LÉCOMTE DU NOTY. *Compt. rend.* 188, 660-2; *Science* 69, 552-3(1929).—The destruction of the complement in serum heated to  $56^\circ$  is accompanied by a definite min. viscosity, suggesting a chem. change in the protein mols. The specific rotation for normal horse serum between  $0^\circ$  and  $50^\circ$  has a const. value of  $-58^\circ$  for green light. Above this temp. the rotatory power increases slowly, but above  $59^\circ$  this change is rapid. At the same time there is an obscuring of the light after a few minutes that prevents readings on a polariscope. It is suggested that the structure of the mols. changes at a rate that increases progressively with the temp. and this change corresponds with the suppression of the complement of the serum. The change in viscosity and the darkening of the polariscope reading may result from a change in dispersion and hydration of the proteins following the chem. change indicated by the increase in rotatory power. AMY LEVESCONTE

**The utilization of pentoses in the animal organism.** P. THOMAS, A. GRADINESCU, AND MILE. R. IMAS. *Compt. rend.* 188, 664-6(1929).—A detn. was made of the increase in glycogen of fasting frogs when they received varying quantities of xylose or arabinose. If each mol. of pentose furnishes 1 mol. of lactic acid which is then changed to glycogen, the max. of glycogen produced should be 54% of the pentose. Arabinose furnished 54.9% and xylose 51.24% of glycogen which is within exptl. error. More xylose than arabinose is eliminated by the kidney. AMY LEVESCONTE

**The fluctuations of the capillary blood sugar in normal young men during a twenty-four hour period (including a discussion of the effect of sleep and of mild exercise).** HARRY C. TRIMBLE AND STEPHEN J. MADDOCK. *J. Biol. Chem.* 81, 595-610(1929).—"The concn. of sugar in the capillary blood of 9 normal young men living upon their usual diet has been detd. at hourly intervals over a 24-hr. period. The following av. hourly values from 8 A. M. to 11 P. M. were found: 97, 121, 99, 101, 103, 132, 118, 113, 103, 96, 93, 130, 134, 126, 103, 99 mg. per 100 cc. In each individual the concn. was maintained at a very const. level while at rest in bed during the night. This level varied slightly with the individuals but in no case did it differ widely from the group av. of 94-5 mg. %. This was approx. the value found also as the mean concn. of sugar in the capillary blood of a much larger group of young men in the post-absorptive condition. Therefore, it is concluded that sleep does not cause a significant change in the blood sugar concn. There was some indication also that after mixed meals the capillary blood sugar returns to fasting levels somewhat more slowly than others have found after the ingestion of pure carbohydrate. Various forms of mild exercise did not produce any significant change in blood sugar. Only as the intensity of the exercise was increased markedly was any indication of an increase of sugar concn. obtained." A. P. LOTHROP

**Calcium metabolism and parathyroid hormone in different kinds of animals.** M. TRÖLLDTE. *Krankheitsforsch.* 6, 397-492(1928).—There appear to be specifically different means of regulation of the Ca metabolism in different species of animals. Parathyroid hormone, injected subcutaneously into dogs, cats and rabbits, causes a marked increase in the Ca content of the blood serum. However, the course of the increase in the Ca concn., as indicated by plotted rate curves, is uniquely characteristic for each of the animal species. A similar, but temporary, effect follows the injection of a soln. of  $CaCl_2$ . Repeated injection of the hormone into cats and rabbits did not show a

summation of effect as has been reported by Collip to occur in dogs. A decrease in galvanic sensitiveness, especially in the cathodic opening contraction, is assocd. with the increase in the Ca concn. which follows the injection of the hormone. This occurs almost simultaneously with the increase in the Ca concn. in rabbits, but is somewhat retarded in dogs.

E. R. MAIN

The contractile activity of embryonic heart transplants under normal conditions and under the influence of certain hormones. VINCENZO BISCEGLIE. *Arch. sci. biol.* 13, 53-72(1929).—The contractile activity of chick embryonic heart transplants of different age, and the change in activity caused by insulin, thyroid ext., and follicular liquid, were studied. Insulin produced a depression and aq. exts. of thyroid, an increase in activity. Follicular liquid caused a more or less rapid diminution of the frequency followed by a decrease in the intensity of the contractions.

PETER MASUCCI

The action of calcium on the endocrine glands. GIORGIO SCHREIBER. *Arch. sci. biol.* 13, 127-57; *Boll. soc. ital. biol. sper.* 4, 61-3 (1929).—Enriques and collaborators have demonstrated a correlation between endocrine activity and bone fracture and have advanced the theory that the Ca salts thrown into the circulation by osteolysis excite the endocrine system. The aim of this investigation was to explain the action of Ca on the endocrine system by injecting 1%  $\text{CaCl}_2$  soln. into guinea pigs for 8-12 days and noting its effect on the wt. and on the histological picture of the thymus, thyroid and suprarenal glands. The action of Ca on the wt. of these glands was manifested by the following facts: (1) The thymus increased in wt. in the old animals when compared with the controls. (2) The suprarenals diminished in the young but increased considerably in the adult. (3) The thyroid increased in all ages, although to a lesser degree than the other two glands. Histologically, the changes noted in the thymus indicated an increased functional activity similar to that observed in fractures; this was noted only in young animals which showed an increase in wt. In the suprarenals, the increase in wt. was directly related to the marked increase in vol. of the reticular zone, whereas the other zones remained unaltered. The increase in vol. of the reticular zone was followed by the appearance of hyperpigmentation phenomena in that same zone. Conclusion: The thymus gland, in view of the perfect analogy of its behavior in fractures and in its response to Ca injections, is stimulated by Ca; the suprarenal gland however, presents an entirely different correlative picture in fractures than it does to Ca injections.

PETER MASUCCI

Modifications of the blood while sojourning in high mountains in relation to the function of the spleen. A. CHIATELLINO AND S. GOLDBERGER. *Boll. soc. ital. biol. sper.* 4, 7-9(1929).—At high altitudes in animals deprived of the spleen the increase in red blood corpuscles is markedly greater than in the normals; the same is true with regard to hemoglobin except that the increases are not so marked. Therefore, the spleen plays a part in the functioning of bone marrow.

PETER MASUCCI

Respiratory exchange in the experimental pneumothorax and oleothorax. GIULIO CERUTI. *Boll. soc. ital. biol. sper.* 4, 17-9(1929).—The variations which the respiratory exchange undergoes as a result of the suppression of the gaseous exchange in one of the lungs obtained with the pneumothorax ( $\text{N}_2$ ), or by introducing vaseline in the pleural cavity, was detd. Dogs were used; the detn. of  $\text{CO}_2$  and  $\text{O}_2$  was made with Haldane's app. In the animals with pneumothorax, respiration increased in proportion to the pleural pressure and returned to normal as the pressure decreased. Dogs with oleothorax did not behave similarly; dyspnea persisted always. Data are also given for pulmonary ventilation and  $\text{O}_2$  consumed under various exptl. conditions.

P. M.

The action of amino acids on the blood vessels of homeotherms. GIUSEPPE RUSSO. *Boll. soc. ital. biol. sper.* 4, 44-6(1929).—The action of amino acids on the blood vessels of mammals was studied by perfusing isolated lung, kidney and heart of the dog in Locke soln. by itself and in Locke soln. plus 0.1% glycolol or asparagine. Both sets of solns. contained an equal amt. of phosphate buffer at  $p_H$  7.2. Amino acids added to perfusion fluids in concns. not much stronger than those normally found in the blood do not have any marked sp. action on the vessels.

PETER MASUCCI

The optic qualities of the vitreous humor (absorption of ultra-violet). TETSUO ABE. *Arch. phys. biol.* 6, 1-21(1927).—The natural body of  $p_H = 8.2$  presents absorption near  $\lambda$  260-270, not identical with that of the crystalline humor, 276, and of the white of egg, 276. If the vitreous humor is left to itself, the  $p_H$  increases and the absorption decreases; this is probably due to the transformation of a mucinogenous substance into mucin. At const.  $p_H$  the spectral evolution can be observed as a function of time.

A. E. MEYER

Experimental study of certain relations between the real acidity and the leucocytic reaction. TERESA SARIANO. *Rev. farm. (Buenos Aires)* [2], 2, 16-27(1929).—Leuco-

cytes were observed by injecting suspensions of carmine in liquids of detd. acidity into frogs. The liquid was withdrawn later and the leucocytes were observed by the comparative method with indicators under the microscope. The  $p_H$  of protoplasm was 8.2–8.4, of granules 7.7–7.9, of vacuoles 7–7.5. No relation exists between the acidity of the leucocytes and that of the injected liquid. The  $p_H$  of the exudate is influenced by the acidity of the injected liquid only for 48 hrs.; after that it is 8. Liquids injected at  $p_H$  9–10 contain the largest amt. of leucocytes; the best phagocytosis is obtained at  $p_H$  8–10; the best mobility is obtained at  $p_H$  10. Mobility and phagocytosis are not related.

**Hyperglobulism in voluntary apnea.** ARTURO A. BRUNO. *Rev. sud-americana endocrinol., inmunol., quimioterap.* 11, 679–81(1928).—In need of O, red corpuscles are expressed from the spleen, increasing the content in Fe and cells in the blood and its sp. gr.

**Female sexual hormones. A biological and experimental study.** FRANCISCO GARCIA TREVIÑO. *Rev. sud-americana endocrinol., inmunol., quimioterap.* 11, 763–76(1928).—Serum from pregnant women produces estrus in immature rats and a considerable enlargement of the uterus. The active substance is resistant against heat, sol. in EtOH, and apparently diffusible. One cc. of serum contains 10 biol. (inquire) units. The substance is produced not only in the ovary, but in the placenta and possibly in the uterus.

**Preexistence of a vagotropic substance in the blood, the lymph and the cerebrospinal fluid and its probable identity with the vagal substance of Loewi.** G. VIALE. *Rev. sud-americana endocrinol., inmunol., quimioterap.* 11, 840–5(1928).—The vagotropic substance is not identical with choline or acetylcholine. A vagotropic substance was found in blood, etc., that is not pptd. by phosphotungstic acid. From expts with dogs it is concluded that the substance is a normal constituent of the blood and produced in larger quantity under the action of the vagus.

**The leucocytic reaction and chloremia during digestion.** ARTURO A. BRUNO. *Rev. sud-americana endocrinol., inmunol., quimioterap.* 12, 173–85(1929).—During digestion, the Cl in the blood is increased, but in the serum it is lower. The transportation from the tissues to the stomach is performed by the corpuscles. The blood in the portal vein contains more Cl and fewer corpuscles after meals. The leucocytosis is not strictly related to the chloremia. As emotion produces leucopenia in dogs, in all expts. connected with the application of substances by force the emotional factor must be considered. HCl, lactic acid, AcOH and KCl may produce leucocytosis.

**The lactic acid excretion in the urine and sweat during football games.** I. SNAPPER AND A. GRÜNBAUM. *Biochem. Z.* 206, 319–33(1929).—Before the game only a trace of lactic acid was found in the urine of 57 players. After the game at most only traces of albumin appeared in the urine of 74 players and only 2 instances of glucosuria were noted. In 6 out of 55 urines when the game was played on a warm day, more than 60 mg. lactic acid was found, whereas on cold days 16 out of 32 urines contained more than 60 mg. lactic acid. This difference in appearance of lactic acid in the urine depending upon the temp. of the air is due to the excretion of the lactic acid in the sweat. During a football game lasting 1.5 hrs. on a hot day 1.1–2.2 g. lactic acid was eliminated in the sweat; also in about half the players 2–4 g. Cl was eliminated. The first sweat contains more lactic acid than the sweat at the end of the game. The lactic acid concn. of sweat can be ten times as great as that of the blood.

**Insulin and depot nourishment.** A. LÖW AND A. KRČMA. *Biochem. Z.* 206, 360–9(1929).—Studies on the carbohydrate content of the liver, muscles and omentum fat of mice lead to the conclusion that the fat tissue plays an important role in the glucose metabolism and that not only is carbohydrate converted to fat but fat is also changed to carbohydrate.

**The upper limit of hydrogen-ion concentration and bicarbonate concentration of urine.** FRITZ MAINZER. *Biochem. Z.* 207, 159–66(1929).—Under consideration of the  $CO_2$  tension the  $p_H$  of the urine on the alk. side cannot exceed the  $p_H = 8.3$ . The bicarbonate elimination at const.  $CO_2$  pressure is a simple function of the  $p_H$ , and the max. bicarbonate concn. should be about 1200 vol. % (= 536 millimols). This has been proved by means of expts. where alkali was administered orally to 5 human subjects and where alkali intoxication was produced in dogs with intravenous bicarbonate injections. In these expts. the urine  $p_H$  actually reached a max. value of 8.30, but the bicarbonate concn. did not exceed 416 vol. % (= 186 millimols). Evidently other factors control the limiting bicarbonate concn.

**The lipid-soluble and lipid-insoluble forms of the ovarian hormone (feminin).**

E. GLIMM AND F. WADEHN. *Biochem. Z.* 207, 361-7(1929).—The estrus-producing substance is present in the urine as an ether-sol. and as an ether-insol. form, the former being definitely in a preponderating quantity. Prolonged boiling of the urine in alk. medium as well as of highly purified artificial solns. converts the ether-sol. component into an ether-insol. form. The nature of the ether-insol. substance seems to be influenced by the duration of heating. It is not clear yet, however, if the ether-insol. compd. present in urine and the substance produced artificially are identical. The insol. substance resulting from brief boiling in alk. medium can be changed to the ether-sol. form again by treating with acid.

S. MORGULIS

The ionic composition of mother and fetus. SHIGERU HAYASHI. *Biochem. Z.* 207, 432-6(1929).—Under proper nourishment the organism of pregnant female rats retains its K, Ca, Mg and P contents in liver, heart and bones. The K:Ca ratio in the liver rises perhaps 10% as a max., whereas in the heart it diminishes in consequence of an increased Ca. The bones retain their Ca and Mg contents unimpaired. The Ca:Mg ratio in the pregnant rat is somewhat less than in the normal animal. The compn. of fetuses from 17 mm. in length (approx. 12 days old) as regards the K and Mg content is practically unchanged, only in the earliest periods the results being somewhat high. The Ca content naturally increases with the growth of the skeleton and reaches a max. at time of birth. The amt. of P likewise increases during development, but the max. content is attained before that of the Ca.

S. MORGULIS

Ovulation during pregnancy induced by hypophyseal anterior lobe hormone. BERNHARD ZONDEK AND S. ASCHHEIM. *Endokrinologie* 1, 10-22(1928).—Under the influence of hypophyseal hormone of the anterior lobe, the ovary of the pregnant mouse is stimulated to new functional activity: follicles ripen, burst and the eggs pass into the tubes. Some of the eggs in the tube possess a good nucleus; in some the nucleus is resolved into chromatin shreds, but in most of them it is fragmented and degenerated. In the ovary besides the corpora lutea graviditatis there are also young corpora lutea coming from newly ruptured follicles. In the uterus there are live fetuses. It follows thus that the anterior lobe of the hypophysis hormone is effective in awakening ovulation in the state of pregnancy.

S. MORGULIS

Ovarian hormone and blood calcium. MAX REISS AND KARL MARX. *Endokrinologie* 1, 181-4(1928).—Application of the ovarian hormone causes a drop in the serum calcium level. There seems also a possibility that the extent of the drop depends upon the dose. The Ca level rises again when the hormone treatment is discontinued.

S. MORGULIS

The water and iodine content of the thyroid gland of domestic animals (ox, cow, calf, goat, sheep) of Aostatales and Umbrien. OSW. POLIMANTI. *Endokrinologie* 1, 401-11(1928).—The fresh thyroid gland of animals from Umbrien is 3.47 g. heavier than that of animals from the Aostatal region, but the wt. of the dry substance is only 1.489 g. greater. It is suggested from this fact that the Umbrien domestic animals have a more highly functional gland. The iodine content in the thyroid of full-grown cattle is considerably larger than that in the young (cow 0.79 mg., ox 0.82 mg., calf 0.50 mg. I per g of dry gland) and is greater in the Umbrien than in the Aostatal region (0.70 mg. and 0.52 mg., resp.).

S. MORGULIS

Ovarian hormone and blood cholesterol. SHIGEKI MORI AND MAX REISS. *Endokrinologie* 1, 418-21(1928).—The ovarian hormone causes a rise in the blood cholesterol.

S. MORGULIS

The calcium content of the blood and blood plasma on partially parathyroidectomized dogs and determinations of the blood calcium content in some patients with tetany symptoms. G. F. J. M. BÄR. *Endokrinologie* 1, 421-30(1928).—A dog whose 3 parathyroids were removed showed even 4 yrs. later definite parathyroid insufficiency symptoms although it was on a Ca-rich food. It is suggested (though the analytical data do not seem to confirm this) that the parathyroid hormone regulates the blood-plasma Ca by transferring Ca to the red cells. Following a hypoglycemic dose of insulin, the Ca content of the corpuscles increased from 0 to 5.6 mg. %. In 2 normal persons the blood plasma Ca was found to be 9 mg. % and that of the red cells 2-25 mg. %. The results in disease are variable.

S. MORGULIS

Climacteric hypertony. EUGEN V. RUTICH. *Endokrinologie* 3, 255-62(1929).—The cessation of ovarian function is not the primary cause of climacteric hypertony but is a stimulus or possibly a releasing factor, which in the constitutionally disposed organism increases the liability of the vegetative nervous system. It promotes changes in the colloidal relations which ultimately result in definite hypertony. Menformone glanduovin and glandofolin do not permanently affect the climacteric hypertony.

S. MORGULIS

**The metabolism of nitrogen in the embryos of birds.** M. H. TARGONSKI *Bull. intern. acad. polonaise* 1927 B, 1277-1300.—The amniotic and the allantoic fluids from hen eggs were analyzed for P, S, uric acid, urea,  $\text{NH}_3$ , creatine and oxyproteic acid. Uric acid is present after the 6th day. The ratio between P and N decreases in proportion to the development of the embryo: 10th day  $\text{P/N} = 0.43$ ; 18th day  $\text{P/N} = 0.12$ ; S/N the 14th day = 0.067; 18th day  $\text{S/N} = 0.11$ . In the vitellin  $\text{P/N} = 0.057$ . Catabolism of P compds. is more rapid during the early than the later stages. Between the 8th and 12th days  $\text{NH}_3$  can be detected. The min. amount has not been detd. The av. amt. of N at the end of the 10th day in the amniotic liquid is 0.34 mg., increasing to 1.06-1.27 mg. on the 14th day, and to 110 mg. on the 16th day. The non-protein N at the 16th day is 3.1-3.9 mg. The liquid accumulated is food for the fetus toward the end of fetal life. The ratio between amniotic N and allantois N up to the 14th day is 0.2; on the 16th day, 7; on the 18th day, 4.5. The allantoic liquid was treated with phosphotungstic acid. On the 12th, 14th, 16th and 18th days, resp., the % of the total N pptd. by phosphotungstic acid was 40.2, 51, 65.1 and 43.2. The percentage of N that was present as uric acid during the four periods was 43.5, 50, 68.1, 38.6. The urea N in urea in this same period showed little variation. The amino acid N was 8% of the total N. Traces of  $\text{NH}_3$  were found but no oxyproteic acid. There is agreement with the finding of Needham of  $\text{CO}(\text{NH}_2)_2$ , but not in the findings of uric acid. The ratio between anabolism and catabolism of purines is the same as that found by Mlle Aznerowna between the 10th and 18th days. GEO. W. MUHLEMAN

**The permeability of muscles to electrolytes during work and in a state of repose.** A. WOJTCZAK. *Bull. intern. acad. polonaise* 1927B, 1253-76.—The inorg. constituents in the muscles of frogs are K (0.3%), P(0.12%), Na(0.05%), Ca and Mg(0.02%) and Cl (0.04%). This compn. is maintained by absorption from the exterior due to the exterior protoplasmic compn. of the muscle. Contraction makes the exterior coating more permeable to the inorg. constituents of the muscle. K and Ca in the soln. activate the absorption of glucose. Muscle in the nutrient soln. contg. no glucose lost K during work; it lost P during repose and contraction but more during contraction; Ca was absorbed during repose and work. If glucose is present in the nutrient soln., much less K and P are lost. Fructose has the same effect. G. W. M.

**Excretion of dyes by the normal liver and the kidneys. I. Their relation to the diffusibility of dyes.** YOSHINORI TADA. *Acta Schol. Med. Univ. Imp. Kioto* 11, 193-229(1928).—According to T. the generally accepted theory that the excretion of dyes by the kidneys and by the liver depends solely on the phys. properties of the dyes leaves 2 problems unexplained, which T. attempts to solve in these investigations and in those to follow. The 1st one is whether the chem. constitution of the dyes has an influence on the excretion, while the 2nd problem is concerned with the fate of those dyes whose colloidal mols. are large and therefore cannot be excreted by the liver or the kidneys. Dogs served as test animals. A biliary and a urinary fistula was established and 1 cc. per kg. body wt. of a 1% dye soln. or, in case of small soly., of a satd dye soln. was injected into the ear vein of the animal narcotized by novocaine. Bile and urine were collected and the amt. of dye present was detd. colorimetrically. Most of the 44 acid and 7 basic dyes used were of known chem. constitution. In some cases their basic or acid character was established according to the method of Michaels and Shoji. The diffusibilities of many dyes were detd. according to the method of Schulemann; a 5% soln. of agar was used, however, instead of a 2% soln. of gelatin. It was observed that, in general, acid dyes of great diffusibility appear early in the excreta; that the velocity of their elimination was relatively great; and that their concn. in the bile and urine was high. These relations, however, could not be noted with basic dyes. Although in general the dyes of poor diffusibility were sparingly excreted by the kidneys, some dyes of great diffusibility were found that were not eliminated in the urine. The majority of the dyes, especially those of slight diffusibility, were excreted by the liver. As a rule, the dyes appeared in the urine earlier than in the bile. Dyes of great diffusibility appeared earlier in the urine than did dyes of small diffusibility. A certain relation existed between the amt. of dye excreted by the liver and that excreted by the kidneys; in case that the dye was only slightly eliminated in the urine, it was largely excreted in the bile and *vice versa*. The fate of the few dyes not excreted by either liver or kidneys could not be ascertained. Besides the diffusibility, the acid or basic character of the dye exerts a great influence on the quantities excreted, the elimination of basic dyes being generally very incomplete. The chem. constitution plays an important role. With the acid dyes, the trisazo dyes were eliminated in small quantities only, while most of the disazo dyes and dyes of the Sansen series were excreted solely by the liver. II. The compensative function of the kidneys of animals

for eliminating dyes after ligation of the common duct. *Ibid* 231-41.—A urinary fistula was established in dogs weighing 7 kg. and the common duct ligated. After recovery from the operation 7 cc. of a 1% dye soln. was injected into the ear vein of these animals (I) and of normal control dogs (II). Dyes were selected which under normal conditions were eliminated mainly or entirely by the liver. The urine was collected and analyzed. It was observed that when the excretion of the dye was 0 in II, it was also 0 in I. When the dye was excreted in II, it was also excreted in I, but in much increased amts. The max. dye concn. in the urine and the amts. of dye eliminated per time unit did not exceed, to a large degree, those encountered in II. The time of excretion, however, was distinctly prolonged. There is a certain limit to the dye-eliminating capacity of the kidneys, which cannot be surpassed as long as there is no change in the concn. of the dye in the blood. The time required for the complete elimination in I was inversely proportional to the increase of the max. concn. in the urine. III. The compensative function of the liver in the elimination of dyes in animals (in which the renal arteries and veins are ligated). *Ibid* 243-52.—Four dyes were selected which under normal conditions were mainly or entirely excreted in the urine. Dogs with a biliary fistula weighing about 10 kg. were divided in 2 groups. Seven cc. of a dye soln. was injected into the 1st group (I). The 2nd group (II) received first an injection of 0.7 cc. of a soln. of 2.0 g. of pantopon and 0.03 g. scopolamine in 50 cc. of water. After the dogs had fallen asleep, 7 cc. of dye soln. was injected. Several days later these animals were narcotized with the pantopon-scopolamine mixt. and Et<sub>2</sub>O and the renal arteries and veins and the urethras ligated at both sides. Then 7 cc. of dye soln. was injected. The usual measurements were made in all instances. It was noticed that narcosis caused a decrease in the quantity of bile excreted. In most cases, however, the concn. of the dye in the bile increased at the same time; thus the amts. of dye excreted remained about the same as those excreted by I. The amts. of bile produced by II after narcosis did not differ greatly from those produced after narcosis and operation. When the results obtained in the dogs of group II in the 2 stages mentioned were compared, it became evident that dyes not excreted by the liver under normal conditions were also not excreted in the bile after ligation of the urethras and the renal arteries and veins. The concn. of the dye in the bile and the amt. excreted per time unit did not show any marked increase after the operation; however, the time of elimination was much prolonged. Thus the total amt. excreted by the liver was much greater than normally. The eliminating capacity of the liver is limited and influenced by the concn. of the dye in the blood. The time required for the complete compensative elimination was inversely proportional to the increase of the max. concn. of the dye in the bile. IV. The relation between the concentration of dyes in the blood stream and the concentration of excreted dyes. *Ibid* 253-66.—The expts. were carried out with 6 dyes on dogs with urinary and biliary fistulas. The animals were kept under such conditions as to render the output per time unit of bile and urine as const. as possible. A certain quantity of the dye soln. was injected into a dog. One or 2 days later a quantity of dye soln. larger than the 1st one was injected. The expt. was repeated 2 more times with increasing quantities of dye soln.; the amts. of dye excreted each time were detd. as usual. The dye concn. in the bile and urine rises with increasing dye concn. in the blood, but even after ligating one of the organs in question, the excretion through the other organ cannot surpass a certain max. The amts. excreted are different for different dyes, but with the same dye the amts. excreted are const. as long as there is no change in the concn. of the dye in the blood. The ratio between the total amt. of dye eliminated in the bile and that eliminated in the urine is const. This ratio is not affected by changes in the concn. of the dye in the blood or the amts. of dye injected into the blood stream as long as there enters no factor that produces an abnormal change in the amt. of dye circulating through the liver and kidneys.

G. SCHWOCH

The excretory function of the stomach. II. The elimination of urotropine through the mucous membrane of the stomach. GIOVANNI DE TONI. *Biochim. terap. sper.* 7, 257-63 (1928); cf. *C. A.* 22, 2599.—Rabbits fasting for 24 hrs. were used for the 1st series of the expts. Different quantities of a 40% urotropine soln. varying from 1 to 6 cc. were injected into the marginal ear vein of the animals. Immediately afterward, 0.20 cc. of a 0.1% histamine soln. was administered subcutaneously in order to increase the flow of the gastric juice. Thirty mins. after the injection of the urotropine the juice was removed and filtered. When the quantity injected was larger than 2 millimols per kg. body wt., the presence of urotropine in the stomach could be demonstrated with Br water or with HgCl<sub>2</sub> or with Burnam's test as modified by Breunig. In a 2nd series of expts. the urotropine was administered to young, healthy children by intramuscular injection or by rectum. The drug was found present in the stomach

after 1 hr., when the amts. injected intramuscularly were larger than 0.5 millimol per kg. body wt. When the urotropine was given by rectum, the min. doses required to cause a pos. test after 1½ hrs. varied between 1 and 1.5 millimols per kg. Urotropine introduced parenterally into the body is converted into HCHO already in the stomach. This may account for the gastric troubles frequently encountered in clinical cases after injections of urotropine. G. SCHWOCH

**Regulation of metabolism. XI. Peculiar position of the egg cell as regards oxygen utilization.** ERNST WERTHEIMER. Univ. Halle a. S. *Arch. ges. Physiol.* (Pflüger's) 221, 119-38(1928); cf. C. A. 22, 4156.—After strychnine poisoning the loss in carbohydrate by the liver, muscle, heart and brain is very great, while the carbohydrate of the egg cell is not diminished. In a similar way adrenaline and insulin reduce the glycogen of the tissues but not that of the egg. The compn. of the egg cell is also less influenced by temp and anoxybiotic condition than is the case with other cells. G. H. SMITH

**Is the amount of glycogen changed in the tonic contraction of striated muscles?** ERNST WERTHEIMER. *Arch. ges. Physiol.* (Pflüger's) 221, 139-43(1928).—In 15 of the 33 preps. studied no loss in glycogen occurred; in the other 18 cases it was reduced by an av. of 28%. G. H. SMITH

**Permeability of animal membranes for dyestuffs.** ERNST GELLHORN. *Arch. ges. Physiol.* (Pflüger's) 221, 230-46(1928).—Diffusible acid dyestuffs penetrate membranes without regard to their lipid soly. There is no strict relation between rate of penetration and the size of the particles of the dyestuff. The muscle membrane is penetrated by acid dyestuffs more quickly than is the skin, while basic dyestuffs enter the skin more readily. G. H. SMITH

**Fetal development of blood in cattle. I. Average volume and average dry substance and hemoglobin content of the red cells in cattle.** D. VON DESER. *Arch. ges. Physiol.* (Pflüger's) 221, 321-6(1928).—The dry substance of the red cell is 1.97%, and of the dry material 85.9% is hemoglobin. The av. vol. is 52.2μ³. **II. Average volume and average dry substance and hemoglobin content of the red cells of the fetus.** *Ibid* 327-33(1928).—The properties of the red cells change throughout the period of fetal life. G. H. SMITH

**Lactic acid metabolism of the surviving extremity.** A. BORNSTEIN AND ERICH SCHMUTZLER. *Arch. ges. Physiol.* (Pflüger's) 221, 395-9(1929).—The perfused, resting dog leg does not give up lactic acid to the perfusion fluid, even if insulin or alc. is added, but if oxidation is inhibited by NaCN, there is a marked increase. When lactic acid is added in gradually increasing amts. to the perfusion, the resting leg (per kg.) can utilize between 0.075 and 0.1 g. of lactic acid per hr. G. H. SMITH

**Blood supply and metabolism of the working mammalian muscle: The surviving extremity and the heart-lung preparation.** A. BORNSTEIN AND H. F. ROESSE. *Arch. ges. Physiol.* (Pflüger's) 221, 400-9(1929).—Like the heart-lung prepn., the active perfused dog leg does not yield lactic acid or NH₃ to the perfusion fluid, but if the O supply is inadequate, both preps. give up both substances. Vasoconstricting substances of the serum are slowly destroyed in the resting perfused leg. G. H. SMITH

**The heart hormone. The active principle of Haberlandt's frog heart hormone.** R. RIGLER. *Arch. ges. Physiol.* (Pflüger's) 221, 509-25(1929); cf. C. A. 23, 1169.—The frog heart hormone of Haberlandt is composed of 2 active principles, K with chronotropic action, and something with inotropic effect corresponding to Clark's substance. G. H. SMITH

**Regulation of carbohydrate metabolism. Excretion of insulin through the kidney.** ALEXANDER PARTOS. *Arch. ges. Physiol.* (Pflüger's) 221, 562-70(1929); cf. C. A. 23, 869.—Insulin is a normal component of human and rabbit urines. In the fasting rabbit no insulin is excreted, thus explaining the behavior of injected sugar in the fasting animal. During the hyperglucemic stage the urine contains no insulin, but as soon as the blood pressure falls excretion begins. Absorbed carbohydrate is an adequate stimulus for insulin production, and the amt. of glucose to be found in the liver after a meal contg. abundant carbohydrate depends upon the amt. of insulin present. In human as well as in exptl. pancreatic diabetes there is no insulin in the urine. G. H. SMITH

**Hormone of heart action. XI. Action of the heart hormone preparation on the frog heart.** L. HABERLANDT. *Arch. ges. Physiol.* (Pflüger's) 221, 576-90(1929); cf. C. A. 23, 1169.—The heart hormone prepn. was still active after being rendered completely free of histamine. G. H. SMITH

**Comparison of the membrane structure and the permeability of the red blood cells of different mammals.** RUDOLF MOND AND HEINZ GERTZ. *Arch. ges. Physiol.* (Pflü-

ger's) 221, 623-32(1929).—With respect to permeability velocities the types of red cell tested may be expressed man > pig > horse > sheep, goat, cow. G. H. SMITH

**Formation of urine in the frog kidney.** XVII. Dyestuff secretion by the second section. FERDINAND SCHEMINZKY. *Arch. ges. Physiol.* (Pflüger's) 221, 641-91(1929).—Tubule cells loaded with dyestuff after vital staining of the whole animal show no impairment of function. When the isolated kidney is perfused with neutral red, it requires a much higher concn. of dyestuff in the arterial system than in the venous to obtain the same effect, and different sections are stained. From the vein neutral red passes readily to the urine; cyanole passes readily from the artery. As regards the vascular supply, the fourth section of the tubule and the glomerulus represent one system; the second section constitutes a second one; and the two systems do not behave in the same way in dyestuff secretion. G. H. SMITH

**Work and acid production in muscle. I. Effect of loading on fatigue.** OTTO RIESSER AND WALTER SCHNEIDER. *Arch. ges. Physiol.* (Pflüger's) 221, 713-9(1929).—To a high degree, fatigue is independent of the load and the mech. work. Fatigue is more strictly related to the rate of acid production than to the total amt. produced. II. **Formation of lactic and phosphoric acids in the isolated frog muscle with different degrees of isotonic activity.** T. NAGAYA. *Ibid* 720-32.—In the course of fatigue due to a rhythmic stimulus under anaerobic conditions the formation of acids is related to the period of stimulation or the number of stimuli, but is not a function of the work done. III. **Lactic acid formation in the free contracting frog heart.** T. NAGAYA. *Ibid* 733-41(1929).—Lactic acid formation cannot be detd. by the work done, but is rather a function of the changes in length of the muscle fibers of the heart. G. H. S.

**Physiology of the blood vessel.** A. A. TITAIKV. *Arch. ges. Physiol.* (Pflüger's) 221, 787-99(1929).—Temp. exerts a very considerable effect upon the contraction, rhythm and tonus of arteries. Curare in small doses exerts its effects on the arteries apparently through the central nervous system, causing vasoconstriction and increased number and extent of the contractions. Large doses exert the opposite effects. With frogs KCl and CaCl<sub>2</sub> solns. cause a reflex vasodilatation, but if the lumbo sacralis is sectioned or if large doses of curare are given, KCl leads to vasoconstriction. In this respect CaCl<sub>2</sub> is antagonistic to KCl. The effect of K ions depends upon the nature of the anions. G. H. SMITH

**Permeability of the surface layer of muscle fibers for potassium, and the effect of sucrose.** JOSEF MONAUNI. *Arch. ges. Physiol.* (Pflüger's) 221, 800-6(1929).—Apparently K does not penetrate through the cells but through the interstices. Sucrose does not exert any immediate effect, but after a period of 40 mins. the penetration of K is increased. G. H. SMITH

**A report of experiments indicating some new factors in respiration.** E. FIDLAR. *Univ. Toronto Studies, Physiol. series*, No. 98, 77 pp. (1928).—There is described a *respi-ratory app.* for frogs in which an attempt is made to control temperature, total pressure, oxygen partial pressure and humidity. Certain rhythms in respiratory quotient were noted, there being a lower quotient for the night periods than for day periods. This diurnal rhythm did not remain const. for more than 4 days at any one time. Averaged over several weeks, the respiratory quotients for night periods were found to be 0.02 less than for day periods, being of the same magnitude as has been shown for man. It is suggested that this phenomenon is of a fundamental nature in animal life, although it may not occur in a normal environment, but only under those unnatural conditions which have been necessary in measuring gaseous exchange. Evidence was obtained of the presence of an unknown gas or gases, assumed "nitrogen," not only as an excretion, but also as an absorption of the animal. The significance of the findings is discussed. H. G. SMITH

**Relation of the liver to fat metabolism. I. Effect of liver lack on fat combustion and the respiratory quotient.** D. R. DRURY AND PHILIP D. MCMASTER. *J. Exptl. Med.* 49, 765-78(1929).—Fat combustion is carried on adequately in rabbits deprived of the liver or brought into a condition of extreme liver insufficiency. Even 24 hrs. after hepatectomy fat combustion goes on as well as in the normal animal. Evidently the liver plays no essential part in the breaking down of fat. C. J. WEST

**Biometry of calcium, inorganic phosphorus, cholesterol and lipid phosphorus in the blood of rabbits. III. Influence of various types of light environment.** ALVIN R. HARNES. *J. Exptl. Med.* 49, 859-82(1929); cf. C. A. 23, 2473.—The Ca, inorg. P, cholesterol and lecithin in the blood of normal rabbits are influenced by 4 types of light environment. Animals exposed to the ultra-violet light for a brief period each day give results which are diametrical to those obtained for animals living in total darkness. The results obtained for animals exposed to the Cooper-Hewitt light and for those

living in the open lab. are somewhat similar but occupy a position between those of the dark and ultra-violet groups. Animals do not develop immediately the characteristic effects of a particular environmental condition but pass through a period of accommodation which varies somewhat with different environmental conditions. C. J. W.

**Relation of chromatin to hemoglobin and bilirubin.** HERMAN H. RIECKER. *J. Exptl. Med.* 49, 937-43(1929).—Attention is directed to the diversity of opinion among investigators regarding the site and manner of hemoglobin formation in the body and its relation to bile-pigment metabolism. It is probable that in forming new hypotheses on this subject the earlier work of A. B. Macallum on the relation of chromatin to hemoglobin formation has not received sufficient consideration. By means of microchem Fe stains of the bone marrow cells, it is shown that the Fe content of the hematoblast is increased during rapid hemoglobin production in simple anemia. This fact is compatible with the work of M., who believed that hemoglobin is derived from the chromatin of the hematoblast. It does not support the theory that hemoglobin is formed as a part of a circulating pigment. It is suggested that bilirubin is derived from the chromatin of body cells through the intermediary stages of the respiratory pigments, hemoglobin and cytochrome, from erythrocytes and other cells, resp. C. J. W.

**The ratio of urea nitrogen to total non-protein nitrogen in the blood in normal pregnancy.** W. DENIS, E. L. KING AND FRANCES BRIGGS. *Am. J. Obstet. and Gynecol.* 17, 386-91(1929).—In the normal pregnant woman there is usually a slight decrease in the blood non-protein N and a relatively large decrease in the urea N. There is a slight but gradual decrease in the ratio of urea N to non-protein N during the course of pregnancy, while postpartum there is an equally definite rise in the ratio. R. C. WILLSON

**Cholesterolemia in infants.** J. BAYLAC AND M. SENDRAIL. *Arch. méd. enfants* 31, 662-9(1928); *J. Am. Med. Assoc.* 92, 270.—The free cholesterol in the blood serum was detd. in 100 children from 1 month to 15 yrs. in age by the colorimetric Grigaut method, the av. being 1.49. The cholesterol content changes with the age, as low as 0.95 in the first months, rising gradually to 1.69 at 10-15 yrs. R. C. WILLSON

**The influence of the endocrine glands on the elimination of acetone bodies in the urine of dogs on normal diet and while fasting.** H. MIZOKAMI. *Folia endocrinol. japon.* 4, 296-330(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 47, 438.—Normal dogs eliminate a measurable amt. of acetone daily. On the first day of fasting the acetonuria is increased in contrast to the feeding period, reaches its max. on the second and third days and then recedes. During the feeding period administration of thyroid substance increases the acetone elimination, while thyroid extirpation decreases it. Repeated adrenaline injections increase the acetonuria; repeated insulin injections diminish it. The increase and decrease in the elimination of acetone bodies under the influence of the endocrine gland were greater in the fasting period than in the feeding period. R. C. WILLSON

**Globulin and albumin in serum and urine.** T. GEILL. *Bibliotek f. Laeger* 120, 612(1928); *J. Am. Med. Assoc.* 92, 96.—This preliminary report gives the results of investigations on the pptn. of serum proteins and urinary proteins by means of  $(\text{NH}_4)_2\text{SO}_4$  and the dependence of the process on NaCl concn., pH, protein concn. and temp., as well as the urinary constituents, particularly NaCl and urea. R. C. WILLSON

**A comparison of the amylase concentration in the saliva of infants and adults.** WALTER B. MAYER. *Bull. Johns Hopkins Hosp.* 44, 246-7(1929).—Infants, both normal and premature, can digest starch from birth. The amylase concn. increases with the age of the individual, but varies widely in adults (200-2850 units per g. saliva) R. C. WILLSON

**The influence of endocrine preparations on the basal metabolism in hyperthyreosis.**  
I. **The influence of suprarenal preparations.** T. HARA. Univ. Kyoto. *Folia endocrinol. japon.* 4, 401-32(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 47, 466.—When 0.6-0.8 g. of suprarenal prepn. (Parke, Davis) was given daily to hyperthyreotics, the basal metabolism decreased in 7 cases, decreased slightly in 3 cases and was unchanged in 5 cases. The influence of the endocrine prepn. is evident after 20 days, but reaches its max. after 40-60 days. R. C. WILLSON

**Physiological investigation of fetus. III. Supplementary research of enzymes in digestive organs: lipase in the stomach.** T. TACHIBANA. *Japan. J. Obstet. and Gynecol.* 11, 20-6(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 47, 94.—The stomach of the human fetus and newborn forms lipase which splits tributyrin. The enzyme can be detected in the fourth fetal month and increases with subsequent development. It is formed in the mucous membrane. R. C. WILLSON

**The menstrual cycle and calcium.** A. BOCK. *Monatsschr. Geburtsh. u. Gynakol.* 79, 9-16(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 47, 313.—During the time of men-

situation the blood Ca varies between 9.2 and 10 mg. %, the normal value being 9.65 mg. %. The slight change is atypical. There is a premenstrual increase in blood Ca.

R. C. WILLSON

**The influence of biliary acids on the creatine metabolism.** SHIGERU IKOMA. *Okayama-Igakkai-Zasshi* 40, 890-8(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 47, 87.—Addn. of cholic acid or desoxycholic acid to autolyzed muscle broth inhibits the formation of urea and creatine and increases the amt. of arginine.

R. C. WILLSON

## G—PATHOLOGY

H. GIDEON WELLS

**The sedimentation test in pulmonary tuberculosis.** H. A. CLEGG. *Tubercle* 10, 205-12(1929).—The normal sedimentation rate by the Zeckwir and Goodel method (2 cc. 3% Na citrate and 8 cc. of blood in a 15 cc. centrifuge tube being used) was 9.6 cc. of red cells at 1 hr. In normal cases the physiol. variation was slight. The rate in pulmonary tuberculosis is an accurate measure of the activity of the lesion. The test is more useful in prognosis than diagnosis. Normal sedimentation rates were found in some cases of active pulmonary tuberculosis.

H. J. CORPER

**Seasonal variations in body weight in pulmonary tuberculosis.** M. KESAVA PAI. *Tubercle* 10, 212-15(1929).—There is a general agreement of wt. curves in all parts of the world, apparent differences being due to the differences in climate of localities where observations are made. Extremes of heat and cold and dryness of the air cause a fall of wt., while the pleasant temp. like summer in colder countries and the cold season in the tropics produces a rise in wt. curve. Rains have no effect.

H. J. CORPER

**Co-relation of calcium metabolism, parathyroid function and chronic pulmonary tuberculosis.** II. PHILIP ELLMAN. *Tubercle* 10, 257-66(1929); cf. *C. A.* 22, 805.—The Ca content of the blood serum in pulmonary tuberculosis varies only within normal limits (9 to 12 mg. per 100 cc.). In cases responding favorably to treatment the Ca content can be increased, but only within normal max. limits. The administration of Ca or parathyroid must be continued over prolonged periods if Ca retention is to be promoted. A combination of parathyroid ext. with Ca lactate has proved as effective as any. Microscopical examn. of the parathyroid glands in cases of pulmonary tuberculosis shows signs of increased functional activity of the glands. Conclusion: There is a definite relationship between pulmonary tuberculosis on the one hand, and Ca metabolism and parathyroid function on the other.

H. J. CORPER

**Observations on the occurrence of non-specific agglutinins in tuberculosis.** ROBERT A. KILDUFF AND WM. W. HERSOHN. *Am. Rev. Tuberculosis* 19, 223-7(1929).—Nonspecific, heterologous agglutinins may be produced in tuberculosis for microorganisms of the typhoid group and, infrequently, for *B. proteus* X 19. There was no apparent relation between the presence or amt. of agglutinins and the character or clinical course of the tuberculous infection. The occurrence of agglutinins for microorganisms of the typhoid group is not per se conclusive evidence that they are nonspecific, or heterologous in origin, as, in a definite no. of such cases, the patient will be found to have had typhoid fever or to have received antityphoid vaccine. Heterologous agglutinin-production in pulmonary tuberculosis is of relatively infrequent occurrence and without apparent relation to the clinical course of the disease.

H. J. CORPER

**A note on the occurrence of positive Wassermann and precipitin reactions in pulmonary tuberculosis.** ROBERT A. KILDUFF AND WM. W. HERSOHN. *Am. Rev. Tuberculosis* 19, 228-9(1929).—During the course of a study of the incidence of nonspecific agglutinins in pulmonary tuberculosis, both precipitin and complement fixation tests for syphilis were applied to the sera in 200 cases of all stages of pulmonary tuberculosis. Neg. results were obtained in 191 of these, and in the majority of these reacting pos. this was proven to be due to the specificity of the reaction.

H. J. CORPER

**A clinical study of tuberculin fractions prepared from non-protein culture media.** FREDERICK EBERSON AND ERNEST WOLFF. *Am. Rev. Tuberculosis* 19, 327-49(1929).—In extension of earlier work (*C. A.* 19, 2979; 20, 2536) in which the inadequacy of old tuberculin was stressed and tuberculin fractions were prepd. from non-protein culture media, the authors present detailed analyses of different tuberculous and non-tuberculous groups and conclude that a tuberculin prepn. described as T. E. (alc.- and ether-insol.) gives better results than ordinary old tuberculin and is more selective as a clinical test material. Six weeks growth on a non-protein culture medium described by Gessard and Vaudremer (*Compt. rend. soc. biol.* 87, 1012(1922)) is evapd. to  $\frac{1}{10}$  vol. and 19 vols. of pure MeOH are added. To the filtrate contg. washings of MeOH derived from the alc-insol. fraction were added 4 vols. of pure Et<sub>2</sub>O and a second fraction sepd. by filtra-

tion. The ppt. was washed thoroughly with ether and the combined filtrates were evapd. virtually to dryness to yield a third fraction. The alc-insol. fraction represented 3.44% by wt. of the original tuberculin, the ether-insol. fraction 1.6% and the ether-sol. 0.86%. For clinical tests the fractions were dild. so that 1 cc. contained 1 mg. of tuberculin material.

H. J. CORPER

**Blood-serum calcium in the negro.** C. LYDON HARRELL. *Am. Rev. Tuberculosis* 19, 350-2(1929).—Forty-four negroes with no chest pathology gave an av. serum Ca of 10.93 g. per 100 cc. of blood, this being 0.43 g. higher than the normal blood Ca as given for the white individual which is 10.5 and H. attributes this to the greater amt. of exposure of the negro to the sun rays as well as the use of 3 forms of food rich in Ca, namely, cheese, cabbage and turnips. In the second group there were 41 cases suspicious of having definite tuberculosis. The blood Ca averaged 9.8 g. which is 1.13 g. lower than normal, indicating a hypocalcemia.

H. J. CORPER

**The relationship between blood sedimentation index and fibrin content in tuberculous individuals.** ESTHER M. GREISHEIMER, CHARLOTTE C. VAN WINKLE AND OLGA H. JOHNSON. *Am. Rev. Tuberculosis* 19, 559-66(1929).—A significant relationship was found between the fibrin content and sedimentation index in the groups studied as well as in the sexes. In both sexes a significant correlation existed between the fibrin content and the amt. of sedimentation detd. at 15 min. intervals up to a 1 hr. period.

H. J. CORPER

**The nitrogen content of the blood in sensitized animals.** Z. DINNERSTEIN AND S. GENES. *Z. ges. expil. Med.* 62, 248-58(1928).—D. and G. corroborate the work of Freund and Rupp (*C. A.* 18, 112) and Hashimoto and Pick (*C. A.* 8, 3466) that there are no changes in the total or rest N in sensitization in the blood of guinea pigs.

F. L. DUNN

**The changes in  $p_H$  of the blood and urine after eating in normal and peptic ulcer patients.** VITZ ZSIGMOND VON PINTER-KOVATS. *Z. ges. expil. Med.* 62, 634-8(1928).—The  $p_H$  of the blood was detd. by the method of Hollo-Weiss, and the urine, by the method of Michaelis, following a breakfast. The differences in  $p_H$  were greater in the normal group than in the ulcer group.

F. L. DUNN

**The metabolic disturbances by trypanosomiasis of white rats.** I. G. SCHEFF. *Magyar Orvosi Arch.* 30, 110-9(1929); cf. *C. A.* 23, 641.—The injury and death of the host are not caused by toxins but result as a consequence of disturbances of metabolic processes. The trypanosomes deprive the organism primarily of sugar. As long as the supply is satisfactory, the metabolism remains undisturbed. As soon, however, as the liver is injured, its reserves are exhausted and the transformation of fats and proteins into sugar is hampered, hypoglycemia develops.

G. H. VON FUCHS

**The oxygenation and acid-basic equilibrium of blood by the trypanosomiasis in white rats.** I. G. SCHEFF. *Magyar Orvosi Arch.* 30, 120-4(1929).—Both sugar and O consumption play a very important role in the metabolic disturbances of the host. Acidosis has rather a secondary significance, diminishing the resistance of the infected animal. As in other cases of symbiosis, one finds the host and the parasites struggling for foodstuffs indispensable to life.

G. H. VON FUCHS

**Clinical discussions of metabolic diseases. II. Uric acid and gout.** P. F. RICHTER. *Deut. med. Wochschr.* 55, 749(1929).—A review and discussion of the relation between uric acid and gout.

ARTHUR GROLLMAN

**Liver function test in chirurgic diseases. Evaluation of the levulose test.** HANS ACHELIS. *Klin. Wochschr.* 8, 641-4(1929).—The ingestion of 60 g. of levulose by hepatopathics leads regularly (90%) to a levulosemia and levulosuria. Levulosemia and levulosuria seldom (10%) occur in healthy individuals under the above conditions. This can, therefore, serve as a liver function test. The less characteristic results obtained previously (*Deut. Z. Chirurgie* 205, No. 3-6; 207, No. 1-4) were due to the fact that too much levulose was administered. One hundred or even 75 g. of levulose may produce levulosuria in a large no. of normal persons. This test is never of any value in nephritics.

MILTON HANKE

**The cholesterol content of the skin.** A. H. ROFFO. *Neoplasmes* 7, 344-52(1928).—The percentage of cholesterol in the dry material is greater in the skin of the face than in the skin of the abdomen although the subcutaneous fat tissue in both regions contains about the same percentage of cholesterol. The skin of the man contains a greater percentage of cholesterol than the skin of the woman. More neoplasms occur in the skin of the face than in the skin of other regions and more neoplasms of the face occur in men than in women. In 1557 cases of neoplasms of the skin of the face examd., 70.9% were in men and 29.1% in women. Neoplasms contain a greater percentage of cholesterol

than normal tissues and it is probable that cholesterol is of importance in the establishment of a precancerous condition.

HARRIET F. HOLMES

**The effect of oxygen and carbon dioxide inhalation of short duration on the red blood picture of man under normal and pathologic conditions.** F. KERTI AND F. STENGEL. *Wien. Arch. inn. Med.* 16, 381-98(1929).—In 45 cases, both normal and pathological, the blood was examd. before and after the inhalation of  $O_2$ . In 21 of the 45 cases there was a distinct change in the erythrocyte count, a decrease in 16 and an increase in 5 cases. Most cases showing a decrease had a relatively high initial erythrocyte count. Hemoglobin only seldom showed change and the size of the erythrocytes was altered only in a few cases. The most marked changes in no. and size were in cases of polycythemia. After  $CO_2$  inhalation there was almost always a fall in blood pressure and a deepening of respiration while both the pulse rate and the respiration rate varied. There was a definite change in erythrocyte count, an increase in normal cases and in pernicious anemia and a decrease in polycythemia. The size of the erythrocytes was little affected, except in a case of polycythemia in which there was a decrease, and in a case of pernicious anemia in which there was a marked increase. HARRIET F. HOLMES

**Fractionation and antigenetic properties of diphtheria toxin.** P. SEDALLIAN, A. LEULIER AND MME. CLAVEL. *Compt. rend.* 187, 1297-9(1928).—Diphtheria toxin adjusted to a pH of 4.7 seps. into 2 fractions. The sol. portion consists of protein material and pigments and is non-toxic as shown by injections made on guinea pigs. The pptd. fraction dissolved in saline soln. is toxic but not so toxic as the original toxin. The addn. of a peptone increases the toxic power of the pptd. fraction until the lethal dose is about the same as that for the unaltered toxin. The existence of non-specific colloids in toxins that increase the absorbent power of the specific toxin and thereby its toxicity is discussed.

J. G. McNALLY

**The sulfur content in the blood serum of syphilitics.** SILVIO COLOMBINO. *Biochim. terap. sper.* 16, 5-8(1929).—The blood serum of 32 cases of syphilis showed a noticeable increase in total S, protein S and non-protein org. S. This increase was noted in all stages of the disease, even in the pre-humoral period. The ratio non-protein org. S:inorg. S was considerably higher than the normal.

PETER MASUCCI

**The serum-chromogen reaction in syphilis.** ENRICO DE-SILVESTRI. *Biochim. terap. sper.* 16, 59-61(1929).—Certain specific substances X are present in the serum of syphilitics which react with certain reagents ( $H_2SO_4$ , citric acid, monochloroacetic acid and vanillin) to give characteristic color tests. The substances X are probably antigen-antibody combinations. The reaction is very sensitive and is very useful in the diagnosis of syphilis. For the prepn. of the reagents and the details of the technic of the test, consult the original.

PETER MASUCCI

**The physical-chemical constants of the blood in eclampsia.** I. OSCAR M. BERNARDI. *Boll. soc. ital. biol. sper.* 4, 77-9(1929).—The av. lowering of the f. p. ( $\Delta$ ) of 16 detns. on 8 normal non-pregnant women was  $-0.553$ . The av.  $\Delta$  of 24 detns. on 12 normal but pregnant (9 months) women was  $-0.541$ . The av.  $\Delta$  of 31 detns. in 8 eclampsia cases was  $-0.5727$ . The elec. conductivities of defibrinated blood and blood serum were detd. Conclusion: The defibrinated blood and blood serum of eclampsia cases show a diminution of elec. cond. with respect to the blood of pregnant women.

II. Viscosity. *Ibid* 80-2.—The av. viscosity of 24 detns. on the defibrinated blood of 8 normal non-pregnant women was  $\eta = 4.3$ . The viscosity of the defibrinated blood of normal pregnant women was  $\eta = 4.1$  (av. of 24 detns. on 8 women). The viscosity of the defibrinated blood of 13 eclampsia cases varied from  $\eta = 5.31$  to  $\eta = 10.70$ . The higher figures were obtained on the bloods drawn immediately after a convulsive attack.

PETER MASUCCI

**Study of the physico-chemical properties of tissues in relation to the normal and pathological conditions of the organism. IV. Experimental modifications of the receptivity of mice for cancer grafts.** F. VLÈS AND A. DE COULON. *Arch. phys. biol.* 6, 22-37(1927); cf. C. A. 21, 3671.—Many substances, as emery, kaolin, silica, powd. metals, org. substances, lower the receptivity of mice for cancer graft. The index of receptivity as a function of the time elapsed between interference and graft has been studied. The index is expressed by  $i = (S-T)/T$ , S being the proportion of graft, taking in animals treated, to the proportion of controls. The chem. property of the substances has no influence.

A. E. MEYER

**Displacement of the isoelectric points of serum in acute infections.** PAUL H. ROSSER. *Arch. phys. biol.* 6, 129-38(1927); *Physiol. Abstracts* 13, 329.—In acute infectious diseases, a shift of the isoelec. point of the serum is observed. Beginning with incubation, the isoelec. points are displaced toward higher pH, attaining a max. after

the decline of the fever. The return to normal shows a curve with oscillations and a neg. phase, where the isoelec. point descends to  $pH$  5.5. A. E. MEYER

The role of the thyroid and parathyroid gland in adrenaline hyperthermy and in salt fever. G. VIALE AND J. KURI. *Rev. sud-americana endocrinol.-immunol., quimioterap.* 11, 831-9(1928).—Adrenaline hyperthermy and salt fever depend on the cooperation of the thyroids; the parathyroids have the more important role. The absence of hyperthermy in animals after parathyroidectomy is related to the lower Ca content of the blood. A. E. MEYER

Effect of cations on the fermentative ability of the tumor cell. I. A. LASNITZKI AND O. ROSENTHAL. *Biochem. Z.* 207, 120-40(1929).—In Ringer soln. lacking either the K or Ca ions the fermentation produced by tumor cells is diminished. In the Flexner-Jobling rat carcinoma the av. reduction is over 40% and in Jensen's rat sarcoma, about 25%. S. MORGULIS

Chemical studies on the "Haff disease." A contribution to the arsenic hypothesis. GEORG LOCKEMANN. *Biochem. Z.* 207, 194-216(1929).—Neither in the air above the water surface nor in the gases developed from As-contg. slime or algae of the "Frische Haff" could even traces of arsine be discovered, which is also true of the water itself. These observations were made at the time when the "Haff disease" epidemic was still raging. Evidence of As present in these materials reported by other investigators is attributed to impurities of reagents. The putrefactive gases evolved in the "Haff" have been found to be entirely innocuous for animals. Likewise various water animals obtained in the "Haff" region show only traces of As, which holds true for the aquatic plants except the algae. These investigations definitely disprove any relation of As to the epidemic outbreak of the "Haff disease." S. MORGULIS

Liver and thyroid: hyperfunction of the liver in Basedow's disease. N. PENDE. *Endokrinologie* 1, 161-7(1928). S. MORGULIS

New studies on the diagnosis, pathology and therapy of Basedow's disease and hyperthyreoses. KARL CSÉPAI. *Endokrinologie* 1, 250-63(1928).—In patients with Basedow's disease an increased sensitivity to various hormones was noted. The hormones studied were adrenaline, pituitrin, insulin, parathormone and thyroxine. Thyroxine also increases the responsiveness to the other hormones. The combined iodine and x-ray therapy gave very good results, further progress in this direction depends upon the success in finding the best way of detg. the dosage. S. MORGULIS

The antigenic properties of the d'Herelle bacteriophage. A. K. HORST. *Centr. Bakt. Parasitenk.*, I Abt., 111, 1-8(1929).—Antibacteriophage serum contains something which exerts a definite inhibition of the homologous bacteriophage. JOHN T. MYERS

The biological differences between heated and unheated water-soluble antigens of the cholera vibrio. I. The differences in the production of agglutinins and precipitins. K. FUJIMORI. *Centr. Bakt. Parasitenk.*, I Abt., 111, 68-83(1929).—Antibody production by heat-killed cholera cells = that by killed cells + unheated broth filtrate, <unheated cells + bouillon < unheated cells + filtrate heated for 20 mins. in a boiling water bath. Heating the filtrate in this manner increases its antigenic power. It is suggested that filtrate contains a thermolabile substance which interferes with the action of antigenic substances, the latter being thermostable. JOHN T. MYERS

The isolation of an active protein from anthrax-precipitating serum. H. P. ROSENHOLZ. *Centr. Bakt. Parasitenk.*, I Abt., 111, 92-5(1929).—A globulin was obtained from anthrax-pptg. serum equal in titer to the whole serum. The serum was dild. with 5 or 6 vols. of distd. water, the resulting ppt. removed by double paper filtration or centrifugation, and dried at 37°. The yield was 0.6 to 1.0 g. per 100 cc. of serum. This product is insol. in distd. water but sol. in the presence of electrolytes or weak alkalies. When dissolved in a minimal amt. of 3% NaCl soln. and filtered through paper, a clear, somewhat opalescent fluid resulted. The dried pptd. globulin is stable and easily transportable and should be of practicable value. JOHN T. MYERS

The work of Regendanz and Tropp on trypanosomiasis. KURT SCHERN. *Centr. Bakt. Parasitenk.*, I Abt., 111, 139-43(1929).—The pathogenesis of trypanosomiasis and spirachetosis depends largely on disturbances in carbohydrate metabolism. J. T. M.

Studies on the existence of neurocidins as described by Aldershoff and Pondman. E. GILDEMEISTER AND GEORG HEUER. *Centr. Bakt. Parasitenk.*, I Abt., 111, 151-6(1929).—Injections of brain emulsions did not produce neurocidins in the sense of Aldershoff and Pondman. Lysis was apparently due to particles of glass since none occurred if the containers were lined with paraffin. JOHN T. MYERS

The leucocyte phenomenon in lobar pneumonia in a physicochemical light. K. RUDSIT. *Folia Haematol.* 37, 377-87(1929).—When 2 cc. of a 20% soln. of  $CaCl_2$  is injected intravenously, there is a rise in the leucocyte count within 2 to 5 mins. in nor

mal individuals. In cases of lobar pneumonia there is a drop instead of a rise. The usual rise follows such an injection 3 days after the temp. crisis. More work is promised.

JOHN T. MYERS

Review of the physical and chemical hematological contributions in the field of pediatrics for the year 1926. OPITZ. *Folia Haematol.* 37, 404-18(1929).—The article is a review and an extensive bibliography.

JOHN T. MYERS

Tumor immunity. Natural cytotoxins (heterotoxins); protection of cells against homologous antibodies. THOMAS LUMSDEN AND ALICE C. KOHNSPEYER. *J. Path. Bact.* 32, 185-93(1929).—The fresh serum of normal animals contains a non-sp. cytotoxin against tumor cells and the normal tissue cells of foreign animals. They are of the nature of very labile immune bodies and are ineffective in the absence of complement. Tumor cells possess some mechanism which protects them specifically against damage by homologous cytotoxin, either sp. or non-sp.

JOHN T. MYERS

The content of complement compounds in dialyzed guinea-pig serum. H. TOKUNAGA. *Acta Schol. Med. Univ. Imp. Kioto* 11, 273-86(1928); cf. *C. A.* 22, 3217.—When serum is dialyzed for 5 to 9 hrs., the globulin fraction in physiol. NaCl soln. possesses complementary activity. The complementary effect of the globulin fraction first increases with increasing duration of dialysis and then decreases; after a dialysis of 24 hrs., the complementary effect is no longer present. In isotonic AcOK soln., however, the globulin fraction is able to hemolyze completely strongly sensitized goat erythrocytes. In this case the hemolytic action increases with the duration of dialysis. An almost complete hemolysis may be produced by the globulin fraction after dialysis for 24 to 48 hrs. A decrease in the activity of the albumin fraction occurs progressively with the duration of dialysis; finally it is completely inactivated (after 48 hrs.). Thus with increasing duration of dialysis the complement activity passes into the globulin fraction. An inhibitory influence on the effect of complement was observed during the dialysis, the inhibition being more distinct in physiol. NaCl soln. than in AcOK soln. Hence it may be assumed that complement is not split into 2 compds. In the course of dialysis the principle reactivating serum that has been inactivated with  $(\text{NH}_4)_2\text{SO}_4$  accumulates in the globulin fraction. However, the albumin fraction, in which no complementary effect can be detected, is still able to reactivate completely the serum treated with  $(\text{NH}_4)_2\text{SO}_4$ .

G. SCHWOCH

The content of complement compounds in the fractions obtained by precipitation with ammonium sulfate. H. TOKUNAGA. *Acta Schol. Med. Univ. Imp. Kioto* 11, 287-96(1928); cf. preceding abstr.—The complement of guinea-pig serum is fractionated by addn. of  $(\text{NH}_4)_2\text{SO}_4$ , the quant. distribution depending on the amt. of  $(\text{NH}_4)_2\text{SO}_4$  employed. The complement passes into the globulin fraction. The effect is more pronounced if the globulin fraction is taken up in AcOK soln., because in physiol. NaCl soln. a certain inhibition of the complementary activity occurs. On half-satn. with  $(\text{NH}_4)_2\text{SO}_4$ , the globulin fraction shows the complementary effect almost quant. Accordingly a decrease in the effect of the 2nd fraction occurs. After half-satn. the 2nd fraction is no longer able to act as complement. The complement in the fractions reacts more slowly than that of the original active serum. By satn. with  $(\text{NH}_4)_2\text{SO}_4$  the entire complement goes into the ppt., the latter showing a nearly complete complementary activity. A mixt. of the 2 fractions exerts an action just as great as that of the original active serum. The results of Browning and Mackie and those of T. described in earlier papers, according to which it seemed possible to split complement with  $(\text{NH}_4)_2\text{SO}_4$ , are erroneous and probably due to faulty exptl. technic.

G. SCHWOCH

The content of complement compounds in guinea-pig serum fractionated by passing carbon dioxide through it. H. TOKUNAGA. *Acta Schol. Med. Univ. Imp. Kioto* 11, 297-312(1928); cf. preceding abstr.—Both the globulin and the albumin fractions obtained by passing  $\text{CO}_2$  through guinea-pig serum at low temp. are able to act as complement when taken up in isotonic AcOK soln. The complementary activity of the globulin fraction increases only to a slight degree on passing  $\text{CO}_2$  through the serum for a long period of time. The albumin fraction obtained at low temp. possesses a strong complementary activity, which, however, is decidedly inhibited by an excess of the albumin fraction. This inhibition is more pronounced at elevated temp. The complementary activity disappears in both the albumin and the globulin fractions when the  $\text{CO}_2$  is passed through the serum at elevated temp. However, in conjunction with each other, the 2 resulting fractions produce a distinct hemolysis. The power of reactivating the serum previously inactivated with  $(\text{NH}_4)_2\text{SO}_4$  disappears almost entirely in the globulin fraction, when the  $\text{CO}_2$  is introduced at elevated temp. The reactivating properties of the albumin fraction do not suffer any loss. The complementary activity in the globulin and albumin fractions lost by passing  $\text{CO}_2$  at elevated temp. through the serum

may be restored by addn. of a small quantity of active guinea-pig serum or by addn. of serum heated at 56° and deprived of its euglobulin by proper treatment with CO<sub>2</sub>. The complete splitting of complement into 2 compds., which only occurs at elevated temp. and at an optimum diln., is only apparent, because the part of the complement necessary for the reactivation of the (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> serum is greatly damaged in the globulin fraction while it remains almost undamaged in the albumin fraction.

G. SCHWOCH

**The action of alcohol on the complement of guinea-pig serum.** H. TOKUNAGA *Acta Schol. Med. Univ. Imp. Kioto* 11, 313-7(1928); cf. preceding abstr.—The ppt obtained by action of EtOH on guinea-pig serum and taken up in physiol. NaCl soln. cannot produce complementary activity. In isotonic AcOK soln., however, it acts as a complement, though to a slight extent only; its activity decreases with the duration of the treatment with EtOH. The EtOH ppt. exerts little or no reactivating action on guinea-pig serum inactivated with (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>.

G. SCHWOCH

**Specific antivenins to combat scorpionism and arachnidism.** AFRANIO DO AMARAL *Bull. Antivenin Inst. America* 2, 69-71(1928).—By application of the principles of immunization used in the production of antitoxic sera, therapeutically effective antisera can be produced for the poisons of scorpions and spiders. Since scorpion venoms are sp. appropriate antisera must be used in treatment. In South America, since an antiserum has been available for the poison of the common variety, *Tityus bahiensis*, no deaths from scorpionism have been reported. The 2 species of spider responsible for most cases of arachnidism are *Lycosa raptoria* and *Ctenus nigriventer*, and their poisons are highly sp. *Lycosa* poison causes a local necrosis, but no systemic action; *Ctenus* venom causes intense pain, a slowed pulse, reduced temp., muscular contraction, convulsions and anuria. The bivalent antivenin is therapeutically effective.

G. H. SMITH

**The cold-hemagglutinin.** N. YU. *Acta Med. Keijo* 11, 23-34(1928).—The hemagglutinin which reacts strongly at 0° and which is non-active at 37° has been called by Shiga cold-agglutinin. Normal rabbit serum contains the auto-cold-hemoagglutinin. Normal horse serum contains but little auto-cold hemagglutinin. The cold-agglutinin as well as the auto- and hetero-agglutinin is not harmed by heating for 30 min. at 60°. At 65° they are slightly injured and at 70° they are entirely destroyed. The receptors for the cold-agglutinin and the immuno-agglutinin are specific and differ from one another. The receptors of the auto- and hetero-cold agglutinin are strongly specific.

ARTHUR J. VORWALD

**Experimental dehydration: Chemical changes in the blood of the dog contrasted with those following obstruction of the cardiac end of the stomach.** RUSSELL L. HADEN AND THOMAS G. ORR. *J. Exptl. Med.* 49, 945-53(1929).—A comparative chem. study of the blood and the urine of the dog with exptl. dehydration and with obstruction of the cardiac end of the stomach is reported. The av. duration of life is slightly longer with dehydration than with obstruction. The urine output per kg. of body wt. is almost twice as great in dehydration as with obstruction. The increase in non-protein N and urea N is much the same in the 2 groups although somewhat more marked with obstruction. The chlorides of the blood are markedly increased with dehydration and slightly decreased with obstruction. The increase in fibrinogen and total protein is twice as great with obstruction as with dehydration. These findings indicate that there must be some factor or factors in addn. to dehydration producing the toxemia of cardiac obstruction.

C. J. WEST

**Chemical findings in the blood of the dog after closed-loop obstruction of the jejunum.** RUSSELL L. HADEN AND THOMAS G. ORR. *J. Exptl. Med.* 49, 955-8(1929).—The chem. findings in the blood of 6 dogs with closed-loop obstruction of the upper jejunum are reported. The duration of life with closed loops is less than with simple obstruction. All animals showed a marked rise in non-protein N and urea N and fall in chlorides. Usually the CO<sub>2</sub>-combining power of the plasma is increased. The findings in closed-loop obstruction are essentially the same as those in simple intestinal obstruction.

C. J. WEST

**The inactivation of the chicken-tumor virus by means of calcium compounds.** MARGARET REED LEWIS AND HOWARD B. ANDERVONT. *Bull. Johns Hopkins Hosp.* 42, 191-7(1928).—The addn. of CaO, Ca mono-basic phosphate and Ca hexosephosphate in as small quantities as 0.5, 0.75 and 1%, resp., to the chicken-tumor ext. (1:10) inactivated the virus and prevented the growth of a tumor. Larger amts. (25%) of CaCO<sub>3</sub> adsorbed and fixed the virus. The addn. of 2% plaster of Paris inactivated the virus, but 1% was ineffective.

## H—PHARMACOLOGY

A. N. RICHARDS

**Studies on the mechanism of the fluoride effect.** F. LIPMANN. Kaiser-Wilhelm Inst. Biologie, Berlin-Dahlem. *Biochem. Z.* 196, 3-21(1928).—The effect of F on the hydrolysis of  $H_2PO_4$  from esters and on the respiration and lactic acid production of muscle has been investigated. The hydrolysis of glycerophosphoric acid, hexosediphosphoric acid and hexosemonophosphoric acid by muscle pulp, by coenzyme-free acetone yeast, or by muscle ext. is only slightly less inhibited by F than is the lactic acid production. Conclusion: The inhibition of lactic acid production is due to the depression of  $H_2PO_4$  hydrolysis. The respiration of cut muscle is influenced less than the lactic acid production by the F, its repression being detd. *indirectly* by the inhibition through the diminution of lactic acid concn. which can be remedied by the addn. of lactate; and *directly* by the inhibition of respiration. The opposite effect of respiration and lactic acid production becomes particularly marked under the addn. of lactate, when 0.01 N NaF inhibits the latter 100% while it has no effect at all on the former. These expts. also demonstrate the important fact that the extent of respiration in NaF depends upon the lactic acid concn. The oxidation quotient of lactic acid is much reduced by F, and is only 1 when lactic acid production is inhibited, *i. e.*, there is no resynthesis of lactic acid. The oxidation of glycerophosphoric acid is practically not influenced by F, whereas the hydrolysis of  $H_2PO_4$  is already suppressed, which is the reverse of the condition under the influence of HCN.

**Clinical tests of the practical value of the new sexual hormone preparations.** RUD. TH. V. JASCHKE. *Deut. med. Wochschr.* 55, 301-2(1929).—The sexual hormones are useful in cases of secondary amenorrhea, hypoplasia of the uterus, premature climacterium and after ovariectomy.

ARTHUR GROLMAN

**The mechanism of pilocarpine hyperglucemia.** GAETANO VIALE AND LUIGI NAPOLEONI. *Biochim. terap. sper.* 15, 421-4(1928).—The suprarenals were removed from 5 dogs and the animals were injected intravenously with one cg. of pilocarpine. In dogs without suprarenals, pilocarpine either fails to effect the glucemia, or else produces a profound hypoglucemia, comparable in intensity to that of insulin. Therefore, the suprarenals are involved in pilocarpine hyperglucemia in the sense that under the action of this alkaloid, adrenaline is set free. Probably, in itself, pilocarpine has a hypoglucemic action similar to that of choline. This hypothesis explains Bucciardi's results who found that in guinea pigs, pilocarpine in small doses did not modify the glucemia, in medium doses produced hyperglucemia, and in large doses produced no effect. The last results indicate that the hypoglucemic action of pilocarpine neutralized the hyperglucemic action of adrenaline. Similarly, this mechanism also explains why ergotamine impedes the hyperglucemic action of pilocarpine, and why pilocarpine produces hypoglucemia if injected after ergotamine.

**Action of bromine on the fat bodies of insects.** JEAN TIMON-DAVID. *Compt. rend.* 188, 1122-4(1929); cf. C. A. 22, 4178.—Continuing his work on insect fats T.-D.

detd. the I no. (Wijs) of the fats of numerous insects: *Vanessa urticae* L. 159.7, *Pieris brassicae* L. 149.9, *Saturnia pernyi* Guer. 140.4, *Archia caja* L. 133.3, *Malacosoma francica* Esp. 138, *Colaspidea atra* L. (larva) 113.4, *Leptinotarsa decemlineata* Say (imago) 108.6, and *Galerucella luteola* Mull 118.2. The hexabromide no. (Hehner) was also made on several insect oils: *Saturnia pernyi* Guer. 14.7, *Pieris brassicae* L. 14.3, *Thaumetopoea pityocampa* Sch. 2.1, *Leptinotarsa decemlineata* Say 3.1, *Colaspidea atra* Oliv. 6.3, and *Ergates faber* L. 0.0. *Linolenic acid* was identified in the oil derived from *Colaspidea atra* Oliv. The food of insects plays an important role in the compn. of their body fat. C. R. FELLERS

Further studies on the silver line system of ciliata. BRUNO M. KLEIN. *Arch. Protistenk.* 65, 183-257(1929); cf. *C. A.* 22, 4563.—The occurrence of specific line systems (formed after Ag staining) is described for the conjugation period of *Colpodium campylum*, *C. copoda*, *Euplotes* and *Aspidisca*. Good bibliography. F. K.

The different seat of action of the calcium ion and of the potassium ion on the spinal medulla of *Bufo vulgaris*. MICHELE MIROLO. *Boll. soc. ital. biol. sper.* 4, 39-41 (1929).—The central seat of action of the Ca and K ions was investigated. Baglioni's prepn. was used; the KCl and CaCl<sub>2</sub> solns. were applied on the posterior intumescence of the isolated spinal medulla of *Bufo vulgaris* and the variations in the excitability of reflex were noted. Solns. of 0.1-0.88% KCl produced no effect when applied on the dorsal surface of the posterior intumescence, but did provoke a diminution of the reflex activity of the prepn. if applied on the ventral side. On the contrary, CaCl<sub>2</sub> solns. in concns. up to 4% when applied on the ventral side did not provoke any appreciable alterations of the excitability, but if applied on the dorsal side of the same intumescence, solns. as weak as 1.17% produced diminution of the reflex activity, which became more accentuated with 2.4-4.0% solns. until the excitability disappeared. Conclusion: The K and Ca ions are both depressor poisons of the central nervous system. They have, however, a different seat of action: while the K ion causes depression by acting on the motor centers mechanism of the anterior horn, the Ca ion depresses the central activity by acting on the sensori-coördinators of the posterior horn of the spinal medulla.

PETER MASUCCI

Potentiometric study of the oxidation-reduction potential of the eggs of the sea urchin. EDMOND VELLINGER. *Arch. phys. biol.* 6, 141-51(1927); cf. *C. A.* 22, 463.—The detn. of the  $p_H$  was performed after grinding the eggs at  $-60^\circ$  at a temp. near the cryoscopic point. The interior  $p_H$  is for *Arbacia aequituberculata* 5.2, for *Paracentrotus lividus* 5.8. The  $p_H$  obtained by the direct method is slightly higher than that obtained by the use of indicators. A. E. MEYER

Function of the interrenal tissue in the torpedo. BRUNO KISCH. *Endokrinologie* 1, 31-9(1928).—Total extirpation of the interrenal tissue in torpedoes leads, after a latent period of one to several days' duration, to a no. of typical symptoms. The pigment of the skin chromatophores is clumped together tightly, a condition which persists until death and gives the animals a dirty gray color. The respiration is generally strongly inhibited and body movement causes further slowing up and deepening of the respiration. The animals show progressive weakening of the muscles, quick fatigue and an inertia which may actually lead to failure to respond to stimulation. Furthermore, rigidity and contracture of the muscle occur, lasting till death and causing extreme conditions of opisthotonus. Following interrenal tissue extirpation the animals become extraordinarily sensitive to lack of O<sub>2</sub>. Survival of the extirpation depends upon the special and individual constitution (age, pregnancy, etc.), temp., O<sub>2</sub> supply, while intense body movement may induce sudden death. Death is due to respiratory arrest, while the heart still beats regularly. It is believed that the interrenal tissue yields to the blood some compd. which is directly or indirectly responsible for the oxidation of certain metabolic products. S. MORGULIS

Studies on the chemical embryology of reptiles. I. MASAJI TOMITA. *J. Biochem.* (Japan) 10, 351-6(1929).—The eggs of the sea turtle, *Chelonia cauwana*, have an av. wt. of 34.4 g., of which the shell weighs 2 g.; the white, 13.5 g. and the yolk, 18.9 g. 13.5 g. of the egg white is composed of 13.30 g. water and 0.2 g. dry residue; it contains 0.04 g. N and 0.08 g. ash. The 18.9 g. yolk consists of 13.75 g. water and 5.15 g. dry residue, with 0.55 g. N and 0.22 g. ash. The 2 together contain 1.65 g. fat and 2.81 N-free extractives. The egg white contains very little free amino acids, no tryptophan and no purine bases. In the egg yolk the amino acid content is much greater and the same as in chick egg yolk. Tryptophan is also present. In the course of development the urea of the egg content increases gradually from 0.0056% in the fresh egg to 0.0294% after 30 days and to 0.0612% after 45 days of incubation. The uric acid content which in the fresh egg is nil rises to 0.17 mg. after 15 days' incubation but does not increase

beyond that even after 45 days. **II. The behavior of the non-protein nitrogen of the reptilian egg during incubation.** MASAJI TOMITA AND YASUO NAKAMURA. *Ibid* 357-60.—The entire egg of the sea turtle contains 1.77% total N which is much less than that in the hen egg, and this total diminishes during incubation, falling to 1.54% at the end of 45 days. The non-protein N, however, increases during incubation. The fraction precipitable by phosphotungstic acid is very small as compared to the hen egg. **III. The production of *d*-lactic acid in the incubation of the sea turtle egg.** MASAJI TOMITA AND YUZO SENDJU. *Ibid* 361-3.—The amt. of *d*-lactic acid in the fresh sea turtle egg is 0.008% and increases to 0.041% after 15 days of incubation, which is very much less than in the developing hen egg. The lactic acid content then remains about the same throughout the later stages of incubation (0.015%). **IV. The behavior of the essential amino acids in the incubation of the sea turtle egg.** *Ibid* 365-7.—The various essential amino acids are found in quantities  $\frac{1}{2}$  to  $\frac{1}{4}$  that present in the hen egg. During incubation the content of tryptophan, tyrosine, cystine and arginine gradually increases. The quantity of lysine remains practically unchanged. There is a gradual rise in the histidine content which is not the case in the developing hen egg. The purine bases, both free and combined, increase with the progress of the development of the embryo. **V. Relation of inorganic components to the incubation of sea turtle eggs.** MASAJI TOMITA AND JUNJI KARASHIMA. *Ibid* 369-74.—The only striking alterations in the mineral compn. are the great increase in Ca, Mg and P found in the advanced stage of incubation and in the newly hatched embryo, which indicate that the shell is used up in the developmental process. The P increase is at the expense of org. P which begins to disappear in the last third of the incubation period. **VI. The behavior of fat in the incubation of the sea turtle egg.** *Ibid* 375-7.—The total fat content of the whole egg diminishes considerably in the last developmental stages. After the 15th day of incubation there is a marked rise in the free fatty acids. These free acids cannot be due to the oxidation of non-fat components of the egg since the total amt. is not changed thereby. **VII. The enzymes in the sea turtle egg.** MASAJI TOMITA AND JUN-ICHIRO SAGARA. *Ibid* 379-82.—Diastase, lapase and nuclease increase during incubation, especially in the late stages and in the newly hatched embryo. The trypsin activity remains unchanged in the egg but shows an increase in the newly hatched embryo.

## 12—FOODS

F. C. BLANCK AND H. A. LEPPER

**Definitions and standards for food products.** Food, Drug and Insecticide Administration, U. S. Dept. Agr. *Service & Regulatory Announcement* F. D. No. 2 (Rev. 1), 20 pp.(Dec., 1928).—The principles on which definitions and standards are based are set forth and those adopted for guidance of officials in the enforcement of the food and drugs act: meats and the principal meat products, milk and milk products, grain products, fruits and vegetables, sugars and related substances, condiments (other than wines, vinegars and salt), tea, coffee and cacao products, beverages, wines, vinegar, salt and baking powder.

H. A. LEPPER

**Regulations for the enforcement of the Federal Food & Drugs Act.** Food, Drug and Insecticide Administration, U. S. Dept. Agr. *Service & Regulatory Announcement* F. D. No. 1, 19 pp.(Oct., 1927).—The text of "An act for preventing the manufacture, sale, or transportation of adulterated or misbranded or poisonous or deleterious foods, drugs, medicines and liquors and for regulatory traffic therein, and for other purposes" as amended is given with the regulations adopted.

H. A. LEPPER

**The relation of research to control.** C. A. BROWNE. *J. Assoc. Official Agr. Chem.* 12, 211-23(1929).—An address dealing principally with the development of the application of research to food and drug control in the U. S.

A. P. C.

**Certification of coal-tar colors.** Food, Drug and Insecticide Administration, U. S. Dept. Agr. *Service & Regulatory Announcement* F. D. No. 3, 10 pp.(Oct., 1927).—The procedure for the certification of coal-tar food colors is outlined and the requirements which such dyes must meet are given. The permitted dyes, 14 in no., are listed in Supp. No. 1 issued April, 1929.

H. A. LEPPER

**Solbrol [methyl *p*-hydroxybenzoate].** U. G. BILSMA. *Arch. intern. Pharmacodynamie* 34, 173-9(1928); *Physiol. Abstracts* 13, 476.—The preventive action of solbrol on the growth of bacteria and molds is of the same order as that of salicylic acid, and similar effects are produced by equal quantities. Solbrol is only slightly toxic, and its use in the preservation of food is without danger. No ill effects on health have been observed, but it is not advisable to use large quantities. The continuous use of either drug causes a lowering of resistance of young rats in unfavorable outward conditions, but when these are not bad it is well borne in doses of 4 g. per kg. per day. The effect of solbrol on N exchange of dogs is appreciably less than that of salicylic acid. On decompn. in the body 250 mg. of solbrol yields 54 mg. of MeOH, which causes no trouble.

H. I. D.

**The effect of boiling on the nutritive value of food.** NATALIE YARUSOVA. *Biochem. Z.* 207, 395-404(1929).—Prolonged boiling has no appreciable influence on the nutritive value of food.

S. MORGULIS

**Interim report on protein content as a factor in grading wheat.** H. M. TORY, et al. Natl. Research Council (Canada) *Bull.* 13, 7-60(1929).—Interviews were made in various parts of the U. S. on the advisability of making protein content a factor in grading wheat. Modern bakeries require a flour with a protein content of 10.75 to 11% and are willing to pay a premium for high protein flour. The cost in 5 labs in the U. S. for making a single protein test was not over \$0.50. If protein tests were required on all wheat, sampling would need to be done more carefully, and extra bin space would be required at the elevators. It would probably not affect greatly the speed of movement of the crop. In the U. S. protein content is not a grade factor but the premiums paid for high protein content make it the prime factor in detg the price of high-protein wheat. If it were a factor in grading wheat in Canada and the premium received for high protein could be reflected to the growers, more high protein wheat would be grown. Certain European buyers test samples of wheat for strength before buying, and Canadian wheat often receives a premium because of its high av. protein content. In countries where there is no standard system of baking, however, high-protein wheat is not valued, and it is a question if the demand for high-protein and the premiums received will pay for the extra cost of the tests and of keeping the wheat sep. in exporting. A study of drying moist wheat showed that 82° is the max. safe temp. for the drying air, and that the initial H<sub>2</sub>O content did not affect the quality of the dried grain. The establishment of an exptl. mill at Winnipeg is suggested as a means of checking lab. results on a semi-com. scale.

AMY LÉVESCONTE

**New method of determination of Indian corn flour admixed to wheat flour.** A. V. MILSKIL. *Ukrainskii Khim. Zhur.* 3, *Tech. pt.*, 183-208(1928).—Air-dry the flour which is to be analyzed, place 37.5 g. in a 250-cc. volumetric flask, add 150 cc. 95%

EtOH, shake the contents to mix well, adapt a reflux condenser and reflux the mixt. exactly 1 hr. on a water bath. The strength of the EtOH used must be exactly 95% as detd. by a Tralles alcoholometer, as the quantity of proteins extd. greatly depends on the strength of the alc.; the presence of a small quantity of MeOH as denaturant does not interfere. After refluxing, fill the flask with its hot contents approx. to the mark with 95% EtOH, shake, fill exactly to the mark after cooling, shake again and let stand to settle overnight, or at least 2 hrs. Filter the supernatant liquid quickly through asbestos placed in a tube so as to obtain 150–160 cc. of filtrate in the first 15–20 mins. Take by means of a pipet 15–25 cc. of the transparent filtrate, evap. in a Kjeldahl flask, add 5–7 cc.  $H_2SO_4$ , sp. gr. 1.84, and det. N by the Kjeldahl method. Calc. the % of the maize admixt. by the formula  $X = (A - 26)/5.84$ , where  $X$  is the % of maize flour,  $A$  is N expressed in mg. and calcd. on an ext. from 100 g. air-dry flour. (In this calcn. it is conventionally assumed that flour occupies in the extn. flask a vol., in cc., equal to its weight in g.) If the flour contained in addn. some rye, the exactness of the maize detn. would be but little affected: a 25% admixt. of rye would appear as a 1% admixt. of maize. If barley meal is also present, the result will practically not be affected. This method is exact and simple. When applying this method to the analysis of baked bread, it is, of course, also found that the quantity of N found in the alc. ext. of maize-contg. bread is considerably higher than that of the pure wheat bread, but the proper conditions of extn. when dealing with breads have not yet been detd.

BERNARD NELSON

**Ammonium persulfate and the baking capacity of meal.** H. LÜERS AND A. SAUMWEBER. *Z. ges. Getreidew.* 16, 8–14(1929).—Bread made of meal treated with  $(NH_4)_2S_2O_8$  possesses an increased batch vol. and a finer pore formation. The persulfate has a sp. stimulating action on the yeast. The gluten is more solid and resistant while the enzymes are little changed.  $(NH_4)_2S_2O_8$  acts on some meals while others remain unaffected.

C. SCOTT

**Studies in cereal chemistry. III. The basic materials.** T. H. FAIRBROTHER. *Ind. Chemist* 5, 199–201(1929); cf. *C. A.* 23, 3277.—When barley is to be used for feed, bushel wt. and  $H_2O$  content are the important factors in grading. If it is to be used for production of malt, beer, etc., other factors to be considered are: percentage germination, thickness of husk, yield of malt, quantity of sol. ext., diastatic activity and protein content. Since oats are used primarily for food, the factors considered in grading are amt. of husk or fiber and the protein, fat, carbohydrate and ash content of the endosperm. In grading maize, bushel wt. and  $H_2O$  content are detd. An acidity test will indicate incipient deterioration. The detn. of the amt. of rye flour in a mixt. of wheat and rye flour is sometimes necessary. Cereal flours may be distinguished by a microscopic examn. of the starch granules.

AMY LEVESCONTE

**A yellow color in dough without the use of a dye.** TH. VON FELLEBERG AND J. RUFFY. *Mitt. Lebensm. Hyg.* 20, 34–7(1929).—A secret process offered for sale by a Dutch firm to Swiss millers for treating cereal groats without the use of a dye, so as to produce a yellow dough, was investigated. It was found that at least 3 cc.  $N/1$  NaOH per 100 g. groats was necessary to produce a yellow dough, which fluoresced greenish yellow in ultra-violet light. This fluorescence was due to certain constituents of the hulls. Dough untreated with NaOH gives a bluish fluorescence. Groats treated with NaOH can also be detected by the alky. of the ash.

B. C. BRUNSTETTER

**Report on (the determination of alumina in) baking powders and baking chemicals.** L. H. BAILEY. *J. Assoc. Official Agr. Chem.* 12, 206–8(1929).—Wohlk's volumetric method (*C. A.* 22, 3112) was found unsatisfactory. Hess and Campbell's phenylhydrazine bisulfite method (*J. Am. Chem. Soc.* 21, 776(1899)), with some slight modifications, gave satisfactory collaborative results, and will be studied further.

A. PAPINEAU-COUTURE

**Regulations for the enforcement of the Federal import milk act.** Food, Drug and Insecticide Administration, U. S. Dept. Agr. *Service & Regulatory Announcement* I. M. No. 1, 6 pp.(July 21, 1927).—The text of "An act to regulate the importation of milk and cream into the U. S. for the purpose of promoting the dairy industry of the U. S. and protecting the public health" is given with the regulations adopted.

H. A. LEPPER

**The value of milk pasteurization at 63° to 65° for the prevention of tuberculosis.** H. RAUTMANN. *Z. Fleisch. Milchkhyg.* 37, 185–9(1927); *U. S. Pub. Health Eng. Abstracts* E-789b, 16.—Low-temp. pasteurization (63° to 65°) properly applied can be relied upon to destroy the tubercle bacilli.

C. R. FELLERS

**Antigenic properties of evaporated milk.** ORAN T. CUTLER. *J. Am. Med. Assoc.* 92, 964(1929).—The heating of cow milk in prepn. of evapd. milk does not change

the antigenic capacity of the casein as detd. by anaphylactic reactions. There is an alteration of whey protein during such heating as is shown in the change in specificity whereby heated whey proteins are less reactive in animals sensitized with raw or pasteurized milk, or with antibodies against pasteurized milk. R. C. WILLSON

**Malted milk: a study of the action of the enzymes of malt upon milk solids during manufacture.** B. G. HARTMANN AND F. HILLIG. *J. Assoc. Official Agr. Chem.* 12, 223-38(1929).—An investigation into whether biol. activities occur in the evapn of the mixt. of malt infusion and milk in the manuf. of malted milk. A study of the effect of temp. on the conversion of starch in the mashing process showed that: the mashing temp. does not materially affect the H-ion concn.; the highest sugar degree (% sugar in solids) is obtained at 45°; for complete conversion of starch a temp. of 65° is necessary; and a malt infusion prep'd. at 65° has a  $p_H$  of about 5.7 and an acidity of approx. 0.14% as lactic acid. Under the conditions of the expts. no lipolytic action took place when malt infusions prep'd. at 30-65° were permitted to act on butter fat or powd. whole milk; since the temps. and  $p_H$  ranges used cover the conditions that may occur in factory practice, it is very doubtful that digestion of fat occurs during the mfg. process. This conclusion is open to the criticism that the expts. did not take into consideration the concn. of the enzyme through the progressive removal of  $H_2O$ , under which circumstances increased activity is possible. The expts. showed that proteolytic activity undoubtedly occurs when a properly prep'd. malt infusion is permitted to react with milk proteins, but that no proteolytic digestion occurs during the first 3 hrs. of evapn. as conducted in the factory; but whether there is an action of proteolysis during the final evapn. to dryness, through the concn. of the enzyme, is not demonstrable in the lab. Expts. with a no. of the better known brands of malted milk, wherein sol. starch was used as the substrate, showed only slight digestion when tested with I; this may be due to the high  $p_H$  of these products (about 7.2), as the expts. have shown that max. starch conversion takes place at 45° at a  $p_H$  of about 5.9. Even after long storage (2 yrs.) at room temp., malted milk has distinct digestive properties. Organoleptic observations made on malted milk prep'd. in the usual manner and on products obtained by drying inactivated malt-infusion-milk mixts showed both kept equally well by storing 2 yrs. at room temp., contrary to the generally made claim that the action of enzymes in the process of manuf. improves the keeping qualities of malted milk. A. PAPINEAU-COUTURE

**Report on (the determination of lactose in) malted milk.** B. G. HARTMANN. *J. Assoc. Official Agr. Chem.* 12, 201-2(1929).—By use of the modified fermentation method proposed by Allen (*Proc. World's Dairy Congress* 2, 1316(1923)), which consists essentially in fermenting the material under aeration and detg. the residual lactose by Cu reduction, acceptable results were obtained when lactose was detd. in pure soln. and in admixt. with sucrose or pure dextrose (cerealose); but malt ext., com. glucose and com. invert sugar leave a considerable residue after fermentation, which reduces Cu. A very decided reduction of the interfering residue was obtained by fermenting with yeast that had been activated by incubating overnight at room temp. in a cerealose soln. A. PAPINEAU-COUTURE

**The microscopical identification of malted milk and its flavored products.** F. HILLIG AND B. G. HARTMANN. *J. Assoc. Official Agr. Chem.* 12, 238-40(1929).—Photomicrographs are given and explained of genuine malted milk, spray-dried whole and skim milk, spray-dried and drum-dried malt ext., cocoa and sugar, and mixts of certain of these ingredients. In true malted milk prep'd. in accordance with the definition of the U. S. Food, Drug and Insecticide Administration, the malt ext. solids and the milk solids are incorporated into homogeneous irregular fragments having a stippled surface; the appearance is so characteristic that it is considered that it cannot be mistaken for any product of similar compn. A. PAPINEAU-COUTURE

**Butter with an abnormally high Polenske number.** OTTO HÖGL AND HANS SCHELENBURG. *Mitt. Lebensm. Hyg.* 20, 37-41(1929).—Samples of butter boiled over the free flame to a dark brown color showed an av. increase of 1.5 in the Polenske no. This effect occurred only after a direct boiling of the whole butter. There was no change in the Polenske no. after heating the filtered fat from the butter. Other analytical characteristics were unaffected. B. C. BRUNSTETTER

**Metals in dairy equipment; corrosion caused by washing powders, chemical sterilizers and refrigerating brines.** O. F. HUNZIKER, W. A. CORDS AND B. H. NISSEN. *J. Dairy Sci.* 12, 252-84(1929).—The same metals were used as in a previous expt. (cf. C. A. 23, 2506). The washing solns. used were 0.5% soln. of NaOH, special alkali,  $Na_2CO_3$ , Wyandotte Cleaner and Cleanser,  $Na_3PO_4$  alone and with 0.025%  $Na_2CrO_4$ . The Al products suffered by far the most intense corrosion, then followed tinned Cu

and tinned Fe, although their resistance was much greater than that of the Al products. Of the remaining metals the Cr-Ni steel, Allegheny Metal, and the ordinary Cr steels, Ascolay and Enduro proved most resistant. Ni and Monel metal were practically immune, while Ni-Ag tarnished considerably. The corrosion of Cu, Fe, galvanized Fe and Zn was greater but not as severe as that of the tin-plated products. The chem. sterilizers used were solns. of NaClO, Diversol and Chloramine-T. Diversol was very destructive to Al, but the least corrosive. Chloramine-T showed less intense action than NaClO, but its corrosive effect was somewhat greater than Diversol. Allegheny Metal and Enduro showed no visible corrosion, and the attack on Ascolay, Ni, Monel metal, and Ni-Ag was but slight. Both neutral NaCl brine and neutral CaCl<sub>2</sub> brine were used. Portions were made alk. with NaOH, and other portions treated with NaCrO<sub>4</sub> and Na silicate, resp. Ni and Allegheny Metal resisted practically completely corrosion, then followed Enduro, Ascolay, Monel metal, Ni-Ag and Sn. Cu and tinned Fe products showed considerable corrosion. Al withstood corrosion except in alk. brines. Fe, galvanized Fe and Zn suffered heavy weight losses in all brines and very poor resistance to corrosion. The action of the Na brines was more severe than that of the Ca brines.

J. C. JURRIJENS

**Desiccation of vegetable material.** B. J. OWEN. *Domestic Eng.* 49, No. 5, 83-91 (1929).—The chief considerations in problems of drying vegetables and other agricultural products are temp. and the relation between compression, density and resistance to passage of air. Processes are described which are considered suitable for drying grasses, cereals, sugar beets, grain, apples, hops and potatoes.

E. I. S.

**Composition of raisins from Cyrenaica.** A. FERRARA. *Agr. coloniale* (Florence) 21, 5-11 (1927); *Intern. Rev. Sci. & Practice Agr.* [N. S.] 18, 467T.

E. H.

**The preservation of tropical fruits with latex.** W. SPOON. *Ber. Afdeel. Handelsmuseum Ver. Koloniaal Inst.* No. 43; *India Rubber J.* 77, 586 (1929).—Expts. on the preservation of E. Indian fruits with fresh latex, vulcanized latex and "Uterex" (Utermark centrifuged latex) are described. The fruits were dipped 2-3 times, dried, packed and shipped to Amsterdam, along with similar fruit not so treated. The expts. warrant certain general conclusions. Concd. latex gives a thicker, stronger film than ordinary latex, and both prevent the development of mold for a considerable time. Vulcanized latex films are unsuitable because they encourage mold development. With concd. latex it is difficult to obtain films of the same thickness on different fruits. Rubber films affect adversely the taste of papaws, mangoes and certain citrus fruits. In no case does the application of a rubber film have any decided advantage, for though it retards ripening, the fruits usually deteriorate without ripening after the films are removed. The tendency of vulcanized latex to encourage the growth of mold was confirmed by tests of artificial cultures of *Penicillium* (the mold found on the fruit), whereas ordinary latex and particularly concd. latex retarded mold growth. Similar expts. on mangoes and mangosteens have been described by Chevalier (*Rev. botan. appl. agr. colon.* 3, 839 (1923)) and by Cramer (*De Indische Merkuur* 48, 207 (1925); *Algem. Landbouw-Weekblad v. Ned.-Indië* 9, 1215 (1925)).

C. C. DAVIS

**Paper wrappers and their effect upon physical and chemical properties of horticultural products.** H. D. BROWN. Michigan Agr. Expt. Sta., *Tech. Bull.* 87, 29 pp. (1928).—The chem. effects of using wrapping paper on fruit and vegetable products in shipping were neg. Kraft tissue, waxed vegetable parchment, etc., were tried in the tests. The amts. of sugar in sweet corn and peas were quickly reduced upon exposure to high temp. Sugar in peas apparently first changed to acid-hydrolyzable material and then to starch. In corn the change was apparently directly to starch. Storage in low temp. retarded these changes.

J. J. SKINNER

**The method of honey-production by bees and time involved.** A. SCHÖNFELD. *Vestník Českoslov. Akad. Zemedelske* 3, No. 3, 228-31 (1927) (résumé in French); *Intern. Rev. Science & Practice of Agr.* [N. S.], 18, 486-7T.—Differences in compn. of honey produced by the same species of bee in diff. geographical locations are attributed to differences in compn. of the nectar from which the honey is made. Swarms fed on 3 different sugar solns.: (a) sugar dissolved cold in an equal wt. of water; (b) sugar dissolved hot in half its own wt. of water; (c) as in (b), but with the addn. of citric acid that presumably would help the inversion of the sucrose, gave honey of the following compns.: water 19.5, 17.4, 19.1; saccharose 26.97, 40.20, 49.18; invert sugar 51.10, 47.94, 30.32; glucose 22.33, 17.12, 14.06; fructose 28.77, 20.82, 10.26; albuminoids 9.206, 0.144, 0.125. The bees inverted, resp., 48.14, 37.46 and 17% of the sucrose contained in the nutrient solns. a, b, c, hence the greater the concn. of the nectar in sucrose, the less the quantity that the bees can invert. This also applies to the activity of invertase.

H. L. D.

**Determination of glucose sirup and glucose in presence of sucrose and invert sugar.** C. I. KRUISHEER. *Chem. Weekblad* 26, 254-63(1929).—The new sugar titration method of Schoorl has been applied by K. The method has been so worked out that it is possible to obtain an exact idea of the compn. of such a mixt. for which a no. of formulas have been deduced. The method has been applied to the examn. of jams; in this case the error is not greater than 2%, independent of the corn-sugar content, and is smaller than with the methods usually applied at the present time. The method is also applicable to a mixt. contg. solid glucose instead of corn sirup, which makes it of importance in the examn. of confectionery and chocolates. J. C. JURRIENS

**Report on (the detection of artificial invert sugar prepared by enzyme conversion in) honey.** H. A. SCHUERTE. *J. Assoc. Official Agr. Chem.* 12, 151-6(1929); cf. *C. A.* 22, 2416.—From a discussion of results obtained in a collaborative investigation of the Auerbach-Bodländer method of detg. the levulose:dextrose ratio of honey, and also of both published and unpublished data, S. considers that no useful advantage would be gained at the present time in attempting to establish a levulose-dextrose ratio as an index of the presence of added invert sugar sirup. A. P. C.

**Sweetening component of some astringent "Kaki" (varieties *Dispyros kaki* L.).** MOTOE IWATA. *Bull. Inst. Phys.-Chem. Research* (Tokyo) 8, 220-2(1929); *Abstracts* 2, 27-9. (In English.)—In 1922, I. (in collaboration with Tazaki) found that *Kakishibu* (tannin-like component of "kaki" fruit) contained a white cryst. compd. of sweet taste. This is now identified as *D*-mannitol by analysis, m. p., rotary power and chem. reactions. Mannitol is therefore a notable factor in the sweetening elements of Kaki, and should always be detd. as well as the sugars. G. CALINGAERT

**Regulations for the enforcement of the Tea Act.** Food, Drug and Insecticide Administration, U. S. Dept. Agr. *Service & Regulatory Announcement* T. No. 1, 10 pp., (April, 1928).—The text of "An act to prevent the importation of impure and unwholesome tea" approved March 2, 1897, with amendments, is given with the regulations adopted. H. A. LEPPER

**Lead in oil sardines.** HEINRICH ZELLNER. *Deut. Nahrungsm. Rundschau* 4, 23-4(1929).—A case of Pb poisoning from eating canned sardines led to the analysis of a large no. of samples of different origin. From 0.2 to 3.2 mg. of Pb was found in 50% of the samples per 100 g. Sn was found in practically all samples, amounting to 3.2-13.4 mg. per 100 g. The cans contained from traces to 9.4 parts of Pb per 100 parts and the solder 49.2-65.0%, while only traces of Sb were found. The method of analysis is given in detail. J. C. JURRIENS

**Report on (the detection of) stock feed adulteration.** H. E. GENSLE. *J. Assoc. Official Agr. Chem.* 12, 148-50(1929); cf. *C. A.* 22, 2418.—The previously described method was modified by staining by the Gram method in order to accentuate the *B. lactis*, which are Gram positive, and also by triturating the feed in a mortar with water to isolate the bacteria from the milk particles. In most instances the bacteria were found in abundance by all collaborators in samples contg. buttermilk; but when the specimens represented a "cultured" product, few *B. lactis* were present. Examn. of ingredients used in stock feeds showed that many of them contained bacteria which might be confused or mistaken for *B. lactis*. Tests for the detection of buttermilk gave uncertain results when less than 2% was present. It is not advisable to sep. the bacteria, because when the actual particles of buttermilk are present they can be identified by the *B. lactis* enclosed within their areas and the danger of confusing various types of bacteria is thus avoided. A. PAPINEAU-COUTURE

**The white "zacate" of Honduras, *Ixophorus unisetus* Sch.** T. A. CALVO. *Bol. fomento* (San José, Costa Rica) 6, No. 3, 88(1927); *Intern. Rev. Agr.* [N. S.] 19, 466-- This graminaceous species is called both *Setaria unisecta* Tourn. and *Panicum unisetum* Trin. In Honduras it is used for grazing cattle. When green, air-dried and dried at 100°, resp., the plant contained water 83.87, 12.00, —; protein 1.27, 6.93, 7.87; fat 0.08, 0.46, 0.52; carbohydrates 8.28, 45.11, 51.27; fiber 4.89, 26.70, 30.31; ash 1.61, 8.80, 10.00%. The nutritive ratio was 1:10.49. H. L. D.

**Toxicity of Al compounds in the diet (McCOLLUM, *et al.*) 11E.** The physiological action of alum baking powders (SCHAEFFER, *et al.*) 11E. **Bakery furnace.** SOC. GOBERT ET CHARPENTIER. Fr. 652,060, April 2, 1928.

**Preserving foods by refrigeration.** J. E. W. REEH. Brit. 300,209, Nov. 8, 1927. See Fr. 643,666 (*C. A.* 23, 1446).

**Puffing cereal or other food products after cooking and pressing.** E. H. MCKAY (to Kellogg Co.). Brit. 300,261, Nov. 10, 1927.

**Puffed cereal products.** A. P. ANDERSON (to Anderson Puffed Rice Co.). Brit. 300,194, Nov. 8, 1927. An app. is described in which a puffed product is made by applying heat and pressure to moisture-contg. material reduced to a state such that it will flow under pressure; the treated material is passed through an annular or other orifice to permit the moisture to vaporize and produce a puffed product.

**Sterilizing liquid foods, etc.** CARL A. HARTUNG. U. S. 1,714,366, May 21. The liquid under treatment is heated in a circulating system, in an app. which is described, by indirect heat-transfer, countercurrentwise, from a liquid-heating medium, the temp. of which is so regulated as to be substantially constant and but a few degrees above the temp. of the treated liquid at any particular time and portion of the app. This avoids giving a scorched taste to foods treated.

**Sterilizing milk or other liquid foods with multiple steam jets.** GEORGE GRINDROD. U. S. 1,714,597, May 28. An app. is described suitable for sterilization of milk without giving it a "cooked taste."

**Centrifugal apparatus for use in tests such as those of milk and cream.** ROLAND J. WIGHTMAN (to Cherry-Burrell Corp.). U. S. 1,713,579, May 21. Structural features of bottle supports are described.

**Cheese.** E. S. MARTIN (to Phenix Cheese Corp.). Brit. 300,113, Nov. 5, 1927. Cheese or a mixt. of comminuted cheese with milk, cream or butter is stirred and heated to about 75° to effect pasteurization; it is homogenized by passing through small orifices under high pressure and is packed in sealed containers while hot. An emulsifier such as Na citrate may be added to the mixt.

**Apparatus for mixing, cooking and "compounding" cheese.** ALBERT S. KUX. U. S. 1,713,537, May 21. Structural features.

**Butyric acid bacteria.** MARTIN FLUBACHER. Swiss 129,468, Oct. 23, 1926. Addn. to Swiss 124,090. The development of butyric acid bacteria in stored fodder is prevented by spraying with solns. contg. such salts as NaCl, CaCl<sub>2</sub>, Na<sub>2</sub>PO<sub>4</sub> and iron lactate.

### 13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

**Eighth (French) congress of industrial chemistry.** MAURICE DESCHIENS. *Chimie & industrie Special No.*, 7-114 (Feb., 1929).—A detailed account of the proceedings, Strasbourg, July 22-30, 1928.

**The drying speed in high-temperature drying.** M. TAMURA. *J. Soc. Mech. Eng. Japan* 32, No. 142, 69-76(1929).—Relations between factors which effect drying speed in so-called high-temp. drying in one dimension are discussed, particularly for the case where effects of speeds of evapn. and osmosis are negligible. E. I. S.

**Drying in combination with power generation.** H. BALCKE. *Wärme* 52, 359-61 (1929).—Driers are in many cases an excellent medium for exhaust-steam utilization in heating and power plants. Details are given of modern high-temp. driers. E. I. S.

**Emulsions, their scope and application.** W. E. BILLINGHAM. *J. Soc. Dyers Colourists* 45, 63-7(1929).—The dispersing medium is the crux of the problem of the production of emulsions for practical use in industry, since this depends upon the continuous phase possessing the essential quality of conferring stability and permanence to the emulsion by the necessary modifications of surface and interfacial tension. A stable emulsion must contain in the dispersing medium the right stabilizer, one which is elastic and has a long breaking length. The surest way of overcoming gravity, viscosity and surface and interfacial tension is to create an emulsion system in a closed form of the material to be emulsified, using this concd. system as the emulsifying agent or dispersing medium. *Amoa Amoil* is offered as possessing universal emulsifying and stabilizing properties. S. K. FORD

**Errors of sampling and measurements rationalized by control.** A. R. R. WESTMAN. *Chem. Met. Eng.* 36, 292-3(1929).—An article presenting charts which can be used in solving systematically the problems involving errors of sampling and measurements which arise in connection with engineering tests. RASSOW, B. AND LOESCHER, A.: *Jahresbericht über die Leistungen der chemischen Technologie für das Jahr 1928. Abt. 2. Organischer Teil.* Leipzig: J. A. Barth. 612 pp. M. 36; bound, M. 39.

WASSER, BRUNO: *Der Betriebs-Chemiker.* 4th ed., revised and enlarged. Berlin J Springer. 340 pp. Bound, M. 19.50.

**Catalytic reactions.** I. G. FARBENIND. A.-G. Fr. 652,595, Apr. 12, 1928. In exothermic catalytic reactions the tubes contg. the catalysts are assembled in groups so close together that the incoming gas has a greater linear speed than that in the tubes. Cf. C. A. 23, 1227.

**Catalytic reactions.** SOC. CHIM. DE LA GRANDE-PAROISSE, AZOTE ET PRODUITS CHIM. Fr. 652,574, Apr. 11, 1928. In exothermic catalytic reactions carried out under pressure, the fresh gas is caused to arrive between the wall supporting the pressure and an inner tube contg. the catalytic material, to protect the wall against the temp. The gas is mixed with the residual gas from the reaction chamber from which the product of the reaction has been removed, and the mixt. enters a heat exchanger before passing to the reaction chamber. Cf. C. A. 23, 1701.

**Liquefying gases.** GESELLSCHAFT FÜR LINDE'S EISMASCHINEN A.-G. Fr. 651,748, Mar. 24, 1928.  $C_2H_2$  is removed from gases to be liquefied by passing the gases over catalysts such as partially dehydrated bauxite or hydrates of Fe, which will cause disson, hydrogenation, or polymerization of the  $C_2H_2$ .

**Liquefaction of gases.** SOCIÉTÉ L'AIR LIQUIDE (SOC. ANON. POUR L'ÉTUDE ET L'EXPLOITATION DES PROCÉDÉS GEORGES CLAUDE). Fr. 33,712, Mar. 25, 1927. Addn. to 638,382 (C. A. 23, 223). Oxides of N and  $C_2H_2$  are removed from gases to be liquefied by hydrogenation in the presence of a catalyst such as Cu. Oxides of N may also be removed by hot  $(NH_4)_2SO_4$  solns.

**Removing sulfur compounds from gases.** I. G. FARBENIND. A.-G. Fr. 652,243, Apr. 5, 1928. The amt. of O necessary to oxidize the S compds. and the amt. of  $NH_3$  to form  $NH_4$  salts is added to the gas, which is directed at a high temp. onto active adsorption agents such as activated charcoal or onto alloys or compds. of metals with metalloids of the 4th, 5th, or 6th group of the periodic system, with the exception of O. The gas may be mixed with insufficient O and a small quantity of  $NH_3$  and directed at ordinary temp. on to the charcoal; this is afterward treated with O or air at a high temp., either with the addn. of  $NH_3$  or absorption in aq.  $NH_3$ .

**Separating dust, water, oil, etc., from gases.** HUNDT & WEBER G. M. B. H. Fr. 651,857, Mar. 28, 1928. The gas is caused to enter tangentially a primary scpg. chamber which contains a 2nd much smaller chamber into which the gas enters by helical tubes, and which has an axial exit tube.

**Recovery of volatile compounds.** VEREIN FÜR CHEMISCHE INDUSTRIE A.-G. Fr. 651,716, Mar. 24, 1928. Products such as hydrocarbons, ethers, ketones, Cl derivs. of  $C_2H_4$ , etc., which have been recovered from air by active C or  $SiO_2$ -gel, are displaced from the adsorbent by heated  $CO_2$ , the satd.  $CO_2$  being then passed through a KOH soln.

**Recovery of solvents.** I. G. FARBENIND. A.-G. Fr. 652,406, Apr. 10, 1928. Volatile org. solvents such as  $C_6H_6$  are recovered from gaseous mixts. by washing the mixts. with the fractions b. below  $200^\circ$  of the products of the catalytic hydrogenation of oxides of C.

**Recovery of plastic materials from their solutions.** THE NAUGATUCK CHEMICAL CO. Fr. 651,939, Mar. 29, 1928. An app. is described for passing a gas such as superheated steam through plastic, gummy, or amorphous material for removal of traces of solvent therefrom.

**Dehydrating vegetable materials.** BRYNAR J. OWEN (to Sugar Beet and Crop Driers, Ltd.). U. S. 1,713,619, May 21. Material such as disintegrated sugar beets liable to be injured by excessive heat in disintegrated form is massed to a thickness of 5-12 in., an artificial drying agent such as air is passed through the material for 45-60 mins. at graduated temps. and at substantially const. vol., so that the temp. of the drying agent is highest in contact with the fresh material and is progressively reduced as drying proceeds; the vol. of the drying agent is dependent on the exit temp. at which it is discharged in a state of satn. Cf. C. A. 23, 1699.

**Degreasing articles of metal, horn, celluloid, glass, etc.** A. WACKER GES. FÜR ELEKTROCHEMISCHE INDUSTRIE GES. and G. WOLFF. Brit. 299,650, Jan. 26, 1928. The articles are treated in warm, open baths of solvents such as  $CCl_4$ ,  $C_2HCl_3$ , gasolene, or  $C_6H_6$  above which cooling surfaces are placed to prevent escape of vapors from the degreasing liquid. Various details of an app. used are described.

**Artificial ice.** MAX EULE (to Adolf Hartmann). U. S. 1,713,596, May 21. In order to prepare water for freezing to obtain substantially clear ice, difficultly sol. constituents such as gases and Ca carbonates are removed from the water; the water is then treated with a small proportion of  $\text{Na}_2\text{CO}_3$  or  $\text{NaOH}$ .

**Freezing liquids by evaporation of hydrocarbons.** SAMUEL C. CARNEY. U. S. 1,713,888, May 21. A liquid hydrocarbon material such as a blend of  $\text{C}_2\text{H}_6$  and  $\text{C}_3\text{H}_8$  is supplied to an excess of liquid, such as water, which is to be frozen, in a chamber in which a partial vacuum is maintained; part of the hydrocarbon liquid is evapd. and the excess unevapd. hydrocarbon is withdrawn from the chamber, and frozen material is withdrawn from the excess of unfrozen liquid. An app. is described.

**Refrigerators.** NATHANIEL B. WALES. Fr. 652,471, Apr. 11, 1928.

**Refrigerating systems.** A. EINSTEIN (to L. Szilard). Brit. 299,783, Oct. 31, 1927. In either compression or absorption systems, the heat of condensation is absorbed by a solid or semi-solid material such as  $\text{PhOH}$ , which melts or changes its state during a relatively short period of compression or generation and which gradually gives up its heat during the idle or evaporating periods. Absorbents such as C or substances to effect m.-p. reduction may be used with the  $\text{PhOH}$  or like substance.

**Refrigerating system of the absorption type.** BURCHARD THOENS (one-half to Burchard M. Thoens). U. S. 1,713,934, May 21. Structural features.

**Refrigerating apparatus of the compression type.** EUGENE L. BARNES (to Barber Asphalt Co.). U. S. 1,713,639, May 21.

**Refrigerating apparatus of the compression type.** H. R. VAN DEVENTER and J. A. GRIER. Brit. 299,728, Oct. 27, 1927. Structural features.

**Refrigerating apparatus of the compression type.** M. AUDIFFREN and SINGRÜN. Brit. 299,724, Oct. 28, 1927. Structural features.

**Thermostatic control device for refrigerating systems.** HOWARD W. PARTLOW. U. S. 1,713,856, May 21.

**Electric insulation.** BRITISH THOMSON-HOUSTON CO., LTD., H. W. H. WARREN, R. I. MARTIN and A. E. SMITH. Brit. 299,906, Aug. 3, 1927. Textile fabric, paper or asbestos layers are held together by a synthetic resin of the phenolic condensation type and have an outer layer coated with shellac.

**Electrical insulation.** HOMER H. LOWRY (to Bell Telephone Laboratories, Inc) U. S. 1,714,683, May 28. Material such as particles of magnetic cores for loading coils is provided with a coating, which will withstand mech. stresses and high temps without deterioration, by applying finely divided hydrated silica to the material and heating to form an adherent silica coating.

**Insulating electric conductors.** HOWARD D. SAYLOR (to Driver-Harris Co) U. S. 1,713,716, May 21. A flexible conductor such as stranded Cu wires is successively coated with loose fibrous asbestos and a non-vulcanizable rubber coating surrounding and adhering to the superficial fibers only of the asbestos layer and not exceeding about 0.03 in. in thickness.

**Heat-insulating material.** P. H. USSING. Fr. 652,391, Apr. 7, 1928. See Brit 299,266(C. A. 23, 3285).

**Bogota water-supply project.** B. RUIZ AND A. PINZON. *Anales ing.* (Bogota) 36, 461-75(1928). E. I. S.

**\$700,000 Waterworks system for Monroe, Louisiana.** M. P. HATCHER. *Mfrs. Rec.* 15, No. 12, 63-4(1929).—Improvement programs provide for filtration plant of 6,000,000 gals. daily capacity, centrifugal pumps of combined daily capacity of 28,500,000 gals. and storage tank of 500,000 gals. E. I. S.

**Report of Committee No. 1 on Standard Methods of Water Analysis.** JACK J. HINMAN, JR., et al. *J. Am. Water Works Assoc.* 21, 668-84(1929).—The work in process includes studies on: brilliant green lactose bile medium, brilliant green lactose peptone bile, non-confirming spore formers, eosin methylene blue agar, turbidity, phenol detn., mineral analysis, detn. of free Cl and detection of I and of biochem. O demand. Some work is also being done regarding microscopical exam. for plankton, etc. These as well as a few other matters are recommended to be continued.

D. K. FRENCH

Sixth report on the working of the Water Analysis Laboratory, Corporation of

**Madras, India, for the year 1927.** S. V. GANAPATI. 36 pp.(1928).—Extensive tabulated analytical data on the Madras water supply are given and discussed. Prechlorination was practiced throughout the year, the bleaching powder soln. having been applied at the entrance to the raw water conduit during a portion of the year to remove algae growths. The  $\text{Cl}_2$  dosage varied from 1 to 2.5 and averaged 1.4 p. p. m. The chlorinated raw water was of uniformly good quality, showing lactose fermenters in less than 20 cc. only on very few occasions, but as in previous years the slow sand filter effluent at several times was of very much poorer bacteriological quality than the applied water. Prechlorination reduced cleaning of the filters 21% over the previous year and slightly increased the effective life of the filters. The no. of samples from the distribution system, which would be classed as good, showed an increase from 8.5 in 1926 to 17.8 in 1927, the remainder of the samples failing to conform to accepted standards of purity. The atypical vibrios described previously (cf. C. A. 22, 654) were isolated from time to time from both the raw and treated waters. Cholera broke out in epidemic form during the period July to October. Because of failure of the West Monsoon the use of water had to be severely restricted and a no. of private wells were brought into use,  $\text{Ca}(\text{OCl})_2$  being supplied for treating the same. A government comm. has been appointed to study the supply. R. E. T.

**The determination of the degree of turbidity of water.** H. ILZHÖFER. *Arch. Hyg.* 101, 1-4(1929).—A photometric method is described for the detn. of the degree of turbidity of water. The method gives results which agree with those obtained by the use of the app. of Olszewski and Rosenmüller. E. R. MAIN

**The hydrogen-ion concentration of Bloomington water, Normal water, and of Bloomington-Normal sewage during the present school year.** H. W. ADAMS AND DON TARVIN. *Trans. Illinois Acad. Sci.* 21, 219-21(1928).—Both the raw sewage and the waters at their sources show an alk. value, the greatest variations being in the sewage. There seems to be some correlation between  $p_H$  values of these waters and the season of the year. L. L. QUILL

**Investigations on oxygen in Japanese lakes.** AUGUST THIENEMANN. *Arch. Hydrobiol.* 19, 295-8(1928).—Survey of the studies of S. Yoshimura in *Geograph. Rev. of Japan* 3, 1117-51, in which a classification of the Japanese lakes in relation to their  $\text{O}_2$  content is given. G. SCHWOCH

**Water purification and handling.** E. LINK. *Z. Ver. deut. Ing.* 73, 553-6(1929).—The water utilization per day per capita in most German cities is approx. 100 l. Self-purification in settling basins occurs by the mech. settling out of suspended matter, by the gradual decimation of bacteria and by the chem. transformation of proteinaceous org. matter to nitrates. Rapid-type filters are endorsed. Pptn. of colloidal matter by means of Al salts is best accomplished at the isoelec. pt. The  $p_H$  value for optimal pptn. should be below 7. For general chlorination of surface waters, the addn. with thorough mixing of 0.1-0.3 g. of Cl per cu. m. is recommended. Both Fe and Mn in potable water should be reduced to below 0.1 mg. per l. C. R. FELLERS

**Purification of water, containing humus, by slow sand filtration.** C. P. MOM AND K. HOLWERDA. *Mededeel. Dienst Volksgezondheid Nederland.-Indië* 17, 561-8 (1928).—The  $\text{H}_2\text{O}$  examined, contg. Fe and humic acids, could not be purified in a practical way by a slow sand filter, contg. ferruginous river sand as filter material. A clear filtrate was obtained but the filter was obstructed in from 2 to 4 days. The cause of this obstruction was principally in the filter film, which appeared to consist mainly of a ppt. of Fe-humic acid compds. dissolved in the raw  $\text{H}_2\text{O}$ . No indication could be obtained that organisms were present in the filter film, which caused the deposit of this ppt. J. A. KENNEDY

**Electroosmotic water purifying plant.** J. BECKER. *Eng. Progress* (Berlin) 10, 92-4(1929).—The process provides for the removal of salts dissolved in water by means of electrolysis, metal ions sepg. out at the cathode and acid residues at the anode. Deposits are free to react with electrolyte at both electrodes. App. for electroosmotic purifications of water consists of ten 3-cell systems of the type described arranged together like a filter-press. E. I. S.

**Control of washing at rapid water filtration plants.** EDWARD S. HOPKINS. *Eng. News-Record* 102, 841(1929).—Graphical data on filter washing at Baltimore, Md., show that, using a const. filtration rate (125 million gals. daily per acre) with the applied water properly coagulated and having a turbidity of 4-7 p. p. m., the length of filter runs increases as the turbidity of the final wash water decreases, becoming const. for a final wash-water turbidity of 75 p. p. m. The velocity of washing has considerable influence, a final turbidity of 800 p. p. m. with velocity of 2.9 ft. vertical rise per min. giving a longer filter run than 400 p. p. m. with a velocity of 2.3 ft. At Balti-

more the time required to obtain a final wash-water turbidity of 75 p. p. m. varies from 6 mins. at a velocity of 2.3 ft. vertical rise per min. to 4 mins. at velocities of 2.7 and 2.9 ft. per min. A 4-min. wash at 2.7 ft. is therefore the most economical. Observations on filters washed by 7 experienced operators on the basis of casual inspection of the wash water showed the final turbidity varied from 25 to 150 p. p. m.

R. E. THOMPSON

**The effect of potassium permanganate in eliminating iron from drinking water.** C. P. MOM AND O. H. VAN DER HOUT. *Mededeel. Dienst Volksgezondheid Nederland-Indië* 17, 550-60 (1928).— $\text{Fe}(\text{HCO}_3)_2$  occurring in subsoil water is not completely oxidized by aëration. The use of a contact substance such as  $\text{Fe}(\text{OH})_3$  or  $\text{MnO}_2$  is necessary to remove the Fe under these circumstances. During this process, adsorption of  $\text{Fe}(\text{OH})_3$  and O takes place.  $\text{KMnO}_4$  in a quantity equiv. to the Fe<sup>++</sup> to be oxidized can completely oxidize the latter and coagulate the  $\text{Fe}(\text{OH})_3$  produced. Cl and  $\text{H}_2\text{O}_2$  do not exert this effect.

J. A. KENNEDY

**Zeolite water softening plant at Mangum, Okla., uses open basins instead of pressure tanks.** H. B. CRANE. *Eng. News-Record* 102, 900-3 (1929).—The hardness of the water supply of Mangum, derived from 5 dug wells about 40 ft. deep, increased with the amt. of water drawn from the wells; a softening plant was recently installed. Investigation indicated that zeolite softening would be more economical than lime-soda or lime-zeolite treatment. The plant is of 1,000,000 gals. capacity and consists of raw and treated water reservoirs and softening beds. The water passes upward through 12 in. of graded gravel and through 66 in. of zeolite contained in open concrete basins, unsoftened water being automatically added to the effluent to give a water of 3 grains hardness per gal. Operating cycle consists of 5½ hrs. softening and ½ hr. regeneration, 4% salt soln. being used for the latter, distributed through the same headers and laterals as the raw water. The cost of the softening plant was approx. \$45,500. The hardness of the well water is 30 grains per gal.

R. E. THOMPSON

**The cost of softening water by the base exchange process.** H. G. CATHCART. *Domestic Eng.* 49, No. 4, 70-4 (1929).

E. I. S.

**Crenothrix in ground water supplies.** KENNETH W. BROWN. *J. Am. Water Works Assoc.* 21, 750-7 (1929).—See *C. A.* 23, 1194.

E. C. M.

**A simple method for the extraction of fresh water from sea water, salines, polluted water, any watery substances, or from the atmosphere, by means of solar heat.** JULIUS RICHARD. *Bull. Inst. océanographique* (Monaco) No. 535, 27 pp. (1929).—A pane of glass is tightly set over a frame tank or shallow basin which is filled with salt water. The glass is set at an angle of approx. 20° with the horizontal and facing the sun. A draining device carries the condensed  $\text{H}_2\text{O}$  from the lower part of the pane to a receiving bottle. Beginning on Mar., 1928, the av. daily amts. of fresh  $\text{H}_2\text{O}$  (cc.) obtained per sq. m. of exposed surface were: Mar. 1171, Apr. 2173, May 3032, June 3450, July 3440, Aug. 2970, Sept. 1697, Oct. 1277, Nov. 735, Dec. 525, Jan. (1929) 663 and Feb. 782. By the use of mirrors to obtain greater heat, the yield was materially increased. The app. proved suitable for the reclamation and purification of EtOH. Fruits were also evapd. by the use of the equipment without the usual loss in flavor.

C. R. F.

**Comparative determination of the actual reaction of moor waters. II. Employment of the quinhydrone method.** I. A. SMORODINTZEV AND A. N. ADOVA. *Arch. Hydrobiol.* 19, 323-30 (1928).—The values obtained in detg. the  $p_{\text{H}}$  of moor water according to the quinhydrone method and the indicator method without buffer were compared with those obtained by means of the H electrode. In the acid moor waters both the quinhydrone and the bufferless indicator methods gave good results, while in the alk. waters of the moors of the Segge type the deviations from the values obtained with the H electrode were often considerable. As to the indicators used, *p*-nitrophenol, 1,2- and 1,4-dinitrophenol gave satisfactory results, while *m*-nitrophenol did not. The waters of the *Sphagnum* moors had a  $p_{\text{H}}$  of 3.82-5.60; they were poor in animal and plant life. No larvae of *Anopheles* were found in waters with a  $p_{\text{H}}$  of below 5. The waters of the Segge moors had a  $p_{\text{H}}$  of 7.40-8.47. During the time of observation (June to September) there occurred only slight changes in the  $p_{\text{H}}$  of the individual moor water. The  $p_{\text{H}}$  falls slightly with increasing age.

G. SCHWOCH

**The actual reaction of the heath-moor "Seefeldler" near Reinerz and the significance of the hydrogen-ion concentration for the individuality of the moor fauna.** O. HARNISCH. *Arch. Hydrobiol.* 19, 299-300 (1928).—On account of his own careful investigations, which show that water of the moor "Seefeldler" had a  $p_{\text{H}}$  of 3.8-4.0, H. withdraws his attack against S. N. Skadowsky's theory that the high acidity of the moor water is responsible for the scarceness of animal life in heath moors.

G. S.

**Water treatment to prevent embrittlement.** FREDERICK G. STRAUB. *J. Am. Water Works Assoc.* 21, 511-23(1929).—See *C. A.* 23, 2231. E. H.

**Rational selection of a feed-water treatment.** C. E. JOOS. *Paper Trade J.* 88, No. 15, 36-44(1929).—A discussion of the following factors in connection with the use of softened water in boilers, particularly when high pressures are used: degree of remanent hardness, corrosiveness of the water, reduction in total dissolved solids and suspended matter, protection against embrittlement of the boiler metal, cost of treatment including blowing down. The importance of the use of phosphate treatment to keep down the caustic alk. at high pressures is explained. A. P.-C.

**Condensate as boiler feed.** C. N. RIDLEY. *Eng. and Boiler House Rev.* 42, 406, 408(1929). E. I. S.

**Corrosion in steam heating systems.** F. N. SPELLER. *Plumbers Trade J.* 86, 701 4, 752(1929).—Study of causes of deterioration in piping and how to treat boiler water to guard against corrosion. E. I. S.

**Priming and foaming—causes and controlling factors.** A. L. S. RUDDER. *Power House* 23, No. 5, 34, 50(1929).—Causes and prevention of discharges of water with steam are discussed. E. I. S.

**Endemic goiter in Tennessee.** ROBERT OLESEN. *Pub. Health Repts.* 44, 865-97(1929).—There appears to be no relationship between the amt. of endemic goiter and the sources, treatment and ultimate safety of public water supplies in Tenn. There is a slightly larger incidence of endemic goiter among the users of chlorinated drinking water than among the consumers of unchlorinated water. In Oregon the incidence of endemic goiter is slightly greater among the users of unchlorinated water. There appears to be no relationship between geologic formations in Tenn. and the varying incidence of endemic goiter. The author discusses prophylaxis and makes a number of specific recommendations. J. A. KENNEDY

**Water supply, sewage treatment and refuse disposal in 1928.** H. BURDETT. *Public Works* 60, 34-6(1929).—A brief review of the progress and of the completed and projected improvements is given. C. C. RUCHHOFF

**Odor control at Haddonfield sewage plant.** LEROY FOREMAN. *Public Works* 59, 425-7(1928).—All units of the plant were responsible for the odors. The odors were apparently the result of the reduction of sulfates in the liquor to  $H_2S$ . The odors could be controlled by the use of  $Cl$  or  $FeSO_4$ . About 20 p. p. m. of  $Cl$  or 25 p. p. m. of  $FeSO_4$  was required. C. C. RUCHHOFF

**Excluding inflammable oils from Baltimore sewers.** C. E. KEEFER. *Public Works* 59, 484-5(1928).—An ordinance was passed prohibiting the disposal of all waste oils into the sewers and requiring its storage and collection under the supervision of the city officials. A contract has been made with a private company for the collection and disposal of this material. The collector uses 3 trucks and collects from 1000 to 1500 gals. daily. This is disposed of by refining. C. C. RUCHHOFF

**The sewage treatment plant of the Bloomington and Normal sanitary district.** CHARLES C. BROWN. *Munic. News and Water Works* 76, 32-5(1929).—A general description of the sewage disposal problem and the new plant is given. The plant is of the Imhoff tank and sprinkling filter type and is designed for a population of 54,000. C. C. RUCHHOFF

**Rye Beach sewage-disposal plant.** D. J. SHAW. *Public Works* 59, 420-2(1928).—The old plant which was abandoned was located in an amusement park. The sewage was pumped from the old plant over a ridge to a new plant. At the new plant the sewage passes through a grit chamber, bar screens and Reinch Wurl type fine screens. It is then chlorinated and pumped to a new outfall. C. C. RUCHHOFF

**Digestion of sewage screenings at Milwaukee.** DARWIN W. TOWNSEND. *Public Works* 59, 459-64(1928); cf. *C. A.* 23, 3040.—The exptl. sewage-screenings digestion plant with a capacity of about 464 cu. ft. of screenings per day is described. The plant includes 4 tanks, each capable of taking  $\frac{1}{12}$  of the total daily screenings production or 116 cu. ft. and is designed to collect and utilize the gases of decompn. for maintaining the optimum temp. conditions in the plant. The digested screenings are to be disposed of by mixing with the waste activated sludge or by returning to the raw sewage or by drying on sand beds. Fifteen sand beds have also been constructed for studying this method of disposal. C. C. RUCHHOFF

**Digesting sewage screenings at Milwaukee.** WILLEM RUDOLFS, H. M. HEISIG AND D. E. BLOODGOOD. *Public Works* 60, 24-7(1929); cf. *C. A.* 23, 3039.—A mixt. of 200 gals. of fine screenings and 60 gals. of ripe sludge contg. 3.45% total solids of which 18.1% was ash was digested in a covered tank at 80° F. The  $pH$  was maintained at 7.4 with lime and daily B. O. D. detns. were made during the 290 days of the exptl.

During the last 188 days daily charges of 5 gals. of fine screenings (av. 1.7 lbs. per day dry solids) were added. The av. solids content of the screenings added was 5.33% and of the digested sludge drawn 3.5%. The total solids reduction during the period was 61.6%. This was possible because the material contained 92.1% volatile matter. The av. ash increase was 265% and the av. fat reduction was 56%. The sludge drawn was black, appeared well digested and drained readily. Conclusion: 0.115 cu. ft. per capita capacity was necessary for digesting fine screening. C. C. RUCHHOFF

**Biological effects of sewage effluents in streams.** R. W. BUTCHER. *Public Works* 60, 22-3(1929).—The effect of small and weak sewage effluents which produce no visible pollutional effect in streams is discussed. Such effluents do produce deleterious effects due to their O requirements, org. matter and high silt content. Very weak sewage favors the growth of diatoms, stronger sewage unicellular algae and flagellates and still stronger the pollutional forms *Carchesium septomitus lacteus* and *Sphaerotilus natans*. The bottom animals have been divided into 3 groups depending upon the character of the bottom. The first group which lives only upon a clean bottom and is driven away by sewage deposits includes water shrimps, may fly and caddis larvae and numerous other forms. This group forms the usual and best food for fish and since the weakest effluents reduce the nos. of this group it is presumed that a harmful effect upon fish results. Also in *Eng. Sanit. Record* 82, 589(1928). C. C. RUCHHOFF

**Some biochemical factors in sewage and sludge treatment.** WILHELM RUBOLFS. *Public Works* 59, 483-4(1928).—The decompn. of the unstable org. compds. in sewage sludge is dependent upon phys., chem. and biological factors which are interdependent. Ripe sludge, which when mixed with fresh solids shortens the digestion time, does not retain its inoculation value indefinitely and should not be over 2 to 3 months old. A partially decompd. material is poor for seeding purposes while sludge at the peak of gasification is excellent. A favorable reaction is important for biological activities and the proper reaction may be more easily maintained by suitable buffer solns. The enzymes which were found in sludge include diastase, lipase, pepsin, trypsin, catalase, invertase and rennet. These vary in abundance during digestion. Some of them increase and then decrease before others reach their max. The colloidal material in an undisturbed digesting sludge increases and then decreases and at the same time the chem. compn. of the colloidal material changes. C. C. RUCHHOFF

**Notes on practical sludge digestion.** JOHN R. DOWNES. *Public Works* 59, 423-5(1928).—Very important points for good sludge digestion in Imhoff tanks or scp digestion tanks are: the effectiveness of the settling tanks from which the solids are collected, provisions for the prompt removal of solids to the digestion chamber, the adequacy of the provision of ultimate disposal of the sludge. The effects of temp. and barometric changes are discussed. Gas collection and utilization are advocated for odor control and for the production of favorable digestion conditions, besides for the value of the gas as a fuel. C. C. RUCHHOFF

**Methods of sludge disposal for small sewage plants.** FRANK BACHMANN. *Munic. News and Water Works* 76, 13-4(1929).—The methods which are discussed include disposal by lagooning, by filling in low lands, by direct application to land and by plowing in and on prepd. sand beds. Dried sludge may be disposed of as a fill or as fertilizer. C. C. R

**Small activated-sludge plant in Texas has special features.** E. W. STEEL. *Eng. News-Record* 102, 761-3(1929).—The 0.5-million gal. daily activated-sludge plant of Mercedes, Tex., has 2 unique features which effect a considerable saving in power: pre-aëration without activated sludge and air diffusion through 4-in. horizontally placed porous cylindrical tubes suspended so that their centers are 4 ft. 2 in. below the flow line. The plant consists of presedimentation, pre-aëration, activated sludge and final settling compartments, the excess activated sludge being digested with the presedimentation sludge. Pre-aëration has little effect upon nitrification but affects a considerable reduction in O<sub>2</sub> demand; tests indicate that it materially reduces the time necessary for aëration with activated sludge. Aëration for 3½ hrs. with sludge at a rate of 0.6 cu. ft. of air per gal. brings about stability and practically complete nitrification. The net amt. of air, excluding waste, is somewhat less than 0.5 cu. ft. per gal. At the present flow of 0.15 million gal. daily the power consumption is 34 h. p. per million gals. equiv. to a cost of \$18 per million gals. It is estd. that when the plant is operated at full capacity the power consumption will be 8.5 h. p. per million gals. and the cost \$4.50 to \$6 per million gals. The cost of the plant was \$35,000. R. E. THOMPSON

**Land disposal of activated sludge at San Marcos, Tex.** E. G. EGERT AND CHESTER COHEN. *Eng. News-Record* 102, 830-1(1929).—Excess activated sludge from the 0.35-

million gal. daily San Marcos plant is disposed of without nuisance by discharging into furrows in 6 acres of land. After drying, the surface crust is broken by a single plowing down the center of the furrow and the land is again ready for use. The effluent from the plant is treated with  $\text{Cl}_2$  to protect a bathing resort downstream from the plant.

**Activated-sludge disposal plant at Charlotte, N. C.** E. G. McCONNELL. *Public Works* 59, 438-44(1928); cf. *C. A.* 22, 4690.—The new 5 m. g. d.-capacity activated-sludge plant is described. The sewage is passed through preliminary settling tanks before aeration. The preliminary settled solids and the activated sludge are digested in tanks equipped to recover the gas produced. One of the air compressors in the plant is being driven by a gas engine using the gas produced at the plant; it has reduced the power costs. Some difficulty due to bulking of the activated sludge has been experienced, but has not interfered with its digestion.

**Sludge disposal in England.** J. H. GARNER. *Public Works* 60, 65-7(1929).—Sludge is disposed of by pumping on land either by plowing under or by trenching. For this method the Royal Commission on Sewage Disposal recommends about  $1\frac{1}{4}$  sq. yds. per capita for domestic sewage sludge of 90-95% water. The most widely used method of drying sludge is upon specially constructed sand filter beds the same as in our country. Chem. treatment with lime and "aluminoferric" is used to hasten dewatering.

**Report of Bureau of Sanitary Engineering, Maryland State Dept. of Health, 1928.** ABEL WOLMAN. 19 pp. (mimeographed, 1929).—The activities of the Bureau during 1928 are reviewed and discussed. Substantial progress was made during the year in improving stream conditions, routine sampling of the water courses at various points having proven an effective means of pollution control. The treatment of the following industrial wastes was studied: paper mill, laundry, garbage reduction, steel rolling mill and cannery. Details are given of new water and sewage works constructed and of improvements and addns. to existing plants carried out during the year. Special investigations relative to water supply, oyster pollution, sewage disposal and aerial pollution conducted by the Bureau are outlined. The typhoid mortality rate was by far the lowest in the history of Maryland, being 5.2 per 100,000 for the State, 4.2 for City of Baltimore and 6.5 for the counties.

**Purification of swimming-pool water.** G. C. DUNHAM. *Military Surgeon* 64, 361-73(1929).—During the summer of 1928, a study was made of the comparative effectiveness of continuous and intermittent chlorination in the operation of a swimming pool at Carlisle Barracks. The  $\text{Cl}$  enters the pool through a pipe in the wall at the deep end at mid-depth and is diffused by the bathers. The presence of *B. coli* was detd. by a modified presumptive test—10 cc. of  $\text{H}_2\text{O}$  were inoculated into 30 cc. of lactose broth; the presence of more than 10% of gas after 24 hrs. incubation was indicative of *B. coli*. With intermittent chlorination it was shown that as the no. of bathers (cumulative) increased the excess  $\text{Cl}$  content decreased to zero and presumptive tests for *B. coli* changed from neg. to pos. With continuous chlorination—excess  $\text{Cl}$  always being present—presumptive tests for *B. coli* were always neg.

**Refuse disposal in Borough of Brooklyn, New York City.** E. L. COLLINS. *Eng. News-Record* 102, 862-3(1929).—A description of refuse disposal in Brooklyn, which is carried out by contract. The refuse is sorted on conveyor belts at 15 stations and unsalable material is destroyed by incineration, the residue being employed for land fill. Brief details are given of three 500-ton incinerators which are under construction.

**Routine records of collection service for refuse material.** SAMUEL A. GREELEY. *Munc. News and Water Works* 76, 21-3(1929).—The importance of collecting complete collection service and cost records is discussed.

**German exposition of gas and water technology (ALBACH) 21.** Apparatus for continuous cooking of garbage (U. S. pat. 1,715,065) 1. Electric conductivity-testing apparatus for determining the purity of boiler-feed water (Brit. pat. 300,229) 4.

**Automatic regeneration of base exchange water-purifying substances.** ÉTABLISSEMENTS PHILLIPS ET PAIN (SOC. ANON.). (Emmanuel Breuil, inventor.) Fr. 652,665, Apr. 13, 1928.

**Treating acidified mine water.** JOHN T. TRAVERS (to Travers-Lewis Process Corp.). U. S. 1,714,828, May 28. Acidified mine water such as that contg. Fe salt and  $\text{H}_2\text{SO}_4$  is caused to come into impact with and to flow through successive bodies of travertine in order to avoid stream pollution.

**Scale solvent and sealing composition.** JOHN M. COUGHLIN (to Scale Solvent & Products Co.). U. S. 1,715,337, May 28. A compn. suitable for use in boilers and water-supply systems is formed of "soluble glass" soln., coffee ext. and a diluent such as water.

**Apparatus for separating suspended solids from sewage, etc.** MARCUS B. TARK (to Link-Belt Co.). U. S. 1,714,739, May 28. Structural features.

**Apparatus for incinerating garbage or other refuse.** WILLIAM F. DREW. U. S. 1,714,005, May 21. Structural features.

## 15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

**John Kerfoot Haywood (1874-1928).** W. W. SKINNER. *J. Assoc. Official Agr. Chem.* 12, No. 2, ii-v (May 15, 1929).—An obituary with portrait. A P C

**The chemist's aid to agriculture.** CHAS. M. A. STINE. *Chemicals* 30, No. 25, 7-9; No. 26, 7-8 (1928).—An address. E. J C

**Report on (the determination of) less common metals in soils.** J. S. McHARGUE. *J. Assoc. Official Agr. Chem.* 12, 146-7 (1929).—A detailed description is given of the technic recommended for the bisulfate fusion method for the detn. of Mn in soils. A. PAPINEAU-COUTURE

**Report on (the determination of) reaction value of acid soils.** E. T. WHERRY. *J. Assoc. Official Agr. Chem.* 12, 145-6 (1929); cf. *C. A.* 22, 2427.—In stating reaction values of soils, the  $p_H$  no. should be supplemented by the corresponding values of H- or OH-ion concn. The most convenient way to express these is to make use of units of  $10^{-7}$  g. per l. of H ion and  $17 \times 10^{-7}$  g. per l. of OH ion. These units represent the ionic concns. in pure  $H_2O$  at about  $18^\circ$ , a temp. selected to make the exponent a whole no. To calc. H-ion concns. in these units, the following formulas may be used.  $H^+ = 10(7-p_H) - 0.1(7-p_H)$ ;  $OH^- = 10(p_H-7) - 0.1(p_H-7)$ . In both cases, when the 1st of the 2 terms  $> 10$ , the 2nd term may be neglected. A P C

**Contribution to the study of solonetz in the chernozem belt of western Siberia.** K. P. GORSHENIN. *Pochvovedenie (Pédologie)* [N. S.], 22, No. 3, 42-59 (1927), *Egypt Sta. Record* 59, 611.—A series of chemical analyses of samples from alkali soil profiles, differing by the depth of the A horizons, is presented, together with the morphological structure of the various types of solonetz. H I D

**A new, simple, and rapid method for determining the moisture equivalent of soils, and the role of soil colloids on the moisture equivalent.** GEORGE J. BOUYOUCOS. *Soil Sci.* 27, 233-42 (1929).—A new, simple method is described for detg. the moisture equiv. of soils for use as a single value factor. This is also correlated with the results from the hydrometer method for mech. analyses of soils. The moisture-equiv. method consists of connecting a Büchner funnel with a suction flask, placing a sample of soil into the funnel with a filter paper at the bottom, thoroughly soaking the soil with  $H_2O$ , and allowing the suction force from running water to operate for a definite length of time. There is a close relationship between colloid content and moisture equiv. The ratio of percentage of  $H_2O$  divided by percentage of colloids present is fairly const., the av. for 22 soils being 0.6224 with extremes of 0.510 and 0.713. There is no relationship between coarse silt and sand and the moisture equiv. M. S. ANDERSON

**Studies of certain phases of the interrelationship between soil and plant. I. Availability of mineral plant nutrients in relation to the degree of dispersion.** WALTER THOMAS. *Soil Sci.* 27, 247-70 (1929).—A critical digest is given of the literature dealing with the permeability to and adsorption of colloidal materials by living plant cells. An extensive bibliography is appended. M. S. ANDERSON

**The chlorate method for the determination of nitrate nitrogen, total nitrogen and other elements in soils and plant tissues.** E. M. EMMERT. *J. Assoc. Official Agr. Chem.* 12, 240-7 (1929).—A method has been devised for detg. nitrate and total N giving results that compare very favorably with those of the Kjeldahl method in a much shorter time, and leaving a residue in such a state that the other inorg. elements (except Na and S) also may be detd. easily. The principle of the method, the technic of which is described in detail, is essentially as follows: To a sample contg. 0.5-1.0 mg. nitrate N in a 500-cc. Kjeldahl flask add 20 cc. of 50% by vol.  $H_2SO_4$ , connect the flask to a condenser, the free end of which leads through a 2-holed rubber stopper into a 200-cc. cylindrical absorption tower contg. 150 cc. of freshly prepd.  $ClO_2$  soln., the 2nd hole being fitted with a Hopkins form Kjeldahl trap adjusted to such a depth that a portion of the tower contents is forced into it; heat the Kjeldahl flask to expel

the gases rapidly (but not violently) until white fumes begin to be evolved, save the residue for detn. of reduced N; to an aliquot of the  $\text{ClO}_2$  soln. contg. at least 0.25 mg. nitrate N add (while hot) 0.05–0.1 g.  $\text{Ag}_2\text{SO}_4$ , let stand 5 mins. with occasional shaking, add 0.5–1.0 g.  $\text{CaO}$ , let stand a few mins. with intermittent shaking, filter repeatedly till clear, evap. to dryness an aliquot contg. at least 0.2 mg. nitrate N, and det. the latter colorimetrically by means of phenoldisulfonic acid. Cool the residue from the distn., add 10 cc.  $\text{H}_2\text{O}$ , cool to room temp., add 1 g.  $\text{NaClO}_2$  for each 0.1 g. of dry tissue or for each 0.5 g. of green tissue or soil; before connecting heat rapidly until the green fumes of Cl peroxide first evolved are decompd. with a slight explosion and only white fumes are present. Connect immediately to the distn. app.; after violent reaction ceases distil rapidly into  $\text{H}_2\text{O}$  contained in the absorption tower, disconnect the Kjeldahl flask as soon as the soln. remains colorless; white fumes form and  $\text{H}_2\text{SO}_4$  condenses on the sides; det. N in the distillate as previously described. To det. total N, put into a dry 500-cc. Kjeldahl flask a smaller sample than that used in detg. nitrate N, add  $\text{NaClO}_2$  at the same rate as for reduced N, wash down the sides with 25 cc. of 50% by vol.  $\text{H}_2\text{SO}_4$ , and proceed as in the detn. of reduced N. For the detn. of non-volatile elements, tilt the Kjeldahl flask slightly downward (but not so much that the contents run out), support the end of the neck on a beaker, distil the residue rapidly till only a melt of  $\text{Na}_2\text{SO}_4$ ,  $\text{NaHSO}_4$  and the inorg. plant constituents remain, let cool, dissolve in hot water and make to a convenient known vol. for aliquoting; if a detn. of Na is desired, use  $\text{KClO}_3$  instead of  $\text{NaClO}_2$ . While detg. total N with  $\text{NaClO}_2$  a large quantity of gas is evolved and C entirely disappears; though a good proportion of this gas is  $\text{CO}_2$ , it comes off so rapidly that KOH bulbs will not absorb it all. In order to collect the gas a 2-l. Florence flask was filled with acidulated water and connected to the absorption tower used for collecting N; another tube led from this flask to a 3-l. flask, so that when the gases were evolved through the absorption tower they displaced the water from the 2-l. to the 3-l. flask. After complete distn. the system was disconnected from the condenser and connected to the following absorption train: (1) absorption tower contg. a satd. KI soln., acidified with  $\text{H}_2\text{SO}_4$ , to catch Cl; (2) small bubble tube contg.  $\text{AgNO}_3$  in  $\text{HNO}_3$  to note whether traces of Cl were coming over; (3) U-tube contg.  $\text{P}_2\text{O}_5$  and glass wool to absorb  $\text{H}_2\text{O}$ -vapor; (4) weighed Fleming soda-lime and  $\text{P}_2\text{O}_5$  bulb; (5)  $\text{H}_2\text{SO}_4$  scrubber; (6) bottle of  $\text{Ba(OH)}_2$ , to indicate loss of  $\text{CO}_2$ . The app. was connected to a suction pump and means provided for measuring the vol. of gas drawn out, so that several aliquots of gas from the same sample could be used. Results checked to within 0.2%, which is considered good for the large quantity of C present.

A. PAPINEAU-COUTURE

**Reclamation of Fresno type of black alkali soil.** W. P. KELLY and E. E. THOMAS. Calif. Agr. Expt. Sta., *Bull.* 455, 37 pp. (1928).—Field expts. have shown that the crop-producing power of the Fresno black alkali soil can be greatly improved by the use of gypsum, S,  $\text{FeSO}_4$ , or alum, provided these materials are applied in sufficient quantities. Yields of alfalfa ranging from 6 to 11 tons per acre per annum have been produced on land, which at the beginning of the expts. was entirely unproductive. The unproductivity of this soil is due to (a) an excess of sol. salts, especially  $\text{NaHCO}_3$ , and (b) the abnormal chem. composition of the clay-like constituents of the soil. The reclamation of the soil must involve the removal of the excess of sol. salts and the conversion of at least a part of the clay constituents into Ca compds. The former may be leached out, but ordinary leaching fails to bring about the needed chem. changes in the latter. Gypsum, S,  $\text{FeSO}_4$ , and alum produce beneficial effects on black alkali soils but at different rates. These materials act on the sol. carbonate and the clay constituents simultaneously. Gypsum brings about these changes because of its sol. Ca, while the effect of S,  $\text{FeSO}_4$ , and alum is due to their acidic nature, in consequence of which sol. carbonate is decompd. and Ca minerals of the soil, especially  $\text{CaCO}_3$ , are dissolved. The Ca thus brought into soln. reacts with the clay constituents.  $\text{FeSO}_4$  and alum react with the soil most quickly because of their high soly. and acidic nature. S acts most slowly as this material must undergo oxidation before it can produce any important effect on the soil. S has proven to be much more economical than the other materials. Large yields of alfalfa have been produced on soil that was badly affected with alkali and entirely unproductive at the outset by applying one ton of S per acre; when used in conjunction with stable manure, 1000 lbs. of S per acre has given good results. Leaching expts. without the application of any material except water have failed to bring about a satisfactory reclamation. Although the beneficial effect of S is dependent on oxidation, and the oxidation is brought about by certain species of bacteria, these expts. have not shown any special advantage for artificially inoculated S over that obtained from uninoculated S.

J. J. SKINNER

**A critical study of the influence of soil type on the calcium and magnesium content and on the physiological characters of the alfalfa plant.** JOHN F. FONDRE. *Soil Sci.* 27, 205-32(1929).—Alfalfa stems and leaves and the expressed juice of stems and leaves grown on 7 soil types were analyzed for Ca and Mg at different stages of growth. The  $H_2O$  content and the sp. gr. of the expressed juice were also detd. There were marked differences in the Ca and Mg contents of alfalfa stems and leaves and expressed juice in plants grown on different soil types. Also, the sp. gr. of the juice varied with the soil type. Generally the Ca content was higher in the dry tissue and in the expressed juice of stems and leaves of plants grown on the heavy soils. Soil type had less influence on the second crop than on the first. In fact, the effect of soil texture was negligible in the second crop. There was no consistent relationship between soil texture and Mg content of the alfalfa plant. About equal amts. of Mg were in the tissue of the leaves and stems and also in the juice. The Ca content was always higher than that of Mg. Also, the Ca content increased as plants matured. The  $H_2O$  content of both stems and leaves decreased with maturity. More  $H_2O$  was present in stems than in leaves when plants were young but this difference tended to disappear with maturity. The sp. gr. of the expressed juice of the leaves was greater than that from the stems. The most satisfactory time to obtain alfalfa samples in order to eliminate variations due to time of day lies between noon and 4 p. m. and the least satisfactory time between 8 a. m. and noon.

M. S. ANDERSON

**The effect of boron deficiency on the growth of tobacco plants in aerated and un-aerated solutions.** J. E. McMURTREY, JR. *J. Agr. Research* 38, 371-80(1929); cf. *C. A.* 23, 2525.—It is impossible to grow tobacco plants to normal maturity in nutrient solns. contg. only the commonly accepted essential elements dissolved in distd  $H_2O$ . When 0.5 p. p. m. B was added, normal plants were grown. B deficiency is characterized by injury to the terminal bud and occurs at the bases of the young leaves, while Ca deficiency produces injury at the tips and margins of the young leaves. Eight references are given.

A. L. MEHRING

**Conditions of utilization and action of phosphates on black soils (chernozem).** V-VII. M. A. EGOROV. *Ukrainskii Khim. Zhur.* 3, Tech. Pt., 241-62(1928); cf. *C. A.* 22, 3947.—When black soils are extd. with normal solns. of  $NaH_2PO_4$  or  $Na_2HPO_4$ , the ext. is light yellow, whereas, when  $Na_3PO_4$  is used, the ext. is dark. This difference is due not only to the fact that  $Na_3PO_4$  soln. has an alk. reaction, but also to the character of the Ca phosphates formed. In general, when soils are extd. with salt solns., the more alk. the solns., the more org. matter is extd. The time of digestion of the soils with the salt soln. is an important factor: the longer the interaction, the more org. matter is extd.; however, the rate of the increase is different for different soils. The influence of the temp. at which the digestion takes place is not the same for different soils: while with 1 sample of soil a little more of org. matter was extd. at  $35^\circ$  than at room temp.; another soil sample gave the opposite result. The influence of the humidity of soil is considerable. For 1 sample of soil the quantity of sol. org. matter increased with the increase of moisture content up to 75%, then dropped; for another soil the max of extd. org. matter coincided with a 50% moisture content. The question as to the manner of introducing  $Na_2HPO_4$  depends on the character of the soil: with 1 soil the max. of extd. org. matter was obtained by introducing solid  $Na_2HPO_4$  into the crude soil, then adding  $H_2O$ , whereas with another soil a better result was obtained by operating with a  $Na_2HPO_4$  soln. The reason for this difference is that the nature of the org. matter is not the same in all soils. For the same reason the most favorable concn. of  $Na_3PO_4$  to be used cannot be established for all soils. With  $Na_2HPO_4$ , however, it is found that the more concd. the soln. the more org. matter is extd. When soils are treated with solns. of  $NaH_2PO_4$ ,  $Na_2HPO_4$  and  $Na_3PO_4$ , the formation of  $Ca(H_2PO_4)_2$ ,  $CaHPO_4$  and  $Ca_3(PO_4)_2$  takes place. Ca mono- and di-phosphates formed in the soil tend to become transformed into the hardly sol.  $Ca_3(PO_4)_2$ , and the further this transformation progresses, the more org. matter of the soil dissolves. Thus, by the quantity of dissolved org. matter one may est. the activity of reversion factors in a given soil. Expts. show that various soils differ from one another to the extent of the reversion process which they effect. *Chernozem soils*, on being first treated with a  $Na_3PO_4$  soln. and then washed with  $H_2O$ , lose more org. matter, which dissolves, than other soils. Comparatively low contents of crenic and apocrenic acids in the  $Na_3PO_4$ -sol. org. matter is characteristic of chernozem soils; the predominating fraction of these soils consists of humic acid. In other soils crenic and apocrenic acids may constitute about  $1/2$  of the sol. org. matter.

BERNARD NELSON

**Peat as a source of nitrogen.** Z. V. LOGVINOVA. *Trans. Sci. Inst. Fertilizers* (Moscow) No. 56, 1-66(1929).—The absorption of  $NH_3$  and other bases by various

types of peat is described. The moss peat contains more absorbed  $\text{NH}_3$  than the meadow peats. The upper layers of either type of peat contain more absorbed  $\text{NH}_3$  than the lower layers. The Ca in peat is present in the absorbed state and is easily replaced by Na. The moss peats give appreciable amts. of P when treated with NaCl soln.; the meadow peats give only traces. The former peats are satd. with H, the latter with Ca. Compost expts. with lime and wood ash addns. to the various peats show that the  $\text{NH}_4$  becomes nitrified; in some peats more org. N is set free and mineralized. An extensive German summary is given. J. S. JOFFE

**Liming as a factor of mobilizing phosphoric acid in the podzol soil.** D. L. ASKINAZI and S. S. YARUSOV. *Trans. Sci. Inst. Fertilizers* (Moscow) No. 57, 59 pp. (1928).—Summarizing the results of several years' expts., A. and Ya. point out that: (1) The introduction of lime into a podzolized soil increases the energy of decompn. processes and mineralization of org. matter and results in an accumulation of the mineral forms of N and phosphoric acid in the soil soln. (2) As the processes of decompn. and mineralization of the org. material slow down, the influence of the lime on the N supply to the plants becomes less and less apparent; vegetation expts. seem to indicate that the influence becomes zero at the 9th year after liming. (3) The residual effects of lime consist in improving the  $\text{P}_2\text{O}_5$  supply in the soil. A soil which had the  $\text{P}_2\text{O}_5$  as its min. factor was not in need of P fertilization after 9 years of liming. (4) The vegetation expts. were corroborated by field expts. (5) Weak acid exts. on limed and unlimed podzol soils showed an increased soly. of  $\text{P}_2\text{O}_5$  in the limed soils. (6) Liming seems to increase the soly. of the insol. phosphates of Fe and Al; no exptl. proof was obtained to prove the aforesaid. (7) Liming of podzol soils neutralizes the acidity, increases the absorption properties of the soil, its biological activities, restoring in the same time the fertility of the soil lost during the podzol-soil-forming process. (8) Liming as a means of increasing the N and  $\text{P}_2\text{O}_5$  supply in podzols should be practised. J. S. JOFFE

**Nitrogen and the fertilizer industry.** CHARLES J. BRAND. *J. Franklin Inst.* 207, 665-90 (1929).—An address delivered before The Franklin Inst., in which the nature and importance of N and the development of the art of fertilization are discussed. The processes of manuf. of synthetic N are discussed. In 1913 the world's production of N was 840,055 tons and in 1927 the production capacity of the world was 1,620,000 tons, an increase of almost 100% in 14 years. The production by countries is given. The manuf. of concd. fertilizers and the plan favored by the fertilizer industry for the utilization of the Muscle Shoals plant are discussed. J. J. SKINNER

**Report on nitrogen activity methods in fertilizers. Determination of active water-insoluble nitrogen by the alkaline permanganate method.** JOHN B. SMITH. *J. Assoc. Official Agr. Chem.* 12, 182-91 (1929); cf. *C. A.* 22, 2433.—The effects of the modifications suggested a yr. previously were investigated collaboratively. The results indicated a considerable degree of probability that the results from a single lab. would not differ from the mean for several labs. by more than 3% of that mean. This is not considered the ultimate limit of accuracy for the method, but it should be regarded as encouragement to continue the study of details that allow deviations in technic. A. PAPINEAU-COUTURE

**Report on (the determination of) nitrogen (in fertilizers).** A. L. PRINCE. *J. Assoc. Official Agr. Chem.* 12, 176-81 (1929); cf. *C. A.* 22, 2433.—B. F. Robertson (Clemson Agr. College) has proposed the following unpublished method for the detn. of inorg. N in com. fertilizers in the presence of Ca cyanamide and urea: (1) Det. total N by the usual method. (2) Wash 2 g. of the sample with  $\text{H}_2\text{O}$  to a vol. of 200 cc. and det. N in the residue by any of the modifications of the Kjeldahl method. (3) Distil 50 cc. of the filtrate obtained in (2) with MgO for detn. of ammonia N. (4) Place 50 cc. of the filtrate obtained in (2) in a 500-cc. Kjeldahl flask with 2 g.  $\text{FeSO}_4$  and 20 cc. concd.  $\text{H}_2\text{SO}_4$ , digest for at least 10 mins. after white fumes appear and complete the N detn. as usual. (1) - (2) =  $\text{H}_2\text{O}$ -sol. N.  $\text{H}_2\text{O}$ -sol. N - (4) = nitrate N. (3) + nitrate N = total inorg. N. (1) - inorg. N = org. N. A comparison of this method with the Jones method (*C. A.* 21, 1324) showed the former to be slightly more accurate and simpler. A. PAPINEAU-COUTURE

**Comparative biological and chemical studies in different varieties of stable manure.** G. RUSCHMANN. *Cenir. Bakt. Parasitenk.*, II Abt., 77, 216-39 (1929); cf. *C. A.* 23, 1205.—Manure of various ages and degrees of fermentation was mixed with soil, usually about 10 g. of manure per kg. of soil, and the production of  $\text{CO}_2$  studied. Young, cold fermented samples produced more  $\text{CO}_2$  than did young, warm fermented samples. Old samples in the heated stage held a middle place. JOHN T. MYERS

**Graining and shaping fertilizers.** B. WAESER. *Metallbörse* 19, 285-6 (1929).—To avoid the tendencies to lump and harden upon standing, losses through dusting,

etc., but still to be finely divided enough for proper distribution and absorption in the ground, it is necessary to pay more attention to graining and shaping fertilizers. Sol. fertilizers are thus "grained" or changed to granules of desired sizes, *i. e.*, 1 to 2 mm. diam., by rotary evaporators of the countercurrent type. Satd. solns. may be used to chill superheated brines dropped through sieves into such solns. Hot solns. sprayed into air currents have also proved of value.  $\text{CaCN}_2$  is supplied either in powder or granular form, and Thomas slag always as a powder.

W. C. EBAUGH

**Report on potash.** Direct titration (Weems) method for chlorine in mixed fertilizers. L. D. HAIGH. *J. Assoc. Official Agr. Chem.* 12, 191-3(1929).—Collaborative results on the detn. of Cl by direct titration with  $\text{AgNO}_3$  in the presence of  $\text{K}_2\text{CrO}_4$  of the aq. ext. of mixed fertilizers, some contg. and some without  $\text{NH}_4$  salts, both with and without addn. of  $\text{CaCO}_3$  to neutralize the acidity of the soln., were consistently lower than the theoretical results, but no consistent difference was found that could be attributed either to the acidity of the aq. soln. or to the presence of  $\text{NH}_4$  salts. The consistently low results obtained are possibly due to the fact that part of the chlorides are retained and cannot be recovered by washing with  $\text{H}_2\text{O}$ , as is known to be the case with  $\text{K}_2\text{O}$ .

A. PAPINEAU-COUTURE

**Regulations for the enforcement of the insecticide act of 1910.** Food, Drug and Insecticide Administration, U. S. Dept. Agr. *Service & Regulatory Announcement* I F No. 1, 12 pp.(Oct., 1928).—The text of "An act for preventing the manuf., sale and transportation of adulterated or misbranded Paris greens, Pb arsenate and other insecticides and fungicides and for regulating traffic therein and for other purposes" is given with the regulations adopted.

H. A. LEPPER

**Report on (the electrolytic determination of copper in) insecticides and fungicides.** J. J. T. GRAHAM. *J. Assoc. Official Agr. Chem.* 12, 139-40(1929).—It was found that the tentative A. O. A. C. method for the electrolytic detn. of Cu in such products as Bordeaux-Paris green and Bordeaux-Ca arsenate mixts. without removal of the As and in the presence of  $\text{H}_2\text{O}_2$  gave results checking closely with those of the  $\text{Na}_2\text{S}_2\text{O}_3$  method. If too much  $\text{H}_2\text{O}_2$  is added, the deposition of Cu is slow until the concn of  $\text{H}_2\text{O}_2$  has been reduced by electrolysis.

A. PAPINEAU-COUTURE

**Study with reference to apple canker and to Sphaeropsis malorum.** GIACOMO PRETI. *Ann. scuola agr. Portici* [3], 1, 25-41(1926).—Hanging drop cultures of the conidia of *Sphaeropsis malorum* and of *Macrophoma*, solns. of  $\text{CuSO}_4$ ,  $\text{Al}_2(\text{SO}_4)_3$ ,  $\text{FeSO}_4$ ,  $\text{K}_2\text{S}_2\text{O}_8$  and oxalic acid being used, showed that these arrested germination in the strengths 0.0001, 0.05, 0.06, 0.05 and 0.05%, resp.

ALBERT R. MERZ

**Studies of the relative resistance to arsenical poisoning of different strains of codling-moth larvae.** WALTER S. HOUGH. *J. Agr. Research* 38, 245-56(1929); cf. C. I. 22, 2634.—Colorado larvae consistently demonstrated a marked superiority over Virginia larvae in withstanding poisoning by arsenical sprays.

A. L. MEHRING

**Preliminary report on control of hibernating codling-moth larvae.** L. C. McALISTER, JR. *J. Econ. Entomol.* 22, 424-5(1929).—In preliminary expts. undiluted kerosene and  $\text{C}_2\text{H}_5\text{Cl}$  killed the hibernating larvae of the codling moth (*Carpocapsa pomonella*). Lubricating oil emulsion, nicotine, *m*-nitroaniline, *o*-toluidine, aniline, 2,4-dinitroaniline and nitrobenzene were less efficient.

C. H. RICHARDSON

**Determining hydrocyanic acid gas concentration in fumigation experiments.** C. O. EDDY AND E. N. GEDDINGS. *J. Econ. Entomol.* 22, 366-78(1929).—The following method was used to det. the HCN concn. in a large room fumigated with com. Ca cyanide: Samples of air from the room are passed through a 3.5% NaOH soln., which is then analyzed for HCN by a turbidimetric method modified from the Liebig method for HCN. A standard AgI soln. is freshly prepd. for each series of titrations by diluting 10 cc. 0.1 N  $\text{AgNO}_3$  soln. to 400 cc. with distd.  $\text{H}_2\text{O}$ , adding this soln. with stirring to 400 cc. distd.  $\text{H}_2\text{O}$  contg. approx. 5 g. KI and diluting to 1 l. The soln. of NaOH contg. NaCN is titrated with the standard AgI soln. to the first appearance of turbidity. No consistent difference was noted in the concn. of HCN at different elevations in the room. Temp. and relative humidity did not modify the concn. The rate of decrease of HCN concn. in the room was greater for the higher doses, and was directly proportional to the initial concns. The most rapid change in concn. occurred during the first 5 hrs., but was noticeable throughout the expt. The decrease extended over a somewhat longer period with the higher concns. Smaller doses of Ca cyanide give higher initial concns. of HCN per unit than larger doses.

C. H. RICHARDSON

**Recent progress in the chemistry of derris.** R. C. ROARK. *J. Econ. Entomol.* 22, 378-81(1929).—A review of the chemistry of the active insecticidal principle "rot-enone," from the plant, *Derris elliptica*.

C. H. RICHARDSON

**Maximum weights of various fumigants which can exist in vapor form in a 1000**

**cubic foot fumigating chamber.** R. C. ROARK AND O. A. NELSON. *J. Econ. Entomol.* 22, 381-7(1929).—Formula developed from the equation,  $PV = nRT$ , are presented by which one may derive the no. of lbs. of fumigating gas, liquid, or solid, which can exist in the vapor phase in 1000 cu. ft. space at temps. from 0° to 50°, and 1 atm. pressure. Absorption of the fumigant by the walls of the container or by other materials is not considered. Tables are given for the following compds.:  $NH_3$ ,  $AsH_3$ ,  $CO$ ,  $CO_2$ ,  $SO_2$ ,  $CNCl$ ,  $CH_2:CH_2$ ,  $HCHO$ ,  $CS_2$ ,  $CHCl_3$ ,  $CNO_2Cl_3$ ,  $CCl_4$ ,  $HCN$ ,  $<(CH_2)_2:O$ ,  $CH_2Cl-CHCl_2$ ,  $CHCl_2-CHCl_2$ ,  $CHCl_3$ ,  $CHCl_2-CCl_3$ ,  $HCOO.Me$ ,  $HCOO.Et$ ,  $HCOO.CH(CH_3)_2$ ,  $CH_3-COO.Et$ ,  $CH_2ClCOO.Me$ ,  $pC_6H_4Cl_2$ ,  $C_{10}H_8$ , camphor and nicotine. C. H. R.

**The growth of the foliage and fruit of the apple in relation to the maintenance of a spray coating.** CLYDE C. HAMILTON. *J. Econ. Entomol.* 22, 387-96(1929).—The increase in leaf area and the quantity of  $As_2O_3$  per unit area of leaf surface of apple trees sprayed with  $PbHASO_4$  were detd. at weekly intervals throughout the growing season. The quantity of  $As_2O_3$  upon the fruit was also detd. Methods are described. During the active growing season, much of the reduction in  $As_2O_3$  per unit area is due to the increase in leaf growth; later the loss is largely due to weathering. The reduction in  $As_2O_3$  per unit area or per lb. of fruit largely resulted from increase of growth of the fruit. The loss of  $As_2O_3$  on fruit which was attributed to weathering was much smaller than that which occurred on the foliage. Data are given on the increase in surface area and vol. of apples during growth. C. H. RICHARDSON

**A contribution to the study of control measures for cucumber beetles, *Diabrotica duodecimpunctata* Oliv. and *vittata* Fabr.** H. C. HUCKERT. *J. Econ. Entomol.* 22, 405-11(1929).—The effectiveness of nicotine- $Ca(OH)_2$  dust for the spotted cucumber beetle (*D. duodecimpunctata*) and the striped cucumber beetle (*D. vittata*) depends upon a relatively dry environment, on direct contact of the dust with the beetle and on a heavy application of the dust. Under the same conditions many arsenical and non-arsenical dusts contg.  $Ca(OH)_2$  and  $Ca(OH)_2$  alone were noticeably effective as insecticides. The following compds. were used in the dust mixts.:  $PbHASO_4$ ,  $Ca$  arsenate,  $Zn$  arsenite, Paris green,  $Na_2SiF_6$ ,  $CuSO_4 \cdot H_2O$ , nicotine sulfate and  $Ca(OH)_2$ . C. H. RICHARDSON

**The carrot rust fly problem in New York.** HUGH GLASGOW AND J. G. GAINES. *J. Econ. Entomol.* 22, 412-7(1929).—The carrot rust fly (*Psila rosae*) may be controlled in small plantings by the use of  $HgCl_2$  applied either as a spray or dust.  $HgCl_2$  applied as a spray and  $C_{10}H_8$  applied as a dust were less satisfactory. Mech. barriers are also useful. For large plantings the use of insecticides is not practical. C. H. R.

**New investigations on weed eradication by dusting.** JAQUENAUD. *Compt. rend. acad. agr. France* 15, 611-17(1929).—In most of the cases the weed-eradicating, dusts are preferred to the liquid weed eradicators. It seems equally reasonable to replace the weed eradicators by an eradicating mixt., which at the same time constitutes a complete fertilizer and increases the resistance of the cereals to lodging. Powd. cyanamide, ground sylvite and  $(NH_4)_2SO_4$  play the deciding role in these mixts., and according to the case, one should employ one or the other of the mixts. mentioned for increasing or diminishing the proportion of N according to the requirements. E. F. SNYDER

**Sodium chlorate spray controls quack grass.** C. R. MEGEE AND R. S. HUDSON. Mich. Agr. Expt. Sta. *Quart. Bull.* 11, 129-32(1928).— $NaClO_3$  (1 lb. per gal. of  $H_2O$ ), applied by spraying at the rate of 100-150 gals. per acre early in the season followed by a second application after a few weeks, effectively controlled quack grass. Preliminary results indicate that  $NaClO_3$  has a temporary detrimental effect upon the soil and crop yields for not over 1 season. The use of this chemical is particularly recommended for treating weedy fence rows. Sheep were grazed upon newly sprayed meadow without ill results. C. R. FELLERS

**Agriculture in Germany (DYBS) 2. Rigidity in weak clay suspensions (SCHOFIELD, KEEN) 2. Analysis of caustic poisons (SMITH) 7. Determination of small quantities of the free and organically combined C [in soil] (STROHAL) 7. Nutrition as a factor in the responses of the European corn borer (HOUSER, HUBER) 11L.**

**Apparatus for sterilizing soil by heating.** E. A. FOWLER. Brit. 299,653, Feb. 8, 1928. Structural features.

**Fertilizer.** HENRY H. BASS. Australia 12,453, Mar. 23, 1928. Hot concd. distillery slop is mixed with phosphate material, such as Nauru phosphate rock and  $H_2SO_4$ .  $(NH_4)_2SO_4$  or K salts may be added during the mixing, and the mixt. is dried.

**Fertilizers.** LOUIS NOMBLOT and COMPAGNIE MINIÈRE DU M'ZAITA. Fr. 652,427, April 10, 1928. Natural phosphate is finely ground and treated with the amt. of com. HCl necessary and sufficient to produce total solubilization of the  $H_3PO_4$  and filtered; the filtrate is satd. with free bases or carbonates.

**Fertilizers.** F. UHDE. Brit. 299,896, Nov. 3, 1927. In fixing  $NH_3$  to produce fertilizers, a portion of the  $NH_3$  is oxidized to produce  $HNO_3$  and the latter is used to treat crude Ca phosphate in such proportion that only  $CaCO_3$  contained in it is acted on to form  $Ca(NO_3)_2$ . Residual Ca phosphate is treated with  $H_2SO_4$ ; the  $H_3PO_4$  soln. thus formed is neutralized with  $NH_3$  to form  $NH_4$  phosphate and  $CaSO_4$ ; the latter is acted on by  $NH_3$  and  $CO_2$  to form  $(NH_4)_2SO_4$  and  $CaCO_3$ . Other fertilizer ingredients may be added.

**Mixed potassium and ammonium salts for use as fertilizers.** I. G. FARBERNIND A.-G. Brit. 299,984, Oct. 13, 1927. The solid deposit is sepd. from an aq. soln satd with the chlorides or nitrates or both of K and  $NH_4$ , together with Na salts if desired, and which is in equil. with at least 3 solid phases of the salts; to the sepd. soln there is added solid  $KNO_3$  or  $NH_4NO_3$  or KCl or  $NH_4Cl$  or their mixts., with or without salts of Na or of other metals. Sol. phosphates also may be added to similar solns. to obtain mixed crystals contg. them. Various details and modifications for the production of different mixed crystal products are described.

**Iron compounds.** O. S. NEILL. Brit. 300,233, Aug. 9, 1927. A ferruginous liquor such as a waste pickle or  $FeSO_4$  soln. is dispersed into particles or globules, which are given a rapid rotary motion and exposed to hot drying gases to obtain hollow particles suitable for use in insecticides, for killing weeds, for dehydrating purposes, etc.

## 16—THE FERMENTATION INDUSTRIES

C. N. FREY

**Remarks on the mechanism of alcoholic fermentation.** M. A. J. KLUIJVER. *Bull. soc. chim.* 45, 311-12(1929).—A discussion regarding priority. C. N. FREY

**A new theory of the mechanism of alcoholic fermentation.** A. J. KLUIJVER. *Bull. trimestr. assoc. élèves école sup. brasserie univ. Louvain* 29, 1-16(1929).—An address outlining the work of K. and co-workers (*C. A.* 19, 2353, 2967, 3510; 20, 930; 21, 108, 2908; 22, 245, 1168, 1785; 23, 619), which led them to a conception of the mechanism of alcoholic fermentation in which the formation of hexose-monophosphoric ester and oxido-reduction reactions play the most important part, as follows:

**Obtaining glycerol by fermentation.** A. ULLRICH. *Metallbörse* 19, 509-10, 621-2(1929).—A review. A. PAPINEAU-COUTURE  
W. C. ÉBAUGH

**The acetone-butyl fermentation and its application to molasses.** G. MEZZADROLI AND G. MAGNO. *Giorn. chim. ind. applicata* 10, 551-4(1928).—With the use of *Bacillus butylicus*, sugars derived from the starches (cereals, potatoes, etc.) or molasses, may be fermented,  $(CH_3)_2CO$  and  $C_4H_9OH$  being produced simultaneously. *Concns. of*

5 6% sugar, and in molasses  $p_H = 6$  to 5.4, are optimum conditions. Whether molasses or grains are used will depend on the relative costs. A. W. CONTIERI

The higher-boiling constituents of a Yugoslavian fusel oil. I. The basic constituents. A. CHASTON CHAPMAN AND F. A. HATCH. *J. Soc. Chem. Ind.* 48, 97T-100T (1929).—A study has been made of the basic constituents of a high-boiling fraction obtained from a com. fusel oil made from molasses. The bases consist chiefly of trimethylpyrazine and tetramethylpyrazine. Two bases isomeric with tetramethylpyrazine, possibly ethylpyrazine, were found. Higher homologs were present. One had the formula  $C_8H_{13}N_2$ , a substance apparently not described previously. A compd. considered to have the compn.  $C_{10}H_{15}N_2$  was studied. Pyridine was not found nor collidine nor 2,5-dimethyl-3-ethylpyrazine. C. N. FREY

Experiments on the separation and washing of spent grain from wort by decantation. J. KAUX. *Brasserie et malterie* 19, 21-8(1929).—The expts. showed that sepn. by decantation is impractical because of the large amt. of ext. remaining with the spent grain and the time required for settling. A. PAPINEAU-COUTURE

Agitation in fermentation. P. PETIT. *Brasserie et malterie* 19, 33-7(1929).—A brief discussion of the effects of "rousing" and other methods of agitation on the danger of infection, on the degree of fermentation and on the "body" of the finished beer. A. PAPINEAU-COUTURE

Rapid determination of moisture in the malting industry. P. PETIT. *Brasserie et malterie* 19, 43-6(1929).—The Chopin app. consists essentially of a small thermostatically controlled elec. oven, in which a 20-g. sample is heated in a metal tube connected to a small condenser and delivering into a suitably graduated receiver, the %  $H_2O$  being read directly after 20 mins. heating. The results obtained agree within 1 5% with those obtained by heating in a paraffin bath or by drying to const. wt. at 105°. A. PAPINEAU-COUTURE

Determination of alcohol in wines and liquors by means of potassium dichromate and sulfuric acid. L. SEMICHON AND M. FLANZY. *Ann. fuls.* 22, 139-52(1929).—After a discussion of the various chem. methods of detg. EtOH, detailed results are given of an investigation of the  $H_2SO_4$ - $K_2Cr_2O_7$  method, which showed that it is as accurate as (if not more accurate than) the official French method by means of an alcoholometer. The following technic is recommended: to 20 cc. of unneutralized wine in a 100-cc. flask add about 30 cc. distd.  $H_2O$ , distil about half the liquid into a 100-cc. volumetric flask, make to 100 cc. at 15°, in an Erlenmeyer flask, mix. 20 cc. of standard  $K_2Cr_2O_7$  (33.832 g. per l., 1 cc. = 0.7943 mg. EtOH = 1% EtOH by vol.) and 10 cc. of 66° Bé.  $H_2SO_4$ , cool, add all at once 5 cc. of the distillate, stopper, after 5-10 mins. titrate the excess of  $K_2Cr_2O_7$  with ferrous  $NH_4$  sulfate (135.310 g. and 20 cc.  $H_2SO_4$  per l.) using 1%  $K_3Fe(CN)_6$  as outside indicator. Under the above conditions oxidation of EtOH to AcOH is complete and there is no loss of AcH by volatilization. A. PAPINEAU-COUTURE

Wine clarification. M. RÜDIGER AND E. MAYR. *Kolloid-Z.* 47, 141-55(1929); cf. C. A. 22, 4713.—In a study of the clarification of wine by use of gelatin, no relation was found between the constituents of the wine and the clarity obtained. This is particularly true with respect to tannic acid content. No conclusion can be made regarding the type of gelatin to be used, for clarification is affected by the time of swelling of the gelatin up to 18 hrs., the temp. and the concn. employed. A 0.25% soln. which has been aged 2-3 days before adding gave optimum results. The inefficiency of greater concns. is believed due to formation of secondary particles. Temps. between 30° and 40° are optimum. A zone of clarity is found with respect to gelatin content and  $p_H$  of the wine. Too much gelatin increases the N content of wine. The viscosity decreases and surface tension increases with increasing gelatin content. The possibility of treating overclarified wine with agar is considered. A new method of treating viscous wines with agar is given. The pptn. of the tannin-gelatin material is only a secondary reaction. RAYMOND H. LAMBERT

Nature of the substance causing bitterness in wines. E. VOISENET. *Compt. rend.* 188, 941-3(1929); cf. C. A. 4, 2709, 3117; 5, 3606.—Previous work by the author has demonstrated the formation of acrolein during those disorders which cause bitterness of wines. This aldehyde presumably undergoes resinification to form the bitter principle. In an effort to concentrate this substance, 40 l. of wine was submitted to a series of fractional distillations and ether extrns. About 3 cc. of a liquid boiling at 198° was obtained. This sirupy liquid has a faint odor of acrolein, is extremely bitter and yields acrolein on careful oxidation. R. P. WALTON

The disease of stringiness in wines. G. MEZZADROLI AND E. VARETON. *Giorn. chim. ind. applicata* 11, 14-7(1929).—Wines which are turbid and oily may be cured

by bubbling through  $\text{SO}_2$  till the acidity is increased by 2 cc. 0.1 N NaOH per 10 cc. of wine. This clarifies the wine but the oiliness remains. Now activated carbon (Norite) is added (1% by vol.) and the wine stirred vigorously, and filtered, and the norite treatment repeated. This restores the wine as well as removes all but a trace of the  $\text{SO}_2$ . A. W. CONTIERI

**Interpretation of the results of analysis of damaged wines.** L. ROOS. *Ann. fals.* 22, 166-9(1929).—The analytical results obtained with wine which has been attacked by *Mycoderma aceti* might lead to the conclusion that the wine has been watered if the history of the product is not known. A. PAPINEAU-COUTURE

**Cognac brandy, its production and handling.** BENGT THORBJÖRNSSON. *Tek. Tid., Uppl. C (Kemi)* 58, 81-7(1928).—Cognac is defined as the natural product obtained by distn. without rectification of wine which is cultured, treated and distd within the borders of the Cognac district in France, the borders having been fixed by French law (1909). The article contains an illustrated description of the production, storing and handling of this product. C. A. ROBAX

**Study of the limit of fermentation (of beer).** PH. LECOCQ. *Bull. assoc. élèves inst. sup. fermentations Gand* 30, 125-35(1929).—The paralyzing action of the medium (EtOH content and acidity) on the elimination of the last traces of fermentable sugars has been confirmed, the action varying with different strains of yeast. Differences in the degree of fermentation with different yeasts, even with 3 successive fermentations, are possibly due to the time factor, which was not investigated. A. P.-C.

**Determination of carbon dioxide in beer by titration.** J. DE CLERCK. *Bull. trimestr. assoc. élèves école sup. brasserie Univ. Louvain* 29, 30-7(1929).—The method worked out is a modification of that of J. Cannizaro (*Am. Brewer* 41, 33(1924)) in which the beer is added to an excess of 0.2 N  $\text{Na}_2\text{CO}_3$  and the excess titrated with 0.2 N HCl, correction being applied for the non-volatile acids. The modifications comprise reading the end point by means of Liérs' method (*C. A.* 15, 2149) and using NaOH instead of  $\text{Na}_2\text{CO}_3$ . As this requires titration to a  $p_H$  value of 8.4 in order that the  $\text{CO}_2$  will be converted to  $\text{NaHCO}_3$ , a buffer soln. of this  $p_H$  is prepd. by adding 8.5 cc. 0.2 N NaOH to 50 cc. of a 0.2 N  $\text{H}_3\text{BO}_3$  and KCl soln. (12.404 g.  $\text{H}_3\text{BO}_3$  and 14.912 g. KCl per l.) The technic is described in detail. A. PAPINEAU-COUTURE

**Top fermentation by means of pure yeast cultures.** R. MORLION. *Bull. assoc. élèves inst. sup. fermentations Gand* 30, 55-75(1929).—Exptl. fermentations made with pure cultures prepd. from commercial brewers' yeast gave good results, the beer being easy to clarify and resistant. The use of raw grain resulted in degeneration of the yeast, particularly when used to the extent of 50%. A. PAPINEAU-COUTURE

### Cereal chemistry. III. The basic materials (FAIRBROTHER) 12.

**Fermentation.** I. G. FARBENIND. A.-G. Fr. 652,407, Apr. 10, 1928. In fermentation processes, particularly for the production of BuOH, the products are distd off in vacuum before completion of the fermentation, fresh wort is added and the fermentation continued.

**Fermentation.** DEUTSCHE HYDRIERWERKE A.-G. Fr. 652,556, Apr. 3, 1928. Natural mixed cultures of yeast or bacteria, with or without submission to one or more selection processes, are used in fermentation processes. The selection process may consist in cultivating the yeast, etc., in the presence of the product to be produced. Thus, yeast for the production of alc. is cultivated in the presence of alc.

**Tartaric compounds.** ALPHONSE L. NEMOZ. Fr. 651,690, Feb. 14, 1928. Lees in the form of boiling vinasses are centrifuged to ext. the tartaric compds. The molten liquors always kept at the same temp., so that they always contain the same amt of bitartrate in soln., are treated with HCl and then satd. with  $\text{CaCO}_3$ , the tartrate being dried.

**Clarification of wine, fruit juices, etc.** HERMANN LIST. Fr. 652,144, Apr. 4, 1928. The liquid is clarified in a rotating cylinder, the heavy particles adhering to the walls, and then filtered in a centrifuge.

## 17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

The importance of grinding seeds in the manufacture of coriander and anise ethereal oils. A. CHERNUKHIN. *Masloboino Zhirnooe Delo (Oil and Fat Ind.)* (Russia) 1928, No. 5, 11-13.—An increase in the yield of 17 and 5% in coriander and anise

oils, resp., was obtained by steam-distg. the ground seed, while 10 to 15% less steam and 25% less time were required for these operations. A. A. BOEHTLINGK

**Comparative tests of chlorine disinfectants.** R. FETSCHER. *Z. Desinfekt. u. Gesundh.* 20, 78(1928); Dept. Sci. Ind. Research. Water Pollution Research Board *Summary of Current Lit.* 2, No. 6, A146(1929).—F. made tests with *B. coli* of the following disinfectants: Chloramine, "Pantosept" I, II, III, "Pantosept" Tablets I and II, "Pantosept" Soda Tablets, "Pantosept" Soap, "Caporit," "Maquocid," chloride of lime and cresol soap, to det. the relationship between the Cl content and the disinfecting power. The Cl contents of the different preps. were widely different. The efficiency was not proportional to the Cl content. Alterations in the Cl content of any one prep. lead to corresponding changes in bactericidal properties. Chloramine-Heyden, containing about 24% of active Cl, has the same disinfectant properties as Caporit, contg. about 60%. Magnocid is the next most efficient, with 40% of active Cl, and the "Pantosept" preps. show great variations in their Cl content and disinfecting properties. "Pantosept" Soda Tablets and "Pantosept" soap cannot be used as disinfectants. E. J. C.

**Nitrobenzaldehyde as a reagent for organic drugs.** H. W. VAN URK. *Pharm. Weekblad* 66, 429-35(1929).—A large no. of org. compds. give color reactions with *o*-, *m*- and *p*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>CHO. The reagent consists of a 1% soln. of the aldehyde in EtOH contg. 2% H<sub>2</sub>SO<sub>4</sub>. A few drops of this is added to a trace of the substance to be tested, the mixt. is evapd. on the water bath and the residue dissolved in H<sub>2</sub>O. The colors thus obtained range from yellow to violet. In general, the reaction is pos. with phenols, phenetidines, pyrroles, some CO derivs. and alkaloids contg. OH; neg. with anilides, purines and pyridines. Salicylic acid, *p*-cresol, holocaine,  $\beta$ -naphthol, acoune, scopalamine, narcotine and tyrosine react with *o*- but not with *m*- or *p*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>CHO. Morphine and codeine may be distinguished by the green to brown color obtained with the former and the yellow color with the latter. A list of 112 substances is given and the colors obtained with *o*-, *m*- and *p*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>CHO are tabulated separately. Reactions, which might be useful for purposes of identification, are designated by italics. A. W. DOX

**An impurity in commercial narceine which gives the color reaction with sodium nitroprusside.** J. J. L. ZWIKKER. *Pharm. Weekblad* 66, 445-9(1929).—Some samples of com. narceine give a red color with Na nitroprusside, while others give only a yellow color. The red reaction is due to the presence of a small quantity of methylnarceine, and may be obtained with pure narceine after treatment with Me<sub>2</sub>SO<sub>4</sub>. It appears that com. narceine is frequently prepd. by methylation of narcotine, and in this process a small portion of the product becomes further methylated to methylnarceine. The nitroprusside reaction will detect 2% of methylnarceine in 50 mg. of narceine-HCl. Narceine samples may contain more or less Me deriv. and still conform to the present Pharm. standards. A. W. DOX

**[Standardization of] preparations containing ergotamine.** H. J. STROBAND. *Arch. intern. Pharmacodynamie* 34, 224-6(1928); *Physiol. Abstracts* 13, 476.—Expts. for the detn. of ergotamine by measuring its antagonism for adrenaline have been made to find a more suitable organ than the uterus of the guinea-pig, from which the alkaloid is not easily washed out. The uterus of the ox, hedgehog and pig, as well as the vagina and vas deferens of the pig, have been examd. and are not any better, if as good, for the purpose. H. L. D.

**Application of "critical solution temperature" to pharmaceutical investigations.** F. WRATSCHKO. *Pharm. Presse* 34, 143-5(1929).—In connection with a discussion of the possible use of the "critical solution temperature" in the examn. of pharmaceutical preps., the following values were detd. for the pairs: Et<sub>3</sub>N—H<sub>2</sub>O 18.6, butyric acid—H<sub>2</sub>O 24.3, CS<sub>2</sub>—MeOH 40.5, C<sub>6</sub>H<sub>14</sub>—MeOH 42.8, C<sub>2</sub>H<sub>4</sub>(CN)<sub>2</sub>—H<sub>2</sub>O 55.4, PhOH—H<sub>2</sub>O 68.8, AcC<sub>2</sub>H<sub>5</sub>Ac—H<sub>2</sub>O 87.7, salicylic acid—H<sub>2</sub>O 90.5, iso-BuOH—H<sub>2</sub>O 107, *m*-nitrobenzoic acid—H<sub>2</sub>O 107, resorcinol—C<sub>6</sub>H<sub>6</sub> 108.9, EtCN—H<sub>2</sub>O 113.5, BzOH—H<sub>2</sub>O 115.5, PhCl—S 117, furfural—H<sub>2</sub>O 122.8, PhCNS—S 125.7, iso-BuOH—H<sub>2</sub>O 131.5, PhNH<sub>2</sub>—S 139.5, AcEt—H<sub>2</sub>O 150, C<sub>6</sub>H<sub>6</sub>—S 162.8, PhNH<sub>2</sub>—H<sub>2</sub>O 167, PhMe—S 179.5°. W. O. E.

**Alkaloidal constituent of *Artabotrys suaveolens* Blume.** JOAQUIN M. MARAÑON. *Philippine J. Sci.* 38, 259-68(1929).—The bark of the stem and root of *A. suaveolens* Blume from the Philippines contains an alkaloid, *artabotrine*, C<sub>23</sub>H<sub>35</sub>NO<sub>6</sub>, m. 187°. It has a slightly bitter taste, is physiologically active, freely sol. in CHCl<sub>3</sub>, fairly sol. in Et<sub>2</sub>O, EtOH and AcMe; it is sparingly sol. in other org. solvents. It is pptd. by the usual alk. reagents, gives color tests with concd. HNO<sub>3</sub>, Fröhde's reagent and some

oxidizing agents. The *HCl* and *HBr* salts occur in definite crystal forms (illustrated).  
W. O. E.

**Histological and microchemical studies on the bark and leaf of *Artabotrys suaveolens* Blume from the Philippines.** JOSÉ K. SANTOS. *Philippine J. Sci.* **38**, 269-82 (1929).—The structure of *A. suaveolens* is described in detail. Microchem. tests proved that the alkaloid of *A. suaveolens* is located in the stem and root barks and is lacking in the wood and the leaf. It is found in the cortical parenchyma, the medullary cells and the phloem parenchyma. It is relatively more abundant in the cortical parenchyma than in the other types of tissues, and there is a greater amt. of alkaloid in the root bark than in the stem bark.  
W. O. E.

**Chaulmoogryl-substituted phenols and ethyl chaulmoogryloxybenzoate.** IRENE DE SANTOS AND AUGUSTUS P. WEST. *Philippine J. Sci.* **38**, 293-8 (1929).—Four new esters of chaulmoogric acid were prepd.: *2,4-dichlorophenyl*,  $C_{24}H_{33}O_5Cl_2$ , crystals, m. 53.1-55.1°; *2,4-dibromophenyl*, crystals, m. 57.2-60.2°; *hydroquinone ester*,  $C_{24}H_{33}O_5$ , crystals, m. 54.1-57.2°; *m-carbethoxyphenyl*,  $C_{27}H_{40}O_5$ , m. 56.1-59.1°. All 4 esters are sol. in the common org. solvents.  
W. O. E.

**Oxytocin and vasopressin.** A further examination of the separated principles of pituitary (posterior lobe) extract. J. H. BURN. *Quart. J. Pharm.* **1**, 509-12 (1928).—The anti-diuretic activity of a sample of vasopressin was found to be the same per unit of pressor activity as that of a sample of pituitrin. No trace of anti-diuretic activity was found in a sample of oxytocin. The power which pituitary extract possesses of inhibiting the hypoglucemic effect of insulin is possessed also by vasopressin but not by oxytocin.  
W. O. E.

**Variation in activity of different samples of strophanthin.** FRANK WOKES. *Quart. J. Pharm.* **1**, 513-6 (1928).—From time to time complaints are made concerning the activity of samples of strophanthin. Nine different com. samples were accordingly examd. in comparison with the official ouabain of the U. S. P. X. by the cat method. The strongest had 2.4 times the potency of the weakest. The av. potency of 8 of the samples was 47.3% of that of ouabain, and 7 of the 8 were within 25% of this av. It is suggested that a sample of strophanthin should not be regarded as satisfactory for medicinal purposes if it differs from this av. by more than 25%. The 9th sample of strophanthin possessed only  $\frac{1}{2}$  the av. potency of the other samples.  
W. O. E.

**Use of rabbits in insulin assay.** KATHLEEN CULHANE. *Quart. J. Pharm.* **1**, 517-33 (1928).—The error of a cross-test in which 10 or more selected rabbits are used is less than 5%. For the best results the wts. of the 2 groups of rabbits should be equal. Certain rabbits are unsuitable for quant. work on insulin. Variability of response is affected by wt. and by season, heavy animals giving a higher % reduction than light ones, and all being more sensitive in the summer than in the winter. An alternative method is suggested for the calcn. of cross-test results in which a "day variation factor" is formulated. The "day variation" for groups of rabbits is discussed, and a new method of assay suggested, which is less accurate but quicker than a cross-test. The effect on the result of terminating a cross-test at the 2nd and 3rd hr. has been shown to be small.  
W. O. E.

**Structure of synthetic drugs in relation to their therapeutic action.** W. H. LINNELL. *Quart. J. Pharm.* **1**, 558-73 (1928).—A review.  
W. O. E.

**Recent research in pharmacognosy.** T. E. WALLIS. *Quart. J. Pharm.* **1**, 571-80 (1928).—A review.  
W. O. E.

**Standardization of tincture of digitalis.** FRANK WOKES. *Quart. J. Pharm. and Pharmacol.* **2**, 48-62 (1929).—The requirements laid down for tincture of digitalis in the present edition of the Brit. Pharm. are unsatisfactory. They assume that digitalis leaves always have approx. the same activity. But when 8 samples of English digitalis leaves were assayed by the cat method, they showed an av. activity similar to that possessed by the international standard, but a variation in activity between different samples of nearly 140%. This variation in activity of digitalis leaves leads to a similar variation in the activity of tincture of digitalis. Among 80 com. samples of the tincture a variation in activity of nearly 400% was noted, 25 of the samples differing by more than 25% from the activity possessed by a tincture prepd. from the international standard powder. This variation in activity of the com. tinctures can at present be avoided only by employing biological assays. Twenty samples of tincture of digitalis were biologically assayed both by the cat and by the frog method. The av. exptl. errors were 8.7 and 5.9, resp. The results by the 2 methods differed from each other by more than the exptl. error in 7 cases. On the whole, the frog method gave lower results than the cat method. When the age of these tinctures was taken into account, the cat and frog results became consistent. It was found

that the frog potency diminishes rapidly and steadily during the 1st few months of storage, until it reaches a level of  $1/2$  to  $1/3$  of its original value, at which point it becomes fairly const. for some yrs. The cat potency, on the other hand, decreases much more slowly. Tinctures not more than a month old will give the same results when assayed either by the cat or by the frog method. With older tinctures, the results will be different, and further clinical evidence is required to show which is the more accurate est. of the therapeutic value. If the frog method is to be employed, comparison must in every case be made with a standard tincture which has not been made longer than a month.

Science and technic in service of the practical druggist. K. H. BAUER. *Pharm. Zentralhalle* 70, 309-17(1929).—An address.

W. O. E.

Alkaloidal content of ipecacuanha infusion. G. BRUCK. *Apoth. Ztg.* 44, 612 (1929).—Infusions of 2-g. samples (total alkaloids 0.047%) in 800, 400, 200, 100 and 40 g. H<sub>2</sub>O yielded 0.029, 0.019, 0.0186, 0.0169, 0.0168% alkaloid, resp., while addn. of HCl to the  $2/40$  infusion raised the alkaloid content to 0.0338%.

W. O. E.

Synthetic aromatic chemicals. J. N. TAYLOR. *Am. J. Pharm.* 101, 345-61 (1929).—The products of this branch of the org. chem. industry are not now arbitrarily restricted to cyclic compds., but include those of aliphatic origin as well. Synthetic aromatic chemicals are employed primarily because of their pleasant odor or agreeable flavor and may be classified chemically as alcs., ketones, aldehydes, acids and esters of both coal-tar and non-coal-tar origin. In addn. to the utility of these synthetic org. compds. as perfume bases and flavor materials they are also employed in many other ways. A classified list describing some of the more important synthetic aromatic chemicals finding employment in various ways is given. Tables are given showing U. S. production of coal-tar flavor and perfume materials for each year from 1918 to 1927, inclusive, imports into the U. S. of principal aromatics entered for consumption for each year from 1924 to 1928, inclusive, and also a table including production of synthetic aromatics compared with imports during 1926 and also 1927.

W. G. GAESSLER

The evaluation of solutions of adrenaline. TOM. VACEK. *Časopis Českoslov. Lékařnictva* 9, 1-3(1929).—In a study of the influence of acidity of aq. solns. of adrenaline it was found that the more acid solns. were not always more stable and that the stability does not increase in proportion to the degree of dissocn. of the acid used.

WILLIAM J. HUSA

Determination of the oxidizability of adrenaline. TOM. VACEK. *Časopis Českoslov. Lékařnictva* 9, 3-4(1929); cf. *C. A.* 22, 1652.—The stability of aq. solns. of adrenaline can be estd. by detg. the oxidizability, using H<sub>2</sub>O<sub>2</sub> and following the change colorimetrically.

WILLIAM J. HUSA

Belladonnine, bellatropine and chlorotropane. MAX and MICHEL POLONOWSKI. *Bull. soc. chim.* [4], 45, 304-11(1929).—The literature on bellatropine (I) is reviewed. Many errors have occurred in the literature concerning this substance; in order to clarify them, the following work was undertaken. It was found that bellatropine, supposedly an isomer of tropine (II), is really chlorotropane. Crude I was prepd. from atropine (III) hydrobromide and Ba(OH)<sub>2</sub>, converted into the *chloroplatinate*, m. 252°, or the *chloroaurate*, m. about 160° (sinters above 150°), and pure I obtained from these derivs. by means of H<sub>2</sub>S. Upon hydrolysis it yields II and a polymer of atropic acid. Treatment with HCl produces 3-chlorotropane (IV) hydrochloride, m. 232-3°. IV is a colorless oil, b. 163-5° with decompn. partially to the hydrochloride of tropidine (V). From IV there was prepd. the *chloroplatinate*, m. 227-8°, the *chloroaurate*, m. 215°, *picrate*, m. 216-7°, *MeI deriv.* (VI), m. 305-6° and the *oxide*, the hydrochloride of which m. 210° and the *picrate* m. 174-5°. Reduction of VI yields the *MeI deriv. of tropane*. The action of HCl on atropine, III and hyoscyamine and II produces IV-HCl in every case. Similarly, treatment of I and III with HBr yields 3-bromotropane, the *picrate* of which m. 205°. The *picrates* of II, pseudotropane and V m. 228°, 258° and 285°, resp.

J. M. LEVINE

Methyl red as an indicator for determination of several alkaloids. E. M. EDERMAN. *Farm. Zhur.* 1928, 602-6.—A volumetric detn. of hydrastine and quinine was made and the results agreed closely with those of the gravimetric method. Methyl red as an indicator gives a very clear end-point and should be preferred to methyl orange or hematoxylin.

YETTA POROSOWSKY

"Calcas," a casein preparation to replace laroson. E. I. VALIASHKO AND N. A. VALIASHKO. *Farm. Zhur.* 1928, 699-702.—Calcas (Ca caseinate) was prepd. and compared with laroson of the firm Hoffmann-La Roche. The data indicate that the 2 compds. are practically identical. Calcas has the advantage of being more easily

sol. Its physiol. action is satisfactory and the prepn. from milk does not require a special app.

**A simplified method of preparing a solution of iron albuminate.** I. A. OBERHARD *Farm. Zhur.* 1928, 702-5.—A soln. of Fe albuminate was prepd. by mixing dil. solns. of  $\text{FeCl}_3$  and albumin at a temp. of  $50^\circ$  and neutralizing the mixt. with a 15% soln. of NaOH at the same temp. After the ppt. was washed free of Cl and dissolved by making slightly alk. the other components which the pharmacopoeia prescribes (glycerol, alc., etc.) were added. The prepn. is stable and satisfies the requirements of the pharmacopoeia.

**The aloe in Sardinia.** G. B. ZANDA. Univ. Cagliari. *Boll. chim. farm.* 68, 255-60 (1929).—Notes on the occurrence of different *Aloe* species in Sardinia. The characteristics of the juices obtained from some species are discussed.

**Cod-liver oil with ferrous iodide.** G. SIBONI. *Boll. chim. farm.* 68, 260-1 (1929). Formulas are given for the manuf. of cod-liver oil contg.  $\text{FeI}_2$ .

**Comparative study of methods of determination of citral in lemon essence and characteristics of Spanish essence.** O. FERNÁNDEZ AND A. MOSCARDÓ. *Anales de la Real Soc. españ. fís. quim.* 27, 265-78 (1929).—The best method is that of the U. S. Pharm. The citral content of Valencian essence is shown.

**Tegin, a new base for cosmetics.** A. KARSTEN-SALMONY. *Mat. grasses* 21, 8484 (1929).—Tegin is an ester giving emulsions readily with  $\text{H}_2\text{O}$  at  $70-80^\circ$ . The consistency of the emulsions can be regulated by altering of the amt. Tegin. S. suggests possible uses for this product. Also in *Chem.-tech. Rundschau* 44, 47 (1929).

**Scarlet R, aminoazotoluene and acetoazotoluide as cicatrizing agents.** ED. JUSTIN-MUELLER. *J. pharm. chim.* [8], 8, 441-9 (1928).—An indication of the efficacy of the dye-stuffs named as cicatrizing agents for wounds may be obtained by the behavior *in vitro* of mineral-oil solns. of these dyes (0.1 g.: 10 cc.) when shaken with aq. solns. of ovalbumin (1 egg-white: 1 l.) or blood albumin (0.5 g.: 1 l.). Stable emulsions are formed whether the dyes are present or absent. When the emulsion is filtered and the paper is dried, it is covered with a perceptible, smooth film only if the dyes were used; in a blank test film formation (parallel to cicatrization), is insignificant. The film is more accentuated and better formed with acetoazotoluide (azodermine Agfa) (A), than with Scarlet R, a fact in accord with previous clinical observations. The emulsions formed with or without addn. of the dyes remove 50% of ovalbumin from the aq. soln. used, nil from the blood albumin soln. except that in the case of A, 25% of blood albumin is also removed. In the formation of the film, the dyes seem to act as peptizing agents on the proteins (cf. C. A. 15, 2372; 16, 368). Of the dyes tried, A is not only innocuous, as compared with aminoazotoluene, it also produces only a faint, or practically no annoying, coloration.

**Purification of vaccine virus by adsorption on kaolin.** HIDETAKE YAOI AND HISAO KASAI. *Proc. Imp. Acad. (Japan)* 5, 179-81 (1929).—The virus of vaccinia is adsorbed on kaolin in neutral or, more completely, in weakly acid reaction. Washing causes no, or very slight, diminution of the virus and the disoccn. of the virus from kaolin takes place very readily in strong alk. solns. The vaccinal prepn. is usually a transparent soln. and contains no cell or cell elements. The prepn. show weak biuret reaction when concd. to 0.1 of the original vol., but the Molisch reaction is neg.

tical Perfumery. 3rd ed., revised and enlarged. London: Chapman & Hall, Ltd. 535 pp. 25s. net. Cf. C. A. 23, 3051.

**Medicine for treating diseases of the biliary tract.** EMANUEL W. LIPSCHUTZ. (to Brooklyn Scientific Products Co.). U. S. 1,714,430, May 21. Oleic acid and bile salts are used together.

**Cancer toxin, antitoxin, etc.** T. J. GLOVER. Brit. 300,144, May 6, 1927. Cancer organisms (the properties of which are described) are prepd. from cancerous tissue in a medium consisting of decoctions of sunflower seed, Iceland moss, and Irish moss, peptone, hormone gelatin broth and glucose, with or without agar, of a  $p_H$  about 6.5. Toxins and antitoxins are prepd. from the cultures. The "hormone gelatin broth" is made from eggs, beef heart, peptone, NaCl, digested beef heart, gelatin and dextrose.

**Depolymerizing carbohydrates such as starch and cellulose by treatment with ethylene glycol and monochlorohydrin.** FRITZ LANGE (to I. G. Farbenind. A.-G.). U. S. 1,714,565, May 28. Cf. Brit. 290,377 (C. A. 23, 981). The products are suitable for pharmaceutical purposes.

**Freezing bio-colloids.** BORIS ZITOVITSCH. Fr. 652,234, Apr. 5, 1928. Bio-colloids such as therapeutic serums, toxins, fruit juices, pharmaceutical extracts, beer, milk, cream, etc., are frozen by introducing them in a fine mist or in small drops into a chamber the temp. of which is below the m. p. of the liquid. The colloids may be restored to the original state without detriment when desired.

**Dialkoxyacridines.** LOUIS BENDA and WERNER SCHMIDT (to Winthrop Chemical Co.) U. S. 1,715,332, May 28. Dialkoxyacridines are formed by heating 3,6-dihydroxyacridines in the presence of acid-binding substances, with alkylating agents. 3,6-Diethoxyacridine m. 142-3°; 3,6-dimethoxyacridine m. 138-9°; and 3,6-bishydroxythoxyacridine m. 200°. These compds., of which the dimethoxy compd. is particularly mentioned, have been found suitable for combating diphtheria bacilli and streptococci even when highly dil.

**Cyclopentyl compounds having bactericidal properties.** ROGER ADAMS (to Abbott Laboratories). U. S. 1,715,052, May 28. Compds. which in general are strongly bactericidal against acid-fast bacteria such as *B. leprae* or *B. tuberculosis* and which have the general formula  $C_5H_9(CH_2)_yCHRCOOZ$ , in which "y" represents zero or more, R represents an aliphatic hydrocarbon group, and Z represents H, a metal, or a hydrocarbon group such as an alkyl or an alkylene, are made by a process which includes introducing an alkyl group and a group contg. a cyclopentyl radical into a malonic ester, followed by saponification and elimination of one mol. of  $CO_2$ . The compd. of the general formula  $C_5H_9CHRCOOH$  in which  $R = C_8H_{17}$   $b_1$  165°;  $R = C_9H_{19}$   $b_1$  177°, m. 40-2°;  $R = C_{10}H_{21}$   $b_1$  176°, m. 37°;  $R = C_{11}H_{23}$   $b_1$  175°, m. 48°. The compd. of the general formula  $C_5H_9CH_2CH_2CHRCOOH$  in which  $R = C_8H_{17}$   $b_2$  130-2°;  $R = C_9H_{19}$   $b_1$  135-7°;  $R = C_7H_{15}$   $b_2$  152-4°;  $R = C_8H_{17}$   $b_1$  173-5°.

**Dry yeast.** MATRO GES. Brit. 300,039, Dec. 24, 1927. In prep. dry yeast for curative and nutritive purposes, from fresh moist yeast, the yeast is subjected to extn. with ale at a temp. of 55-65°, followed by pressing, washing, drying and heating at 150-160°.

**Disinfectant.** THEODOR SABALITSCHKA and HEINRICH JACOBSON. U. S. 1,715,251, May 28. An ester of a non-adjacent hydroxybenzoic acid is used for disinfecting the mouth, etc.

**Chewing gum.** HOWARD W. MATHESON (to Can. Electro Products Co., Ltd.). Can. 289,982, May 28, 1929. A compn. of matter for use as chewing gum includes chiclet and sweetening and flavoring material and a product made by the treatment of vinyl acetate with a satd. aliphatic aldehyde. Cf. C. A. 22, 3026.

## 18—ACIDS, ALKALIES, SALTS AND SUNDRIES

E. M. SYMMES

**The manufacture of synthetic nitric acid.** M. KALTENBACH. *Chimie & industrie* 21, 701-7 (1929).—Transportation of liquid  $NH_3$  by common carriers is expensive because of the precautions required to meet the regulations. A system is described, suitable for transportation over short distances or over private lines when the  $NH_3$  and  $HNO_3$  plants are close to each other, in which the  $NH_3$  is cooled to -30° and transported in ordinary tank cars covered with suitable insulation. The loading and unloading plants are also described. The Parsons catalyzer, consisting of 3 thicknesses of Pt gauze

in the form of a hollow cylinder, has been improved by adding a fourth layer of gauze on the outside, which increases very greatly its mech. strength, the outer layer taking practically no part in the catalysts and consequently deteriorating very slowly. It also permits passing the  $\text{NH}_3$  through the catalyzer at a higher rate, thus increasing the output of the catalyzer. By using a portion of the catalyzed gases to heat the  $\text{NH}_3$  gas, the amt. of catalyzed gases thus used being regulated by a by-pass, the temp. in the catalyzer is readily kept at the optimum pt. (about  $1000^\circ$ ). Various features of the construction of the absorption towers, designed to improve the efficiency of the absorption of the catalyzed gases, are described briefly. A. PAPINEAU-COUTURE

**Progress in the manufacture of sulfuric acid in recent years.** II. ST. ZEROMSKI. *Przemysl Chem.* 13, 106-11 (1929); cf. C. A. 23, 934.—A review and bibliography of the catalytic oxidation of  $\text{SO}_2$  in the presence of oxides of N. A. C. ZACHLIN

**Carbamate-carbonate theory of the ammonia-soda process.** E. I. ORLOV. *Ukrainskii Khem. Zhur.* 3, Tech. Pt. 139-40 (1928).—O.'s article (the physico chem side of the ammonia-soda process and in particular of the working of the carbonization tower, *Ukrainskii Khem. Zhur.* 1, (1928)) was a result of an application of Fenton's method to the investigation of ammonia-salt solns. subjected to satn. with  $\text{CO}_2$ . Lab. expts. had shown that the ammonia-soda process in the course of carbonization is more involved than hitherto supposed, namely, in the initial stages of carbonization of  $\text{NH}_3$  or  $\text{NH}_3\text{-NaCl}$  soln. there is always formed the carbamino-acid ammonium salt, which on standing or on further satn. with  $\text{CO}_2$  reacts with  $\text{H}_2\text{O}$  and changes to carbonate, whether neutral or acid is not detd., and then in the form of  $\text{NH}_4\text{HCO}_3$  undergoes double decompn. with  $\text{NaCl}$ . Thus an equil. is always attained between the carbamate and the carbonate depending upon temp. This equil. between the carbamate, which does not go into a double decompn. with  $\text{NaCl}$  and the carbonate, which does undergo a double decompn. in presence of  $\text{CO}_2$ , explains why the process of sepn. of  $\text{NaHCO}_3$  during carbonization is never carried out to the end. These lab. investigations were extended at the "Chimugol" Donezkii Soda Works at Kharkoff, to the process of carbonization in towers of large-scale production with detn. of carbamates, carbonates and free ammonia throughout the entire length of the tower, and the results obtained fully confirm O.'s supposition. CHAS. BLANC

**The manufacture of caustic soda.** H. MORIN. *Russa* 4, 525-31 (1929).—A brief description of the manuf. of  $\text{NaOH}$  by chem. and electrolytic processes (electrolysis of  $\text{NaCl}$  solns., and of fused  $\text{NaCl}$ ), and of the concn. of  $\text{NaOH}$  solns. A. P.-C.

**Development of heat economy in the potash industry.** MAENICKE. *Arch. Warmewirt.* 10, 133-7 (1929).—Among the measures adopted for reducing the heat consumption in potash works are: the working of rich salts only; the substitution of mech. for steam agitation; the use of heat exchange by distg.  $\text{H}_2\text{O}$  under vacuum from the hot concd. liquors to the cold mother liquors; the preheating of the mother liquors with exhaust steam; the modernization of power plants. ERNEST W. THIELE

**Purification of brine by the sulfate method.** A. MITTENBERG. *Ukrainskii Khem. Zhur.* 2, Tech. Pt. 105-23 (1926).—A 3-stage method for elimination of  $\text{Ca}$  and  $\text{Mg}$  salts from the raw liquor used in prepn. of table salt is described. In stage 1 the raw liquor is mixed with mother liquor from previous cooks, soln. of  $\text{Na}_2\text{SO}_4$ , and milk of lime in such proportions that 100 cc. of clear filtrate requires for neutralization at least 10.5 cc. of 0.25  $N$   $\text{HCl}$ . In this stage  $\text{Mg}$  comes down as a hydrate, and the bicarbonates are changed to  $\text{CaCO}_3$ . The greater part of the  $\text{CaSO}_4$  also comes down, because of the high concn. of  $\text{Na}_2\text{SO}_4$ . The decanted liquid is then treated with scrubbed flue gases until 100 cc. of soln. titrates 0.5 cc. of acid and is allowed to stand until the ppt. comes down. Then  $\text{Na}_2\text{CO}_3$  is added until a test sample does not give any ppt. on addn. of  $\text{Na}_2\text{CO}_3$ . After 20 hrs. the clear liquor is used for evapn. The  $\text{Na}_2\text{SO}_4$  content is kept above 15 g. per l. for high concn. of alkali in stage 2, imperative for successful operation of the process. Calcs. and tables for computation of chemicals and the total cost under various conditions are given. With this method of purification not a trace of  $\text{CaSO}_4$  deposits on the evaporator tubes. REA MAIZEL

**The Trona enterprise.** G. ROSS ROBERTSON. *Ind. Eng. Chem.* 21, 520-4 (1929).—A review of the methods in use and the conditions surrounding the production of  $\text{K}_2\text{O}$  and borax at Searles Lake, Calif. W. H. ROSS

**The manufacture of carbon disulfide.** H. MORIN. *Russa* 4, 349-53 (1929).—A brief outline of the processes of manuf. of  $\text{CS}_2$  and of its properties. A. P.-C.

**Recovering sulfur from a Nevada surface deposit.** H. L. HAZEN. *Eng. Mining J.* 127, 830-1 (1929).—The coalescing method is employed with success. The ore is crushed to 10-mesh or finer, pulped with water, 1:1, sealed into a pipe 6 in. or less in diam. which is rotated and heated to  $138^\circ$ , and then cooled while rotating. With the

pipe diam. limited to 6 in. S collects and solidifies into a few lumps much larger than the screen openings, which permit all the gang to pass through. The large lumps contain 97% S, and the tailings about 3.5%. With ore testing 23% S, a recovery of 87% is indicated. The successive steps are: (1) the refiner is filled with filtered flotation concentrate contg. about 18% moisture; (2) the blow-off valve near the top of the refiner is closed and the Kelly head lowered into place and tightened; (3) steam is turned on at the bottom; (4) liquid S is drawn off through a specially constructed valve; (5) the blow-off valve at the top is opened and the pressure released; (6) Kelly head is released and the retort dumped and washed out. 2700 tons (2,454,300 kg.) have been produced by this method. Each cycle produces about 5 tons of pure S and about 7 cycles can be made in a 24-hr. day. Difficulties in refining the flotation concentrate are: failure of S to coalesce into a pool, and accumulation of gang around the S draw-off pipe. Tailings dumped from the refiner average about 35% S and are returned to the flotation circuit. "Aerofloat No. 15," in the proportion of 0.25 g. per kg. of ore, gave the best results. Recovery averaged 85%. The concentrate averaged 77% S and the mill heads (half mine and half dump ore) about 15% S. W. H. BOYNTON

Volumetric relations of the reaction  $N_2 + O_2 \rightleftharpoons 2NO$  — 43,200 gram calories. R. NITZSCHMANN. *Metallbörse* 18, 1799-1800(1928).—A mathematical discussion and tabulation of the results. E. M. SYMMES

Silicic acid gel and silica gel. KUNO WOLF AND MAX PRAETORIUS. *Metallbörse* 19, 341 2(1929); cf. *C. A.* 23, 2787.—A review. W. C. EBAUGH

Metallurgical limestone—problems in production and utilization. OLIVER BOWLES. *Bur. Mines, Bull.* No. 299, 40 pp.(1929); cf. *C. A.* 22, 1124.—A rept. purporting to cover present knowledge of the utilization of metallurgical stone and the problems connected with its quarrying or mining and prepn. There is a marked tendency toward underground mining of limestone which tends to produce a stone of higher purity. Utilization problems are approached from the standpoints of: blast-furnace flux, basic open-hearth flux, and limestone flux in non-ferrous metallurgy. Production problems of fluxing limestone are discussed from the standpoints: the relation of metallurgical stone production to other limestone industries; prospecting; plan of development; impurities, quarrying to maintain uniformity in rock compn.; by-product industries; and production cost of fluxing stone. W. H. BOYNTON

Factors affecting the solution rates of limestone in acid media. HERBERT F. KRIEGER. *Rock Products* 32, No. 10, 73-80(1929).—The soln. rate of limestone in dil. buffer d acid solns. is inversely proportional to particle size. The rate for any limestone is specific for that stone. Phys. properties are not an indication of soln. rate. Compn. affects the rate to a marked degree,  $MgCO_3$  dissolving more slowly than  $CaCO_3$ . RAYMOND WILSON

Efficiency and fuel consumption of gas-fired lime kilns. A. SCHACK. *Arch. Warmwirts.* 7, 65-9(1926); cf. *C. A.* 21, 990.—An analysis of the heat balance and equal conditions on a lime kiln, with reasonable assumptions as to radiation loss, shows that the heat liberated by the gas is equal to the heat required to raise the flue gases, exclusive of  $CO_2$  from the limestone, to a temp.  $t$ , less the heat given off in cooling the lime below the temp.  $t$ , plus 840 cal. per g. of  $CaO$  produced. The temp.  $t$  is that at which  $CaCO_3$  has a  $CO_2$  pressure equal to the  $CO_2$  partial pressure in the stack gases. The efficiency of a kiln increases as the flame temp. of the fuel rises; 70% is a max. unless the heat in the stack gases is recovered. ERNEST W. THIELE

Development of modern kiln design. E. L. JOHNSON. *Cement, Mill and Quarry* 34, No. 5, 45-7(1929).—Lime kilns are discussed. E. I. S.

Graphite. I. General information. PAUL M. TYLER. *Bur. Mines, Circ.* No. 6118, 45 pp (1929); cf. following abstr.—A very complete rept. on the history, uses, properties, mining, concn. and refining methods for graphite. The manuf. of artificial graphite, the world and domestic production of graphite, grades, prices, etc., are discussed, and an excellent bibliography is appended. W. H. BOYNTON

Graphite. II. Domestic and foreign deposits. PAUL M. TYLER. *Bur. Mines, Circ.* No. 6122, 25 pp.(1929). III. Utilization of graphite. *Ibid* 6123, 20 pp. IV. Status of the American graphite industry. *Ibid* 6124, 14 pp. Cf. preceding abstr. E. H.

Proposed method for testing casein. ELBERT G. MILHAM. *Paper Trade J.* 88, 55-6(1929).—A description of the proposed official method of the Technical Assocn. of the Pulp and Paper Industry. A. PAPINEAU-COUTURE

Analytical differences between acid casein and rennet casein. CH. PORCHER AND MISS J. BRIGANDO. *Ann. fals.* 22, 153-63(1929); cf. *C. A.* 22, 3672; Fouassier, *C. A.* 22, 4733 —There is no essential difference between "acid" casein and "lactic" casein.

By observing proper precautions in manuf., either process can give a product practically as pure as that obtained in the lab.; the analytical differences in the various com products are due to carelessness or improper processing. The constitution and compn of rennet-casein are different, as shown in the previous paper. Certain of Fouassier's statements are challenged.

A. PAPINEAU-COUTURE

Filtering equipment and the systematic and continuous extraction of sludges, precipitates and ores (FOURTON) 1. Some properties of fuller's earth and acid-treated earths as oil-refining adsorbents (DAVIS, MESSER) 22. Government potash exploration in Texas and New Mexico (MANSFIELD, LANG) 8.

**Phosphoric acid.** EDOUARD D. MATHEY and AUDLEY O. WILLIAMS. (to American Cyanamid Co.). U. S. 1,714,685, May 28. An inorg. material capable of liberating P, such as a mixt. of phosphate rock,  $\text{SiO}_2$  and coke, is heated with sticks of carbonized wood in an elec. furnace.

**Sulfuric acid.** VEREIN FÜR CHEMISCHE UND METALLURGISCHE PRODUKTION Fr. 652,440, Apr. 10, 1928. See Brit. 289,879 (C. A. 23, 936).

**Concentrating acids.** HOLZVERKOHLLUNGS-INDUSTRIE A.-G. Fr. 651,944, Mar. 29, 1928. Aliphatic acids, particularly  $\text{AcOH}$ , are concd. by distg. in the presence of  $\text{NaHSO}_4$ ,  $\text{H}_2\text{SO}_4$ , or mixts. thereof and by bringing the vapors into contact with fused  $\text{NaHSO}_4$ .

**Ammonia.** KALI-INDUSTRIE A.-G. and THEODOR C. THORSSELL. Fr. 652,174, Mar. 20, 1928. See Brit. 288,154 (C. A. 23, 486).

**Ammonia.** NITROGEN ENGINEERING CORP. Fr. 651,899, Mar. 28, 1928. In the synthetic production of  $\text{NH}_3$  a small quantity of  $\text{CO}_2$  is introduced into the circulating H and N to form  $(\text{NH}_4)_2\text{CO}_3$  with the water vapor present and  $\text{NH}_3$ . Other impurities such as dust and oil are removed with the  $(\text{NH}_4)_2\text{CO}_3$ . Cf. C. A. 23, 3313.

**Alkali metal silicates.** I. G. FARBENIND. A.-G. Brit. 299,763, Oct. 31, 1927. Raw siliceous materials such as finely ground sand are heated under pressure with liquor. contg. alkali metal chloride and hydroxide obtained by electrolysis of  $\text{NaCl}$  or  $\text{KCl}$  solns.

**Inositolhexaphosphates.** FRITZ GOEDECKE. U. S. 1,715,031, May 28. Comminuted parts of plants contg. inositol hexaphosphoric acid are extd. with water, the acid and acid salts in the aq. soln. are converted into neutral alk. earth metal salts as by addn. of  $\text{CaCO}_3$  and these salts, which are practically insol. in water, are sepd. by filtration and are treated with oxalic acid to liberate the acid and acid salts from the pptd. compds.

**Fluorine compounds.** VEREIN FÜR CHEMISCHE UND METALLURGISCHE PRODUKTION Fr. 652,258, Apr. 5, 1928. The gases obtained by the action of  $\text{H}_2\text{SO}_4$  on F compds. such as fluorspar are dehydrated with oleum, and the  $\text{HF}$  is condensed. The residual gases rich in volatile compds. of Si are absorbed in water and used for making  $\text{AlF}_3$  or double fluorides of Al and alkali metal. The diluted oleum is used for reacting with more fluorspar.

**Molding zirconium and other oxides.** DEUTSCHE GASGLÜHLICHT-AUER-G. M B H Fr. 652,256, Apr. 5, 1928.  $\text{ZrO}_2$ ,  $\text{ThO}_2$  and  $\text{BeO}_2$  are made plastic or capable of being cast for making objects therefrom, by mixing with water and less than 5% of  $\text{MgO}$  or  $\text{Al}_2\text{O}_3$  or mixts. thereof and a small quantity of a salt soln. of the oxide to be made plastic or of the oxide to be added.

**Alumina, etc.** I. G. FARBENIND. A.-G. Brit. 300,184, Aug. 4, 1927. Materials such as clay, phonolite or leucite are treated with  $\text{H}_2\text{SO}_4$  or a mixt. of  $\text{H}_2\text{SO}_4$  and  $\text{HCl}$ , the soln. is sepd. from the residue and is evapd. with a quantity of  $\text{NaCl}$  equiv. to the  $\text{H}_2\text{SO}_4$  and the residue is heated to  $700^\circ$ ;  $\text{HCl}$  is evolved and the sintered product is further heated to  $1000^\circ$  with C to produce Na sulfide, Na aluminate and soda; the product is lixiviated, some Na sulfide may be sepd. by crystn. and alumina is pptd. by use of  $\text{H}_2\text{S}$  or  $\text{CO}_2$  or a mixt. of these gases. Addnl. Na sulfide may be then crystd. and the mother liquor may be treated with  $\text{CO}_2$  to sep.  $\text{NaHCO}_3$ . Various other details and modifications of the process are described.

**Aluminum chloride.** HENRY I. LEA and CLIFFORD W. HUMPHREY. U. S. 1,713,968, May 21. Hot Al oxide is treated in a retort with hydrocarbon vapors in sufficient quantity to impregnate the oxide with hydrocarbons carrying an excess of C over that required for chlorination; the material thus treated is then treated with  $\text{Cl}_2$ . An app. is described.

**Ammonium phosphate.** I. G. FARBENIND. A.-G. Brit. 299,796, June 29, 1927. Mono- and di-Ca phosphates are treated in the presence of water with  $\text{NH}_3$  or  $(\text{NH}_4)_2\text{CO}_3$  to produce a soln. of  $\text{NH}_4$  phosphate and a residue of difficultly sol. tri-Ca phos-

plate which is treated with acid to form further quantities of mono- and di-Ca phosphate. Pressure and heating may be employed.

**Ammonium sulfate.** S. ROBSON. Brit. 299,934, Aug. 16, 1927. Crude ammoniacal liquor such as that from gas works is distd. to free it from non-volatile N compds., the distillate is concd., if required, to an  $\text{NH}_3$  content of over 6%, and is then volatilized at such a temp. that the proportions of  $\text{NH}_3$  gas and  $\text{H}_2\text{O}$  vapor in the resulting gaseous mixt. are correct for combination with  $\text{SO}_3$  to produce dry neutral  $(\text{NH}_4)_2\text{SO}_4$ . The latter may be recovered by bag filters or by electrostatic sepn. Cf. C. A. 23, 938.

**Barium sulfate.** SERGE WITTOUCK. Fr. 652,675, Apr. 13, 1928.  $\text{BaSO}_4$  is formed by the decompn. of an alkali sulfate with  $\text{Ba}(\text{OH})_2$ .

**Calcium hypochlorite.** JESSE A. GUYER (to Mathieson Alkali Works). U. S. 1,713,654, May 21. Ca hypochlorite products contg.  $\text{CaCl}_2$  are freed from the latter by the action of caustic alkali in the presence of water.

**Calcium hypochlorite.** ANTHONY GEORGE and ROBERT B. MACMULLIN (to Mathieson Alkali Works). U. S. 1,713,650, May 21. See Ger. 473,924 (C. A. 23, 3058).

**Calcium hypochlorite.** ROBERT B. MACMULLIN and ANTHONY GEORGE (to Mathieson Alkali Works). U. S. 1,713,668, May 21. See Ger. 474,080 (C. A. 23, 3058). U. S. 1,713,669 specifies chlorinating milk of lime, adding caustic alkali to the chlorinated milk of lime slurry, continuing the chlorination, and sepg. the Ca hypochlorite produced.

**Potassium nitrate.** KALI-INDUSTRIE A.-G., THEODOR THORSSSELL and AUGUST KRISTENSSON. Fr. 651,685, Feb. 2, 1928. See Brit. 287,133 (C. A. 23, 488).

**Drying sodium silicate.** AKTIEBOLAGET MALMO GLASBRUK (to Aktiebolaget Termolit). Brit. 300,141, Nov. 5, 1927. In order to obtain "waterglass" in the form of hollow globes or balls for use as an *insulating material*, it is preliminarily dried to a solid mass and reduced to grains as by milling; the grains are subjected to heating on a surface such as that of a metal plate heated to dull redness over which they are moved. Alternatively, the fluid waterglass may be passed through a sieve, the drops dried by a current of hot air and the grains thus formed then further heated on a hot surface.

**Purifying caustic soda.** D. A. PRITCHARD and UNITED ALKALI CO., LTD. Brit. 299,995, Oct. 21, 1927. Dil. caustic liquor such as the effluent from electrolytic cells may be purified from  $\text{NaCl}$  by evapn. and subsequent addn. of  $\text{Na}_2\text{SO}_4$  (or other suitable salt of  $\text{H}_2\text{SO}_4$ ) or of  $\text{H}_2\text{SO}_4$  itself. Various details are given.

**Metal carbonyls.** I. G. FARBENIND. A.-G. Fr. 652,594, Apr. 12, 1928. Metal carbonyls are prepd. by oxidizing the metal and reducing one or more times and then treating with  $\text{CO}$ . Examples are given of the prepn. of the carbonyls of Ni and Fe. Cf. C. A. 23, 938.

**Sulfur-burning apparatus.** OTTO BUSE (to Grasselli Chemical Co.). U. S. 1,714,657, May 28. Melted S is delivered onto an inclined corrugated plate in a gas conduit. Cf. C. A. 23, 2539.

**Apparatus for a continuous discharge of burned lime from the kiln.** A. L. PYATAKOV. Russ. 5621, June 30, 1928. Mechanical features are specified.

**Gels.** THE SILICA GEL CORP. Fr. 652,269, Apr. 5, 1928. See Brit. 289,890 (C. A. 23, 941). Fr. 652,270 describes the prepn. of gels of  $\text{SiO}_2$ , oxides of Al, Ti, W, etc., in which the hydrogel is washed with water at 21–80°, preferably 65°, whereby after drying a gel is obtained, the apparent d. of which is less affected when strongly heated. Cf. C. A. 23, 3315.

**Silica gel.** THE SILICA GEL CORP. Fr. 652,022, Mar. 31, 1928. Solns. of a sol. silicate and an acid in such concn. and amt. that the mixt. solidifies are stirred together and the hydrogel formed on allowing to stand is washed with hot water, treated with an acid, preferably  $\text{H}_2\text{SO}_4$ , increasing in concn. from 45° Bé. to 60° Bé. and decreasing again to 45°, and washed again with hot water. The gel has an apparent d. not over 0.70 after activation at 870°.

**Decolorizing substances.** LA CARBONISATION (SOC. GÉNÉRALE D'EXPLOITATION DE CARBONES). Fr. 652,156, Sept. 16, 1927. Charcoal from wood, peat, lignite, etc., is reduced to a fine powder, freed from tars by treatment with  $\text{NaOH}$  or  $\text{KOH}$  solns., then with dil. acids and washing, and mixed with Ca phosphate (80%) and with or without  $\text{Al}_2\text{O}_3$  (5%). The mixt. is heated to 600–900°, giving a valuable decolorizing compd.

**Separating asbestos fiber from rock, etc.** THOMAS ROSE (to Selective Treatment Co., Ltd. and Powhatan Mining Corp.). U. S. 1,714,438, May 21. The mineral is submerged in water and passed repeatedly through a rubbing and crushing app. by continuous recirculation of the water, and sepn. is effected by flotation and sedimentation. An app. is described. Cf. C. A. 22, 4209.

**Molded carbonaceous articles such as electrodes.** HARVEY N. GILBERT (to Roess-

ler & Hasslach Chemical Co.). U. S. 1,714,165, May 21. A shaped article of an apparent sp. gr. over 1.7 is made by filling a mold with a mixt. of comminuted graphitized C and a carbonaceous plastic binder such as pitch, compressing the mixt. and carbonizing the binder while resisting by mech. means expansion of the formed body, and then further heating (suitably at a temp. of about 1000°) to give addnl. d.

**Composition for sound records or other molded articles.** WILLIAM McC CAMERON (to Celanese Corp. of America). U. S. 1,713,740, May 21. Acetanilide 5-50 and rosin 95-50 parts are used together in a compn. which may also contain fillers, coloring substances, etc.

**Sound records.** BRITISH THOMSON-HOUSTON CO., LTD., H. N. SPORBORG, A. P. YOUNG and A. T. WARD. Brit. 299,752, July 27, 1927. A thin metal disk (which may be perforated) or metal gauze is coated on one or both sides with a synthetic resin (preferably one formed from phthalic anhydride and glycerol) and an addnl. thin coating of shellac is applied for receiving the sound-groove impressions. The resin may be mixed with a filler such as wood flour or chalk and coloring substances.

**Curing and dyeing foliage.** DAVID S. ANDERSON. U. S. 1,714,838, May 28. Foliage such as ferns for decorative work is impregnated with a curing and color-changing soln. contg.  $\text{CaCl}_2$ , HOAc, glycerol and alc., and is afterward immersed in a soln. contg. these same ingredients together with an aniline dye and camphor and gum arabic, and is finally immersed in a soln. contg. water, gum arabic and aniline dye and some of the curing and color-changing soln.

**Emulsions for use as detergents, in dyeing, etc.** F. W. ATTACK. Brit. 299,817, April 19, 1927. A liquid emulsion readily miscible with water is prepd. by emulsifying a grease solvent such as trichloroethylene or other chlorinated hydrocarbon, in water by use of Turkey red oil and stabilizing the emulsion with bentonite or similar natural colloidal hydrosilicate. Small proportions of fatty acids and  $\text{NH}_3$  may be added. Emulsions thus formed may be used as detergents for cleaning or washing clothes, in scouring, dyeing, finishing wool, cotton, artificial silk or mercerized cotton, degumming silk, as wetting agents in dyeing, removing ink from paper stock and for application to the Foudrinier wires or to the sulfite digester or wood grinder in the paper making industry.

**Wax-like products from halogenated saturated hydrocarbons.** J. BAER. Brit. 300,200, Nov. 8, 1927. Halogen compds. such as methylene and ethylene dichlorides or dibromides are treated with a "thinned"  $\text{NH}_4$  sulfide soln. which is stated to produce a wax-like material harder than beeswax or carnauba wax.

**Metallizing various surfaces.** A. I. GATES-WARREN, E. L. GATES-WARREN and PRECIOUS METAL INDUSTRIES, LTD. Brit. 299,903, Aug. 2, 1927. Non-cond. materials such as casein products, cellulose acetate, vegetable and synthetic gums, tortoise-shell, urea and phenol condensation products, etc., which have or may be given a porous surface by abrasion, if necessary, are treated with a suspension or paste of a metal salt and metal and exposed to light or to the action of a reducing agent such as  $\text{CH}_2\text{O}$  or furfural. The article may be subsequently electroplated if a heavier metal coating is desired.

**Composition for sealing intermeshed joints of metal barrels or drums, etc.** RICHARD L. PARISH (to American Flange & Mfg. Co.). U. S. 1,713,675, May 21. A sealing mixt. suitable for use when dild. with an equal quantity of benzene is formed of Ceylon crepe rubber 46.6, pptd.  $\text{CaCO}_3$  46.6,  $\text{ZnO}$  4.7, S 1.8 and tetramethylthiuram disulfide 0.3%.

**Treating rubber gaskets with hot paraffin.** HARRY C. LOUDENBECK (to Westinghouse Air Brake Co.). U. S. 1,714,033, May 21. Rubber gaskets such as those which are to be used between metal surfaces are dipped in a bath of paraffin which is heated to a temp. of about 90-120°.

**Reclaiming dry mats for preparing matrices for newspaper or like printing.** GORDON W. NELSON. U. S. 1,713,913, May 21. A previously used and pre-moistened matrix is rolled into a flat sheet and its reverse side is prepd. for and given another impression.

**Waterproof sheet material suitable for automobile tops, etc.** CHARLES H. RAYNER. U. S. 1,714,240, May 21. Loose hair is spread on a reinforced paper sheet backing or binding sheet, the material is punched through with barbed points carrying loops and ends of hair strands through it, the loops and ends projecting through the sheet are singed, the singed hair and back are covered with asphalt and an artificial leather compn. is applied over the asphalt.

**Composition for waterproofing paper conduits or tubing, etc.** WALLACE B. VAN ARSDEN (to Brown Co.). U. S. 1,714,702, May 28. See Can. 284,377 (C. A. 23, 681).

**Removal of water from "carbolite."** G. S. PETROV. Russ. 5588, June 30, 1928. To remove the water the goods are heated in a medium of org. solvents with the addn. to the latter of paraffin, wax, ethers, cellulose or tars.

**Paint and varnish remover.** ADDIE TREMAIN and HARRY D. TREMAIN. U. S. 1,714,530, May 28. NaOH 25 lbs., "hydrated calcium" 40 lbs., fuller's earth 5 lbs., Na<sub>2</sub>PO<sub>4</sub> 5 lbs., red Mn oxide 10 lbs., powdered starch 5 lbs. and methyl salicylate 1 dram.

**Removing non-vitreous enamel from metals.** HARRY O. LANG. U. S. 1,714,879, May 28. The enameled article is immersed in a molten bath comprising mainly an alkali metal nitrate or nitrite or both.

**Plastic caps for milk bottles, etc.** LAKEWEST CORP. Brit. 300,001, Oct. 26, 1927. Several laminations of fibrous material such as crinkled paper are partially impregnated and fully consolidated with earthy and resinous substances such as a mixt. of terra alba and deodorized rosin. It is stated that the rosin may be deodorized by melting and treating with a small proportion of "sodium bisulfide."

**Testing the strength of acid and alkali solutions of fire extinguishers.** GEORGE B. TOURTELLOTTÉ. U. S. 1,714,197, May 21. A measured sample of each soln. is placed in a container having normally sepd. compartments which are open at their upper ends; the app. is provided with a closure and pressure gage and is inverted to mix the solns. so that the pressure developed by gas generation from their reaction may be noted. The app. is described.

## 19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

**The Carl Zeiss Works and the Zeiss Foundation.** ANON. *Engineering* 127, 665-8 (1929). E. H.

**The theoretical basis of chemical attack on glass from the consideration of its action against water.** P. TIETZE. *Sprechsaal* 61, 809-10(1928).—The chem. attack on glass is treated as a heterogeneous solid-liquid system. The soln. velocity depends on the surface of contact and on the concn. of the dissolved material in the solvent.

C. H. LORIG

**The relation of heat conductivity of glass to the chemical composition.** ALFRED RUSS. *Sprechsaal* 61, 887-91(1928).—The temp. coeff. and heat cond. of a variety of glasses were detd. for the temp. interval 0-100°. Glass plates 3 × 3 sq. cm. and 0.1 to 0.2 cm. thick were securely held between Cu plates and the heating element of the app. Temp. drops between plates were detd. with thermocouples embedded in the Cu. The glass-forming oxides, SiO<sub>2</sub>, B<sub>2</sub>O<sub>3</sub>, MgO, Al<sub>2</sub>O<sub>3</sub>, Fe<sub>2</sub>O<sub>3</sub>, ZnO, Na<sub>2</sub>O, PbO, BaO and K<sub>2</sub>O, influence the heat concn., the first-mentioned oxides exerting the greatest influence. Heat concn. values calcd. from the glass components are in agreement with measured values. The av. error is ± 1.66%. Heat concn. is an additive or an approx. additive property of glass.

C. H. LORIG

**Thermal movements in glass.** E. BERGER. *Sprechsaal* 61, 827-31(1928).—Movements in a glass batch occur when various parts are at different temps. The hottest columns of glass flow in a direction opposing the force of gravity.

C. H. LORIG

**Determination of solution alkalinity of granulated glass.** ERNST FISHER AND WALTER TEPOHL. *Sprechsaal* 61, 847-8(1928).—The solubilities of 5 glasses in distd. water held for 3 hrs. at 80° were detd.

C. H. LORIG

**Calculation of glass constants on the basis of recent investigations.** E. ZSCHIMMER. *J. Soc. Glass Tech.* 12, 82-118T(1928).—The recent literature is reviewed in the effort to combine sufficient data of the phys. properties of glasses to permit the calcn. of const. for a glass of given compn. The phases considered are the method of permutants, covering the specific effects of the oxides, the devitrification const. of soda-lime-silica glasses, their working viscosities at high temps. and the effect of CaO, MgO, Al<sub>2</sub>O<sub>3</sub>, B<sub>2</sub>O<sub>3</sub>, etc., on the viscosities. *Ibid* 333-66T.—The recent investigations on the density-thermal expansion,  $n$ , elec. cond. and the annealing properties of glass show that our present information is too incomplete to calc. glass const. from known compn.

H. F. KRIEGE

**The significance of Brenker phonolite in the glass industry.** HUGO KÜHL. *Schnurpfel's Rev. for Glass Works* 13, 3321-5(1929).—A study of German minerals for use in the glass industry showed Brenker phonolite to be one of the best natural stones. Its value lies in its high alkali content, which reaches 18%. A typical analysis shows

alumina 24, iron oxide 2.3, silica 50.3 and alkali 17.6%. It has been found very suitable for colored glasses, but because of the Fe content its use is limited in the production of colorless glass. Batches from various sources are given using as high as equal parts of sand and phonolite for brown bottles. One part of phonolite to 10 parts of sand may be used for light green medicine bottles.

M. A. EDDY

**Characteristics of refractory clays for the glass industry.** G. GEHLHOFF, H. KAL-SING, K. LITZOW AND M. THOMAS. *J. Soc. Glass Tech.* 12, 213-79, 280T(1928).—Twenty clays used in the German and Bohemian glass industries were examd. chemically, physically and microscopically to relate their properties with their behavior as refractories. It was found that the chem. resistance and the stability of clays at high temps. increase generally with their  $Al_2O_3$  content, their firing temp. and the density to which they are burned. Porosity is the chief factor detg. the resistance of refractories to corrosion by raw batch materials and molten glass. The high sintering temps. of clays rich in  $Al_2O_3$  gives them porosity under ordinary burning conditions, which overcomes their resistant qualities due to chem. compn. When grains of grog are under 2 mm. diam., their size has no influence on the softening temp. under load. The grain size does affect the resistance to chem. action, particularly with clays low in  $Al_2O_3$ . The density of the refractories is more important than their chem. compn. when corrosion by glass in motion is considered. The presence of accessory minerals, such as  $Fe_2O_3$  and feldspar, affects the refractoriness of clays regardless of their chem. compn. otherwise. Small quantities of feldspar may serve advantageously in lowering the sintering temp. and thus decreasing the porosity of a glass refractory.

H. F. K.

**The manufacture of sheet and window glass.** H. SCHNURPFEL. *Schnurpfel's Rev. for Glass Works* 13, 3243-5(1929).—There are two standard window glass batches, one contg. soda ash as a flux and the other contg.  $Na_2SO_4$ . The addn. of  $KNO_3$ , arsenic and manganese to the soda ash batch makes the glass suitable for photographic dry plates. For drawn window glass a softer glass contg. barytes is desirable. The soda ash batch may be used as a basis for colored sheet glass and batches are given using the following coloring agents: violet glass using manganese and saltpeter, brown-violet using manganese and iron oxide; carbon yellow using powdered charcoal and  $Na_2SO_4$ ; yellow using ferruginous manganese; black using manganese and cobalt oxide; green using copper oxide, iron oxide and  $K_2Cr_2O_7$ ; milk-white using red lead, cryolite, feldspar, flourspar, bone ash and arsenic; aquamarine using copper oxide, blue using cobalt oxide. All these batches have been used successfully.

M. A. EDDY

**Lead glass and its use.** C. A. BECKER. *Metallwirtschaft* 7, 230-1(1928).—Summarizing review on the compn. and the technology of Pb glasses. Among the more important applications are table glassware, the optical glasses, imitations of precious and semi-precious stones and protective material for x-ray work (some Pb glasses show the same absorption of x-rays in a 20 mm. layer as solid Pb of 5 mm. thickness).

EMIL KLARMANN

**Ultra-violet light-transmitting glasses.** DAVID STARKIE AND W. E. S. TURNER. *J. Soc. Glass Tech.* 12, 306-21(1928); cf. *C. A.* 22, 2821.—Com. glasses transmitting rays between 2950 A. U. and 3150 A. U. were considered. A photometer of the "platinum wedge" type was employed to measure the transmitting properties of the several glasses. Corex glass contg. the least Fe (0.012%  $Fe_2O_3$ ) showed the highest transmission, namely, 89% as compared with 1% of ordinary window glass. The transparency to ultra-violet rays decreased in some glasses with prolonged exposure to sunlight. With exposure to a C arc light all the glasses lost in transmitting power. The change appeared due to the oxidation of the  $Fe^{++}$  present.

H. F. KRIEGER

**Influence of ferric oxide content on the light transmission of soda-lime-silica glass, with special reference to the ultra-violet.** D. STARKIE AND W. E. S. TURNER. *J. Soc. Glass Tech.* 12, 324-32(1928).—To glasses contg.  $SiO_2$  75,  $CaO$  19 and  $Na_2O$  15%,  $Fe_2O_3$  was added in amounts between 0.005 and 1.0%. The melts were made in Pt after they had been sintered for 6 hrs. in  $SiO_2$  crucibles to decrease the soln. of the Pt. When the  $Fe_2O_3$  content of the glasses was plotted against the wave-length limit in the ultra-violet region, a smooth curve was obtained. An  $Fe_2O_3$ -free glass of this compn. should have a transmission limit of 2300 A. U. Four glasses contg. up to 1.01%  $Fe_2O_3$  on exposure to light from a C arc showed no change in transmission power since practically no FeO was present.

H. F. KRIEGER

**The action of glass towards sodium hydroxide at high temperatures.** FRITZ FRIEDRICHS. *Sprechsaal* 61, 967-9, 980-6(1928).—The loss of wt. and alkali loss or gain in 1N NaOH soln. was detd. for 14 glasses of different compns. in the temp. range of 100° to 300°. The alkali loss in 1N NaOH decreases with increased  $B_2O_3$  content. Porcelain shows no alkali loss; instead, even at low temps., it takes alkali from the soln.

On investigating the influence of time on the action of 1N NaOH toward 3 characteristic glasses, it was found that at temps. above 170° the loss of wt. becomes independent of the time of action. An equil. results between the glass and soln. This equil. is not obtained at temps. below 170°. The effect of NaOH concn. from 5N to infinite diln. was obtained for 3 glasses. For strongly acid glasses the loss of wt. for a definite time as well as for a definite concn. of NaOH becomes const. C. H. LORIG

The manufacture of glass for electric incandescent lamps. JOSEPH TISCHER. *Sprechsaal* 61, 788-90(1928). C. H. LORIG

The glass-melting furnace as a heat machine. D. AUFHÄUSER. *J. Soc. Glass Tech.* 12, 297-306(1928). H. F. KRIEGER

Theory and practice of cooling glassware. E. ZSCHIMMER. *Sprechsaal* 61, 869-72 (1928).—The distribution and magnitude of compression and tension forces in the interior of glass are most easily detd. through observations in a polarization app. The cooling process consists of 2 operations, the tempering of the glass and the uniform cooling of the tempered glass. It is essential to know the tempering temp. and the time-temp. relation for cooling glassware. C. H. LORIG

Temperature distribution in the Fourcault machine during the cooling process. K. L. SCHARASCHKIN AND W. E. BROMLEY. *Sprechsaal* 61, 790-1(1928). C. H. L.

Strength of brick. ALFRED B. SEARLE. *Brick and Clay Record* 74, 402-3(1929).—Some fire brick are stronger when being fired than when cold. Silica brick are weaker at 200° than at any other temp. below 800°. The strength increases to that of cold silica brick between 300° and 575° but then falls rapidly as the temp. increases; the cause is unknown. H. G. SCHURECHT

Investigation of twenty-one Saskatchewan ball clays. W. G. WORCESTER. *J. Am. Ceram. Soc.* 12, 360-76(1929).—The clays have com. value. Raw strength is unusually high. C. H. KERR

A new method of treating clays to overcome drying defects. J. G. PHILLIPS. *Can. Mining Met. Bull.* No. 203, 470-81(1929).—The use of 2 clays, abundant in the Prairie Provinces of Canada, has been handicapped by cracking in drying. These drying defects can be overcome by: (1) preheating to from 450° to 550°, or (2) using grog plus chem. coagulants; FeCl<sub>3</sub> and a mixt. of FeCl<sub>3</sub> and NaCl were efficient. The best mixt. for method (2) was 85% clay (2 parts soft clay to 1 shale), 15% grog (ground brick bats), plus 1% FeCl<sub>3</sub> and 0.5% NaCl, added in the pug water. This reduced the drying loss from 40% to almost nothing, reduced the time from 7 or 8 to 3 days and improved the color and general properties. A. BUTTS

Plasticity and water absorption of clays. H. B. OAKLEY. *Nature* 123, 714-5 (1929).—Expts. on absorption of 0.1 N NaCl soln. show that the plasticity range with respect to water content increases with ability to absorb NaCl soln. The absorption increases with diln. of the soln. Tables show the influence of the base used. G. M. E.

Properties of the clay-water system. OTTO BARTSCH. *Ber. deut. keram. Ges.* 10, 146-83(1929).—A method of detg. the resistance of clay slips to deformation is described. The results are similar to those obtained with viscosity measurements. H. G. SCHURECHT

Accomplishments of Structural Clay Tile Association. EDWARD C. KERTH. *Brick and Clay Record* 74, 394-6(1929). H. G. SCHURECHT

The prediction of service value (of ceramic materials) from laboratory test data. A. E. R. WESTMAN. *J. Am. Ceram. Soc.* 12, 319-29(1929). C. H. KERR

Flotation as a means of purifying kaolin. H. KLAR. *Keramos* 8, 7-11(1929).—The flotation process for purifying ores has been used with success. A special flotation process known as the "Schaum-Schwimmverfahren" is suggested as a means of purifying primary kaolins. H. G. SCHURECHT

Kaolin deposits suitable for pottery manufacture. A. K. DENMEAD. *Queensland Govt. Mining J.* 30, 99-101(1929).—Of the known clay deposits only a small number can be classed as pottery clays. Seventeen localities are enumerated and a brief description is given of the deposits, with analysis in some cases. E. I. S.

Rate of drying of a plastic porcelain mass due to reduced pressure and heat. LOUIS NAVIAS. *J. Am. Ceram. Soc.* 12, 305-18(1929).—Reduced pressures of 0.7, 5, 15 and 35 cm., with temps. of 23, 50 and 65° were tried. Straight line relationships for rate of drying were found when the log of loss of wt. was plotted against log of time. With the lowest pressure a single slope was found, but with the higher pressures there were 2 slopes to each curve. C. H. KERR

A sandblast abrasion test for glazes. EDWARD SCHRAMM. *J. Am. Ceram. Soc.* 12, 356-9(1929).—The app. is described. C. H. KERR

A new type of tunnel kiln for firing pottery. J. WILLIAMSON. *Trans. Ceram. Soc. (England)* 27, 290-6(1928); cf. *C. A.* 22, 2251. H. F. KRIEGER

The new tunnel kiln of the Steatit-Magnesia Joint-Stock Co. M. THURNAUER. *Keramos* 8, 4-9(1929).—It is 63 m. long, holds 36 cars and the firing time is 54 hrs. H. G. SCHURECHT

Studies on firing ceramic round furnaces. O. TIPPMMANN. *Sprechsaal* 61, 707-9, 725-7(1928).—Curves are given to show the effect of CO<sub>2</sub> on the temp. of the hot gases and the time required to heat the muffle to a known temp. C. H. LORIG

A faience oven of the Winterthur master, Hans Heinrich Graf 1688, in the museum of Ulm. MAX SCHEFOLD. *Sprechsaal* 61, 1022-4(1928). C. H. LORIG

Use of pulverized coal as a fuel for periodic kilns. D. J. WATSON. *J. Am. Ceram. Soc.* 12, 336-41(1929). C. H. KERR

A new refractory material (Wetamaterial). A. KARSTEN-SALMONY. *Korrosion* 4, 17(1929).—"Weta" is suitable as a porcelain and quartz glass substitute for lab. app. It is made of powd. SiC mixed with silicates and certain metals. It resists acids, alkalis, temp. shock and is not easily broken. J. H. MOORE

Refractories and boiler furnace linings. REGINALD TRAUTSCHOID. *Paper Trade J.* 88, No. 17, 56-60(1929). A. PAPINEAU-COUTURE

Comparative tests on monolithic refractory cements. H. N. CLARK. *J. Am. Ceram. Soc.* 12, 330-5(1929). C. H. KERR

Study on enameling agent. T. UCHIDA. *Repts. Imp. Ind. Research Inst., Osaka, Japan* 9, No. 4, 1-381(1928).—By combining various proportions of Na<sub>2</sub>CO<sub>3</sub>, K<sub>2</sub>CO<sub>3</sub>, orthoclase, H<sub>3</sub>BO<sub>3</sub>, Zn white, CaCO<sub>3</sub>, fluorspar, MgO, Al<sub>2</sub>O<sub>3</sub>, quartz, clay, feldspar, Na<sub>2</sub>SiF<sub>6</sub>, Co<sub>2</sub>O<sub>3</sub> and saltpeter, about 2000 specimens of frit were prepd. and studied when applied on Cu, cast Fe, or steel plates. Examn. was made of luster, emulsification, shrinkage, amt. of bubbles and cracks and the degree of adhesion. The influence of compn. on quality is discussed. The relation is complicated and no hard and fast rule can be given. The standard compn. of an enameling agent can be expressed by 1.5 R<sub>2</sub>O, 1 RO, 0.5 B<sub>2</sub>O<sub>3</sub>, 3 SiO<sub>2</sub> (where R = a metallic element). About 250 pp. of tables and numerous photomicrographs are presented. NAO UYEI

Enameling agent containing antimony. T. UCHIDA AND K. ARIKI. *Repts. Imp. Ind. Research Inst., Osaka Japan* 9, No. 1, 1-33(1928).—Various combinations of enameling agent, contg. various amts. of (a) Sb<sub>2</sub>O<sub>3</sub> + KNO<sub>3</sub> (2:3), (b) fluorspar, (c) cryolite, (d) SiO<sub>2</sub>, (e) feldspar, (f) Na<sub>2</sub>O and (g) borax were studied for luster, degree of emulsification, shrinkage, bubbles and cracks produced in the product after baking at about 800°. The chem. compn. of these combinations was calcd. from the amts. of ingredients used in the mixt. and is given in a table. Results: *Luster*.—samples contg. (a) and (c) were inferior to those contg. (b). The ones contg. much basic constituents, i. e. (f) and (e) gave poor luster. *Emulsification*.—The influence of compn. on the degree of emulsification was very slight. Samples contg. much (a) gave products of low quality, while ones contg. (a), (b) and (c) together gave the best results. Samples contg. excess of (f) and (g) gave very poor results, and the ones contg. basic constituents gave poor emulsification, which is contrary to the usual conception. *Shrinkage*.—When (a), (b) and (c) were present together, good products were obtained. With increase in acid constituents products of lower grade were obtained. *Bubbles*.—With increase in basic constituents inferior products resulted. *Cracks*.—An increase in (c) gave more cracks, while an increase in basic constituents seemed to improve the products. NAO UYEI

Ceramics of highly refractory materials. II. The system: ZrO<sub>2</sub>-CaO (RUFF, *et al.*) 2. Heating or burning porcelain (U. S. pat. 1,713,834) 9.

Glass. IMPROVED GLASS PROCESS, INC. Fr. 651,985, Mar. 30, 1928. BaSO<sub>4</sub> is added to the constituents of glass to give a brilliant and easily worked glass. The addn. is sufficiently small to avoid the formation of foam or of a molten layer of sulfate on the glass. Decolorization may be effected by a substance contg. Se, Mn, etc.

Glass. IMPROVED GLASS PROCESS, INC. Fr. 652,036, Mar. 31, 1928. The BaSO<sub>4</sub> of Fr. 651,985 (cf. preceding abstr.) is replaced by BaS, which may be obtained by reduction of BaSO<sub>4</sub>, residues of BaSO<sub>4</sub> diminishing the formation of foam during the fusion.

Distributor for molten glass from the furnace. ALFRED BOUCHER. Fr. 33,709, Mar. 19, 1927. Addn. to 640,854 (*C. A.* 23, 945).

Glass-making crucibles. SOC. MAGNIER FRÈRES (S. A. R. L.). Fr. 652,414, Apr. 10, 1928.

Decorating glass. J. T. FELL and J. FELL. Brit. 300,070, March 15, 1928. The

glass to be decorated is placed in contact with sprinkled "floating cellulose colors" (cellulose varnish and pigments) to pattern the under side of the glass (parts of which may be preliminarily covered with paper, etc., to form a design) and any uncovered portions of the surface may be coated with other decorative materials. A backing of rubber soln. or other material may be applied.

**Forming blown "bubble" or "blister" glassware.** REUBEN HALEY. U. S. 1,715,130, May 28. Mech. features.

**Glass articles with lines of strain to facilitate division of the articles.** FELIX MEYER. U. S. 1,713,854, May 21. An internal strain is developed along a division line of an article such as a sheet or bottle in order to facilitate subsequent intentional breakage along the line without splintering.

**Annealing leer for glassware.** PERCY Q. WILLIAMS (to Owens Bottle Co.). U. S. 1,714,707, May 28.

**Apparatus for annealing glass objects.** THE AMSLER-MORTON CO. Fr. 652,117, Apr. 3, 1928.

**Coloring glass electric lamp bulbs.** M. PIPKIN (to British Thomson-Houston Co., Ltd.). Brit. 300,179, Nov. 7, 1927. In a method such as described in Brit. 277,695 (C. A. 22, 2518) pigments are used on the frosted surface comprising  $\text{WO}_3$  or comprising a mixt. of a finer and a coarser powder, which may include oxides, sulfides and silicates of Fe, Cd, Cr, Co, Se, Ti, W and Zr. Red P may be added as a "getter." Cf. C. A. 23, 3321.

**Composite sheets of glass and celluloid or cellulose acetate.** P. H. HEAD. Brit. 299,900, July 30, 1927. Diacetone alc. is used alone or in soln. to cause adhesion between glass sheets of celluloid or cellulose acetate. Denatured alc. may be added as may also  $\text{C}_2\text{H}_2\text{Cl}_4$ , acetone,  $\text{C}_2\text{HCl}_3$ , methyl cyclohexanone, or cyclohexanone. The glass is preferably preliminarily cleaned with diacetone alc., and a sugar soln. contg. a small addn. of  $\text{HNO}_3$  also may be used to assist cleaning and adhesion.

**Gas-forming materials for producing porous bricks, insulation, etc.** M. PLATSCH. Brit. 299,854, Nov. 2, 1927. Gas-liberating substances such as  $\text{CaC}_2$ , Ca hydride and ferro-Si (such as are suitable for use in the manuf. of light bricks, insulating and abrasive materials) are coated with glue, gelatin, water glass, or the like to retard their action.

**Burning ceramic ware.** TAINÉ G. MCDUGAL (to A. C. Spark Plug Co.). U. S. 1,713,851, May 21. The ware is heated in a kiln while exposed on substantially all sides to direct radiation from the walls of the kiln to which heat is applied. A kiln construction is described. U. S. 1,713,852 also relates to a tunnel kiln construction.

**Chrome refractory brick.** RUSSELL P. HEUER (to General Refractories Co.). U. S. 1,714,506, May 28. In making a chrome refractory brick from clay and chrome ore contg. combined magnesia, a body of chrome ore is treated with a small quantity of clay and magnesia in sufficient quantity to prevent softening reaction between the clay and chrome ore at high temps.; a soln. of a salt such as  $\text{MgCl}_2$  or  $\text{MgSO}_4$  which will yield Mg ions in the mixt. is also added.

**Refractory material suitable for lining metal molds for casting metals.** HARRY M. WILLIAMS (to General Motors Research Corp.). U. S. 1,713,580, May 21. At least a substantial portion of a non-oxidizable refractory material such as  $\text{MgO}$ , zirconia,  $\text{SiO}_2$ ,  $\text{Al}_2\text{O}_3$ , or thoria is reduced to an impalpable powder in the presence of an alkali, tannic acid, or other suitable deflocculating agent; the powdered material is formed into the desired shape and is heated to effect coherence.

**Composition for use as a furnace cement, etc.** RALPH M. HARDGROVE (to Fuller Lehigh Co.). U. S. 1,714,598, May 28. Pulverulent heat-cond. material such as  $\text{SiC}$  is mixed with water glass, glycerol and castor oil or other suitable oil to form a product which is substantially non-porous when dry.

**Abrasive wheels.** BIRMINGHAM SMALL ARMS CO., LTD., A. R. PAGE and P. S. DEVEREUX. Brit. 299,633, Dec. 16, 1927. Abrasive segments clamped around a central rotary member have the interstices between them filled with a plastic material, which sets so as to have a character similar to that of the material of the segments. A mixt. of  $\text{MgO}$ , abrasive grit and  $\text{MgCl}_2$  soln. may be used for this purpose.

## 20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

**Standard specification for concrete and reinforced concrete.** *Can. Eng. Standards Assoc.* No. A23, 149 pp. (1929). E. I. S.

**A new process of burning portland cement.** K. BEHL. *Cement, Mill and Quarry*

34, No. 5, 40-2(1929).—New design of shaft kiln avoids sticking and hanging of charge. Photomicrographic characteristics of clinkers for rotary, ordinary shaft and newly designed shaft kilns are given. E. I. S.

Blending Fresno pumicite with cement. J. B. LIPPINCOTT. *West. Construction News* 4, 243-6(1929).—Fresno pumicite is unique on account of its extreme fineness and uniformity, which should give to it greater cementaceous properties than coarser materials of the same chem. properties. Chem. and sieve analyses and setting time and strength heats are given. E. I. S.

New wet-process cement plant. C. G. THORNBURGH. *Cement, Mill and Quarry* 34, No. 5, 13-7(1929).—The Davison Coke and Iron Co., Pittsburgh, Pa., is building a combination by-product coke plant, blast-furnace and wet-process cement plant. The surplus gas from coke plant will be utilized in the kilns. The blast-furnace plant will supply granulated slag which with limestone, clay or shale will constitute the raw material for cement manuf. E. I. S.

Experiments with concrete mixing machines. A. BONWETSCH. *Tonind.-Ztg.* 53, 746-8(1929). F. O. ANDEREGG

Compressive and flexural strengths of concretes having varying water-cement ratios, fineness moduli and maximum aggregate size. M. GENEL. *Beton u. Eisen* 28, 184-8(1929). F. O. ANDEREGG

Setting temperatures in concrete bridge piers. A. A. JAKKULA. *Eng. News-Record* 102, 913-4(1929).—Temp. of atm., of area surrounding the concrete, which was enclosed with tarpaulins and heated by salamanders, and of the concrete itself during setting of piers of Cedar Ave. bridge, Minneapolis, Minn., constructed in winter, are shown graphically. A rise of 30-50° F. can be expected in large masses of concrete if suitably protected. Canvas and salamander protection is satisfactory. R. E. T.

Better curing raises core strength of concrete pavement base. M. D. WILSON. *Eng. News-Record* 102, 827(1929).—Control of the mix and improvements in the methods employed for curing the concrete pavement base in Akron have resulted in an increase in strength in excess of 400% since 1923 without increase in cost. During 1928 the curing procedure consisted of covering with wet burlap for the first 24 hrs. and with wet straw for the following 6 days. The mix employed is 1:7½. Allowance for bulk-ing will be made in 1929. R. E. THOMPSON

Standard cement concrete pavement opened in 48 hours. EARLE W. MECKLEY. *Eng. News-Record* 102, 871(1929).—A description of the methods employed in laying a concrete pavement in Allentown, Pa., which was opened for traffic 2 days after placing. The mix employed was 1:2:3, with a 1¼ min. mixing period and just sufficient water to permit satisfactory working. CaCl₂ was added to the mix at the rate of 2 lbs. per bag of cement. The concrete was cured by covering with wet burlap. The compressive strengths at the ages of 1 to 7 days are shown graphically. The av. 48-hr. strength was 2260 lbs. per sq. in. R. C. THOMPSON

Deterioration of concrete and its protection by means of surface coatings. RICHARD GRÜN. *Tonind.-Ztg.* 53, 382-4, 699-701, 716-8(1929); cf. C. A. 22, 3030; 23, 2800. —The properties of importance in protective coatings include: sp. gr., spreadability and yield, viscosity, drying capacity, covering strength and appearance, elasticity and denseness, also behavior against phys. actions, including cold, ultra-violet light, wet and dry heat. Coatings should stand up against the chem. action of O₃, H₂SO₃ (both hot and cold), H₂SO₄, HCl, HOAc and NaOH. F. O. ANDEREGG

The formation of two different calcium sulfoaluminates from the gypsum in cement. P. MECKE. *Tonind.-Ztg.* 53, 681-4(1929).—As a result of the reaction of Ca(OH)₂ and aluminate on the sulfoaluminate, 3CaO.Al₂O₃.3CaSO₄, another salt, 3CaO.Al₂O₃.2CaSO₄, is formed which has different crystal structure and optical properties and is of different resistance to NaOH and Ca(OH)₂ solns. The first salt does not remove the SO₃ completely from soln., some 40% being left, while the latter apparently does. The second form is regarded as more stable. (Cf. Lerch, Ashton and Bogue, C. A. 23, 3180, whose more careful work does not agree with that of M.) F. O. A.

The effect of steam treatment of portland cement mortars on their resistance to sulfate action. T. THORVALDSON AND V. A. VIGFUSSON. *Eng. J. (Can.)* 11, No. 3, 174-9(1928); *Expt. Sta. Record* 59, 377; cf. C. A. 22, 4753. —Expansion measurements of portland cement mortar bars were used to study the effect of steam treatment of mortars on their resistance to the action of the sulfates of Mg, Na and Ca. Treatment of mortars with satd. water vapor at 50° reduced their resistance to sulfate action. Satd. water vapor at temps. of 75° or above increased the resistance. The higher the temp. the more effective was the treatment and the shorter the time of treatment required. Steam treatment of mortars at the boiling point of water made them practi-

call completely resistant to the action of  $\text{Na}_2\text{SO}_4$  solns. and very materially increased their resistance to the action of  $\text{MgSO}_4$  solns. Immersion of mortars in hot water was nearly as effective in increasing the sulfate resistance as was treatment with steam at the same temp. The addn. of tricalcium aluminate to portland cement speeded up the rate of expansion of its mortar in solns. of the sulfates of Na, Mg and Ca. Steam treatment of these mortars was not as effective in preventing expansions in solns. of Na and Ca sulfates as was steam treatment of mortars from the same cement without the addn. of tricalcium aluminate. It is suggested that the greatly increased resistance to sulfate action brought about by steam treatment of portland cement mortars is primarily due to the action of the steam on the aluminate in the cement. The speeding up of the hydration of the silicates by the steam treatment, while increasing the strength, is considered to be probably of secondary importance in relation to sulfate resistance.

H. L. D.

**Is the filling of architectural terra cotta with concrete necessary or desirable?** M. BARRETT. *Trans. Ceram. Soc. (Eng.)* 28, 79-82 (1929).—Concrete filling is considered unnecessary for terra cotta since so little gain in strength results and disruption of the unit may occur because of unequal expansion and contraction of the 2 materials.

H. F. KRIEGER

**Investigations on breeze and clinker aggregates.** F. M. LEE. Dept. Sci. Ind. Research (Brit.), *Building Research Tech. Paper No. 7*, 86 pp. (1929); cf. *C. A.* 22, 1452.—The properties of breeze or clinker when used as concrete aggregate are detd. by the amt. and character of the combustible matter present. Failure of breeze and clinker concretes is usually due to the presence of certain types of coal which are dangerous to concrete by reason of the expansional movements they produce during the setting period and early life of the concrete. Coals may be divided into 3 classes: (A) those which are not dangerous; (B) those with intermediate properties; (C) those which cause cracking of concrete when present in relatively small quantities. Class (B) and (C) coals have a higher O content than class (A) coals and display higher sorptive power for moisture. Class (C) coal has a high sorptive power for methylene blue. Class (B) and (C) coals absorb O more rapidly than class (A) coal. Decompn. of coals by heating at temps. of  $500^\circ$  or above decreases the dangerous properties of any coal. Oxidation of a coal at lower temps. increases its dangerous properties. Failure of breeze or clinker concretes due to the presence of S compd. appears to be rare. The limiting S content which may safely be present is dependent on its phys. state. The following amts. may safely be permitted: S as sulfide—not above 0.45%; S as sulfate—not above 0.4% S; total S excluding that present as sulfate—not above 0.75%. Considerably higher contents may be permitted when the S compds. are sintered or fused. A breeze contg. more than about 40% combustible matter will give only a very low-grade concrete, whatever the nature of the combustible matter. RAYMOND WILSON

**Relation between the temperature curve and the expansion curve in the setting of plaster of Paris.** F. J. WILLIAMS AND F. C. WESTENDICK. *J. Am. Ceram. Soc.* 12, 377-81 (1929).—The first vol. change is a contraction, probably due to a soln. of  $\text{CaSO}_4 \cdot \frac{1}{2}\text{H}_2\text{O}$ . The expansion which follows is due to crystn. of  $\text{CaSO}_4 \cdot \text{H}_2\text{O}$ . Curves are given for both temp. and expansion.

C. H. KERR

**The factors of the fireproofing of wood.** A. GILLET. *Chimie & industrie Special No.*, 221-7 (Feb., 1929).—After discussing the influence of the various factors involved in the ignition and combustion of wood, G. gives the results he obtained in tests carried out with  $(\text{NH}_4)_2\text{HPO}_4$ ,  $\text{Na}_2\text{SiO}_3$ ,  $\text{NH}_4\text{Cl}$ ,  $(\text{NH}_4)_2\text{SO}_4$ ,  $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ ,  $\text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O}$ ,  $\text{NH}_4\text{BO}_2$ ,  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ ,  $\text{CuCl}_2$  (5% and 20%),  $\text{Al}_2(\text{SO}_4)_3 \cdot 18\text{H}_2\text{O}$ ,  $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$ ,  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ ,  $\text{NH}_4\text{Cl} + \text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$ ,  $\text{NaNH}_2\text{HPO}_4$ ,  $(\text{NH}_4)_2\text{SO}_4 + (\text{NH}_4)_2\text{HPO}_4$ ,  $(\text{NH}_4)_2\text{SO}_4 + \text{NH}_4\text{BO}_2$ ,  $(\text{NH}_4)_2\text{SO}_4 + \text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ ,  $\text{Fe}(\text{SO}_4)_3 \cdot (\text{NH}_4)_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$ ,  $\text{MgCl}_2$ ,  $\text{NH}_4\text{Cl} \cdot 6\text{H}_2\text{O}$ ,  $\text{NH}_4\text{Cl} + \text{Zn}(\text{BO}_2)_2$ ,  $\text{Na}_2\text{SiO}_3 + \text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O}$ . The tests were carried out by immersing air-dried blocks  $4 \times 4 \times 45$  mm. for 3 days in a 20% soln. of the salt and detg. the wt. of impregnating substance absorbed, the calorific value of the impregnated wood, the vol. of vapors given off at  $650^\circ$  by a given wt. of wood, studying the carbonization and the flame of the gases evolved, examg. the combustibility of the charcoal and testing local inflammability. The results of the tests are briefly discussed; but no general conclusions are drawn, as the tests are only preliminary. A. P.-C.

Rubber floor and wall coverings, etc. (Brit. pat. 300,008) 30.

**Cement from slurry.** JOHN E. VELZY and WALTER T. GRONER (to Southwestern Portland Cement Co.). U. S. 1,714,060, May 21. After delivery and mixing of lime

slurry, water is added in the mixer, the slurry is mixed centrifugally with waste dust, the dust and lime slurry are subjected to whirling, and the mixt. is conveyed and further mixed as it is delivered to a cement mill. An arrangement of app. is described.

**Aging calcined gypsum.** SAMUEL G. MCANALLY. U. S. 1,713,879, May 21. Moisture is directly applied in the proportion of about 70 lbs. water per ton of calcined gypsum, while agitating the material.

**Treating by-product calcium sulfate from phosphoric acid manufacture.** ROBERT S. EDWARDS (to Rumford Chemical Works). U. S. 1,713,868, May 21. The mass is subjected to grinding in water in a continuous process, in the presence of a neutralizing compd. until a completely hydrous and blended neutralized product is produced, which is suitable for use as a plaster.

**Artificial stone.** SOC. ANON M. A. P. Fr. 652,195, April 4, 1928. Artificial stone is made from cryst.  $\text{CaCO}_3$ , a binding agent such as  $\text{CaSO}_4$ , and colloidal  $\text{SiO}_2$ .

**Bituminous material for roads.** W. H. SCHMITZ. Brit. 300,196, Nov. 8, 1927. Aggregate is first wetted with an alkali soln. and then treated with a bituminous emulsion. Cf. C. A. 23, 2547.

**Building material.** VICTOR C. J. NIGHTINGALL. Australia 13,096, May 2, 1928. A cellular building material with soundproof and insulating properties is made by mixing plaster of Paris,  $\text{CaCO}_3$  and an acid such as oxalic acid. It may be reinforced with fiber or other material.

**Building material.** ENRIQUE D. ROLANDO. Fr. 652,339, April 6, 1928. A material which may replace wood or Fe is composed of a mixt. of pumice stone and a binding agent (lime, cement, silicate, etc.) with or without  $\text{MgO}$  and may be made in the cold or with heat and pressure.

**Asphalt, etc.** I. G. FARBERIND. A.-G. Fr. 652,114, April 3, 1928. Bituminous emulsions for use on roads, etc., are made with water and materials contg. insol. humic acid or substances having the character of this acid.

**Coating roofing felt or paper.** JOHN C. BLACK and WIRT D. RIAL (to Pan American Petroleum Co.). U. S. 1,714,206, May 21. A body of melted asphalt is protected from any substantial oxidation by displacing any air in it by introduction of a non-oxidizing gas such as a stored combustion gas mixt. and the asphalt is kept at a temp. of about  $200^\circ$  by heating and circulating it through a pipe system and regulated quantities of the asphalt are introduced into a coater tank to maintain a constant level in the tank through which the material to be coated is passed.

**Waterproof and flame-resistant building paper.** Otto A. Frederickson (to Wire-Mold Co.). U. S. 1,715,080, May 28. A relatively thick sheet of paper has one face with a waterproof and flame-retarding coating of stearin pitch adapted to blister when exposed to fire, with an overlying thin coating of paraffin to give a smooth non-sticky surface.

**Wall board.** UPSON CO. Brit. 300,041, Dec. 30, 1927. Wall boards which may be faced with paper are formed by admixture of an intumescent binder such as a sol. alkali silicate, hide glue or corn starch with a filler such as powdered dolomite and sawdust and heating the mixt. to form a porous rigid mass. Various details and an arrangement of app. are described.

**Apparatus for forcing impregnating liquid into wood.** R. STEINFELD. Brit. 299,842, Nov. 2, 1927. Structural features.

## 21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER

**New fuel research laboratories at Ottawa.** B. F. HAANEL. *Engineer* 147, 160-1 (1929).—The permanent equipment will include by-product recovery coke plant, a powd.-fuel steam-generating plant, a briquetting plant, all on the com. scale, a large-scale coal-working plant and an exptl. domestic heating plant. D. B. DILL

**Average qualities of Russian fuels.** A. K. BESYADOVSKII. *Izvestiya Teplolekhn. Inst. (Trans. Thermo-Tech. Inst. (Moscow))* 1928, No. 10, 77-85.—Very complete data are given on coals from Donetz, Moscow, Ural, Kuznetskii, Minusinskii, Chermkovskii, Eastern Siberia and Suchanskii. A. A. BOERTLINGK

**Investigations on liquid fuels.** V. IPAT'EV. *Chimie & industrie Special No.*, 115-22 (Feb., 1929).—An address reviewing the progress accomplished during the last 15 yrs. in the production of liquid fuels from raw materials other than petroleum. A. P.-C.

**Soft coal as a source of liquid fuels.** RENÉ CHAUX. *Rev. sci.* 67, 5-16 (1929).—A

review of the work done in this field: high- and low-temp. carbonization, hydrogenation, tar treatment and gasification. P. THOMASSET

**Terminology in coal research.** REINHARDT THIESSEN AND WILFRID FRANCIS. *Bur. Mines, Tech. Paper 446*, 27 pp. (1929). E. H.

**A chemical engineering view of coal processing.** H. C. PARMELEE. *Proc. 2nd Intern. Conference Bituminous Coal 1*, 133-8 (1928). E. H.

**Coal cleaning problems of today.** K. GLINZ. *Proc. 2nd Intern. Conference Bituminous Coal 2*, 22-36 (1928). E. H.

**The chemical utilization of coal.** FRITZ ROSENDAHL. *Metallbörse 19*, 397-8, 455-6, 510-12, 622-4, 678-80, 733-5 (1929).—An attempt to cover in one article (1) the constitution of coal, (2) low- and high-temp. distn. of coal, (3) application of the gases for the synthesis of hydrocarbons and fertilizers, (4) liquid fuels: benzene, alc., hydro-naphthalene, (5) production of oils without coking. Conclusion: The direct utilization of coal for the production of valuable products is still an unsolved problem, but the new processes for combining CO, CO<sub>2</sub> and H obtained from coal, low-temp. distn., high-temp. distn., and the indirect treatment of coal and its products by catalysts, have already proved their worth. W. C. EBAUGH

**Some recent developments on the constitution of coal.** REINHARDT THIESSEN. *Proc. 2nd Intern. Conference Bituminous Coal 1*, 695-767 (1928). E. H.

**Inorganic constituents of coal.** SZ. HANKISS. *Szénkísérleti Közlemények 2*, 134-9 (1928); *Chimie & industrie 21*, 721.—Various finely ground coals were extd. successively with H<sub>2</sub>O and 2 and 10% HCl. Mäza coal yielded only a small quantity of ext. (about 4% of the wt. of ash), from which it is concluded that the inorg. matter of this coal consists chiefly of insol. silicates. Pécs coal gave about 3% of ext. (equiv. to about 15% of the ash); the ash of the original coal was red, and that of the extd. coal white, showing that the whole of the Fe was dissolved; quant. analysis showed most of the Fe was present in the form of pyrites, the H<sub>2</sub>O ext. contg. a little FeSO<sub>4</sub> due to oxidation. The S extd. amounted to 40% of that present in the coal and to 1% of the coal; the aq. ext. contained only small quantities of alk. silicates; the Mg and Ca compds. are of but little importance. A. PAPINEAU-COUTURE

**The coal industry and the analysis of coals.** M. DOLCH. *Z. Oberschles. Berg- u. Hüttenmann. Ver. Katowice 68*, 64-72 (1929); *Chimie & industrie 21*, 722-3.—H<sub>2</sub>O can be detd. in about 10 min. by treating the coal with abs. alc., distg., adding an equal vol. of petroleum to a suitable aliquot and detg. the turbidity pt. H<sub>2</sub>O, tar, gas and coke can be detd. on the same sample as follows: place the sample in a Fischer steel retort in an elec. furnace, dry in a current of CO<sub>2</sub> or N, collecting the H<sub>2</sub>O; heat to 530°, collecting the gas and primary tar; finally heat to 1000° to obtain the coke. The ordinary method of reporting results is not suitable for technical purposes, and it would be preferable to report the distribution of the latent heat in the 3 phases of the fuel, as it would allow of predicting with greater certainty the phenomena which would take place on gasifying; when the gaseous phases of such dissimilar fuels as bituminous coal and lignites are considered, in this manner it is surprising to find that they give figures of the same order. D. also shows the advantage of detg. the max. CO<sub>2</sub> content of total combustion gases, from which the importance of the ultimate decompn. in the presence of steam can easily be obtained, as well as the amt. of gas due to the cracking of the tar; the amt. of H produced by the H alone can also be found. A. PAPINEAU-COUTURE

**Locomotive coal tests.** J. G. B. SIMS. *Engineer 147*, 244 (1929).—Details are given of tests using *Welsh, Pocahontas and New River coal*. The av. coal consumption per ton mile was, resp., 0.242, 0.271 and 0.264 lb. D. B. DILL

**The past, present and future of Illinois coal.** S. W. PARR. *Am. Iron and Steel Inst.* (advance paper) 1929, 23 pp.—Historical notes with review of modern practice and conditions. The future of Illinois coals holds decided promise for manuf. of both coke and gas. E. I. S.

**The composition of a Permi-Carboniferous coal in North China.** K. ASADA. *Bull. Geol. Soc. China 7*, 185-9 (1928). (In English.) E. I. S.

**Coal from the Yakutsk mining district.** N. M. KARAVAYEV AND I. B. RAPOPORT. *Izvestiya Teploekkh. Inst. (Trans. Thermo-Tech. Inst. (Moscow)) 1928*, No. 10, 32-43.—Coal from Sangarui contains 4.25-9.5% H<sub>2</sub>O, 10% ash (on dry coal), S very low, volatile matter 40-54%; its heating value is 7359-8100 cal./kg. The elementary compn. is C 75.4-81, H 5.5-6.4 and N up to 1%. This coal is suitable for low-temp. carbonization; it belongs to class II according to Gruner's classification. Coal from the Zhiganui area has up to 20% H<sub>2</sub>O, 13-15% ash (on dry coal), 0.3-0.35% S, 45.5-48.5% volatile matter, 6900 cal./kg. heating value, 69-71.3% C, 4.77-5.5% H. It is unsuitable for

low-temp. carbonization. The Buluk area has hard and brown coal (analysis not given).

A. A. BOEHLINGK

**Oxidation of Moscow coal in a stream of air oxygen at various temperatures.** N. M. KARAVAYEV AND A. K. IVANOV. *Izvestiya Teplolekhn. Inst. (Trans. Thermo-Tech. Inst. (Moscow))* 1928, No. 10, 44-50.—Twenty-five g. each of Shchekinskii coal and Bobrinskii coal were heated to 60°, 80°, 110°, 140° and 180° in a container immersed in an oil bath in a stream of air (a total of 30 l.). The oxidation reaction is of two types, i. e., the addn. of O and the splitting off of some products of decompn. or oxidation. Bobrinskii coal absorbed O very slowly at the lower temps.; the absorption increased considerably in the neighborhood of 180°. Shchekinskii coal absorbed O at an approx. steady rate. The decrease in C and H with increasing temp. is higher for Bobrinskii coal. At 110° an appreciable chemical change has begun; so this temp. is too high for H<sub>2</sub>O detns. Both coals lose 10-14% of their heating value when preheated to 180°. Marcasite, which by some authors is considered as the cause of self ignition, was not detected in these coals. The carbonyl O (2.65 and 2.15% at ordinary temp.) increased to 3.46 and 3.09% at 180°. Bobrinskii coal, then, takes up O at a temp. below 80°, while Shchekinskii coal takes up O below 140°. The amount of CO found in the products of oxidation increases with the increase in temp. H. decreases more rapidly than C. The carbonyl O increases with increase in temp.

A. A. BOEHLINGK

**The binding power of coal extract.** SZ. HANKISS. *Szénkísérleti Közlemények* 2, 161-5(1928); *Chimie & industrie* 21, 722.—Extn. of 2000 g. of Tata coal for 30 hrs. with 6 l. of a mixt. of EtOH and C<sub>6</sub>H<sub>6</sub> gave 9.8% of ext. which was fairly plastic under high pressure, the extd. coal contg. 0.75% of residual bitumen. Briquets prepd. by mixing the extd. coal with 0.75-18.4% of the ext. at 70° and briquetting in a hydraulic press at 1500 atm. proved unsatisfactory. Pécs coal was extd. under pressure; the unextd. coal gave better briquets than the extd. coal; addn. of ext. improved the quality of the briquets. H. considers that the quality of the briquets depends primarily on the phys. condition of the coal (state of subdivision, H<sub>2</sub>O, temp. and pressure) and on the humic compds., bituminous compds. playing a secondary role.

A. P.-C.

**Commercial aspects of low-temperature coal distillation by the International Bitumenol Corporation process.** J. N. VANDEGRIFT. *Proc. 2nd Intern. Conference Bituminous Coal* 1, 546-59(1929).

E. H.

**Low-temperature carbonization of coal under pressure.** B. MORY. *Szénkísérleti Közlemények* 2, 96-8(1928); *Chimie & industrie* 21, 724.—If there is no suitable market for the pitch sepd. in the distn. of primary tar, the pitch can be practically eliminated by carbonizing the coal under pressure so as to crack the primary tar into lighter compds. Carbonization at 510° and 10 atm. of Gyöngyös lignite (H<sub>2</sub>O 35.76, ash 12.32%) gave only 2.5% of distillate, instead of 5% at atm. pressure; but the pressure distillate contained more C<sub>6</sub>H<sub>6</sub>.

**Low-temperature carbonization of blended New Zealand coals.** W. G. HUGHSON. *New Zealand J. Sci. Tech.* 10, 263-74(1929).—The Gray-King assay as described in the Great Britain Fuel Research Survey of Natural Coal Resources, No. 7 (C. A. 21, 2780) has been used to det. the behavior of New Zealand coals when subjected to low-temp. carbonization. Tabulated results on 55 brown, bituminous and blended coals are given.

A. S. CARTER

**Low-temperature distillation of Moscow soft coals and the analysis of tar and gas.** G. L. STADNIKOV. *Izvestiya Teplolekhn. Inst. (Trans. Thermo-Tech. Inst. (Moscow))* 1928, No. 10, 96-8.—Bobedinskii coal was heated to 500° (1) in an aluminum retort, (2) in Graefe's retort and (3) in Fischer's rotating aluminum retort. The products (in %) of (1) and (2), resp., were total water 36.1, 36.2; water of decompn. 4.0, —; semi-coke 50.7, 48.4; tar 6.6, 4.8; gas, 6.6, 9.9; gas with H<sub>2</sub>S —, 4.7; total H<sub>2</sub>S —, 1.3. The gas from (2) contained CO<sub>2</sub> 28.2, C<sub>2</sub>H<sub>4</sub> 2, CO 10.6, CH<sub>4</sub> 17.2, H<sub>2</sub> 39.0 and N<sub>2</sub> 3.0%; heating value was 3,261 cal./kg. In (3) 20 kg. coal produced 17.4% ash, 32.1% moisture, 0.8% light oil, 1.5% heavy oil, benzene-extd. oils from dust 0.93%, H<sub>2</sub>O-free tar 3.3%, semi-coke 52.4%, coal dust 10.0%. The tar fractions were 0.7% below 100°, 6.24% at 100-150°, 6.39% at 150-200°, 9.49% at 200-250°, 18.85% at 300-350° and residue above 350° 20%. It contained phenols 18.7%, crude paraffin wax 5.55% and asphaltenes 11.8%. The tar contained coal dust and water which was extremely difficult to separate. This coal is not suitable for low-temp. carbonization.

A. A. BOEHLINGK

**The coking test of coal.** T. SHIMMURA. *J. Fuel Soc. Japan* 8, 379-85(1929).—In

order to study the coking properties of coal S. tested nearly 50 kinds of Japanese and Chinese coals, using Lessing's coking app. The strongly coking coal gave a swollen coke of mushroom appearance and black in color, while the coke from weakly coking coal has a gray color with no metallic luster; the vol. of the coke is less than that of the coal. In order to study the relation of the swelling property and the mushroom appearance of the coke to the coking constituents of the coal, S. extd. from coal  $\alpha$ ,  $\beta$  and  $\gamma$  compds., and carbonized these compds. in L.'s coking app. The  $\alpha$  compd. gave a black, powder coke. The  $\beta$  compd. of certain coals swelled but gave no mushroom appearance, and in other coals a black powder coke similar to the  $\alpha$  compd. resulted. The  $\gamma$  compd. of all kinds of coals fused easily and produced a black flake of mushroom appearance. The analysis of gas produced in L.'s coking app. shows that the weakly coking coal is rich in  $\text{CO}_2$  and CO and poor in satd. and unsatd. hydrocarbons. F. I. NAKAMURA

**The briquetting of Pécs coal.** SZ. HANKISS AND ST. PETER. *Szénkísérleti Közlemények* 2, 156-60(1928); *Chimie & industrie* 21, 722.—Because of its high adhesive power and swelling properties Pécs coal can give good briquets directly. It begins to decomp. at about  $280^\circ$ , is very adhesive at about  $300^\circ$  and completely softened and plastic at  $350$ – $450^\circ$ . The swelling and distn. of the tar also take place at about  $400^\circ$ . Above  $400^\circ$  the decompn. becomes more quiet and at  $500^\circ$  the coal becomes hard again. The content of agglutinating matter is very low (about 0.5%), the moisture content 10% and ash 23%. By using a high pressure (about 1500 atm.) briquetting can be carried out at a much lower temp. (about  $100$ – $50^\circ$ ). The briquets thus prepd. are quite strong and resistant to the action of water; their adhesion is decreased about 15–20% after exposing to sunlight for about 6 weeks. The briquets are very compact, ignite readily, and burn with a min. of smoke and soot and clinkering. A. PAPINEAU-COUTURE

**Fixation of sulfur in coal briquets.** R. KADA AND K. OGATA. *J. Fuel Soc. Japan* 8, 414-28(1929).—Fixation of sulfur to prevent disagreeable fumes in the use of coal briquets for domestic fuel was studied.  $\text{CaO}$ ,  $\text{CaCO}_3$ ,  $\text{MgO}$ ,  $\text{Na}_2\text{CO}_3$ , Eschka mixt. and  $\text{BaCO}_3$  were used for the fixation of S. Lime is the best agent; it fixes about 60–80% of total S at  $700$ – $900^\circ$ . Catalysts such as  $\text{Fe}_2\text{O}_3$ ,  $\text{MnO}_2$  and  $\text{ZnO}$  were employed.  $\text{Fe}_2\text{O}_3$  shows the best result; the reaction takes place at  $450$ – $650^\circ$ . Addn. of 1–2% of  $\text{Fe}_2\text{O}_3$  with slaked lime gave almost 100% fixation of S. F. I. NAKAMURA

**Manufacture of coal and lignite agglomerates.** CH. BERTHELOT. *Tech. moderne* 21, 173-9, 204-6(1929).—Modern methods of the manuf. of these products are described. P. THOMASSET

**Modern developments in lignite carbonization.** F. P. KERSCHBAUM. *Proc. 2nd Intern. Conference Bituminous Coal* 1, 283-302(1928). E. H.

**Drying lignites under pressure.** B. MORV. *Szénkísérleti Közlemények* 2, 140-4(1928); *Chimie & industrie* 21, 721; cf. C. A. 23, 2012.—Lignites from Gyöngyös ( $\text{H}_2\text{O}$  40%), Mucsony ( $\text{H}_2\text{O}$  25%) and Sajóvölgy ( $\text{H}_2\text{O}$  30%) were heated in an autoclave at 8–12 atm. for 1.5–2.5 hrs. and the surface moisture was then allowed to evap. The amt. and m. p. of the ash were reduced, and the C content, H content and calorific value of the dry lignite were increased. The yield of tar was unchanged and the coke obtained from the dried lignites was less friable. A. PAPINEAU-COUTURE

**The effect of a liquid dispersion medium on the treatment of semi-coke and lignite with hydrogen at high temperature and pressure.** H. I. WATERMAN AND J. S. DOTING. *Chimie & industrie Special No.*, 218-20(Feb., 1929).—At a temp. of  $423^\circ$  and under a pressure of about 7 atm. (measured cold), semi-coke from lignite absorbs only a very small quantity of H; paraffin (from Rangoon petroleum) absorbs quite an appreciable quantity of H; semi-coke from lignite in presence of paraffin absorbs a considerably larger proportion of H than in the absence of paraffin. By substituting activated charcoal (norite E and carboraffin) for the semi-coke in presence of paraffin, the H absorption was practically the same as that with the paraffin alone, showing that the semi-coke actually absorbs H and does not merely act as a catalyzer toward the hydrogenation of the paraffin. A. PAPINEAU-COUTURE

**New considerations on the use of carbon as an economic substitute fuel (for automotive engines).** A. CHARLES ROUX. *Chimie & industrie Special No.*, 213-7(Feb., 1929); cf. C. A. 22, 3757, 4231.—From a discussion of the problem from both technical and economic standpoints, R. considers that the solution of the problem is in using a mixt. of wood charcoal and semi-coke from the low-temp. carbonization of coal, agglomerated by means of a peat product (the exact nature of which is not stated), which could be produced at approx. the same cost as wood charcoal. A. P.-C.

**Study of the possibility of using wood carbonized at low temperature as a fuel in gas producers (for motor vehicles).** G. DUPONT, J. L. LUSSAUD AND J. ALLARD. *Ann. combustibles liquides* 3, 553-5(1928). I. Study of the distillation of various woods at

different temperatures. *Ibid* 555-75. II. Tentative theory of the gasification of wood charcoal to determine the most suitable carbonization temperature. G. DUPONT. *Ibid* 576-90.—See C. A. 23, 2551. R. E. SCHAAD

Heat efficiency of a domestic heating stove. M. KUROKAWA. *J. Fuel Soc. Japan* 8, 386-97(1929).—The temp. and compn. of exit gas, humidity and temp. of inlet air were observed every 20 mins. and the heat balance was calcd. from the mean values. Charcoal gave the highest efficiency followed by gas coke, Tsuzura semi-coke and anthracites. The thermal loss due to excess air, the moisture in flue gas, incomplete combustion and the unburned matter in the ash are also discussed. F. I. NAKAMURA

Present day methods of extraction of pyridine bases. CH. AB-DER-HALDEN. *Chimie & industrie* 21, 708-10(1929).—A brief review of the  $C_5H_5$ , steam distn., and  $Na_2CO_3$  methods for the extn. of  $C_5H_5N$  from pyridine sulfate obtained from coal tar. A. PAPINEAU-COUTURE

The recovery of pyridine and phenol from raw benzene. H. A. J. PIETERS and M. J. MANNENS. *Chem. Weekblad* 26, 286-90(1929).—The titration of pyridine in dil. solns. and with methyl orange as indicator gives very inaccurate results. (The error is less than 0.5% if dimethyl yellow and methylene blue are used as indicators (Kolthoff, *Massanalyse* II 66, 1928) and if the final concn. is not less than 0.1 g. per 100 cc. Phenol and pyridine can be recovered from raw benzene by washing prior to distn. The efficiency of the process depends on the initial concn. In one run, 16 tons of raw benzene yielded 34 kg. pyridine dissolved in dil.  $H_2SO_4$  at 150 g. per l. and 50 kg. phenol at 140 g. per l. The acid consumption decreased 30%, while the NaOH increased 50%, and the washing losses were decreased 35%. G. CALINGAERT

Manufacture of water gas from powdered coal. H. L. RAMSEY. *Ind. Chemist* 5, 156-9(1929).—Recent advances in the production and use of water gas and in the use of powd. coal are pointed out. The Howard "reverse air-blast-process" and the "pier" for the use of bituminous coal in the production of water gas are described briefly. The work and proposals of K. M. Balley, Clauss, R. H. Burditt, La Combustion Rationnelle Co., Max Klötzer, Trenkler, Ledebör and Jamotte, Haslam, Gwosdz, Interessen Gemeinschaft, H. W. Benner and Trent are discussed. E. G. R. ARDAGH

Technical processes for removing sulfur compounds from gases. HORST BRÜCKNER. *Gas u. Wasserfach* 72, 442-5(1929).—A critical review of the most important methods for removing S compds. from gas, with extensive references to patents and literature. R. W. RYAN

Locomotive firebox conditions: gas compositions and temperatures close to copper plates. T. M. HERBERT. *Proc. Inst. Mech. Eng. (London)* 1928, 985-1006.—Locomotive firebox gases were sampled through hollow stays in side sheets of the firebox. The heads of the stays were arranged so that the sample was taken next to the plate. Av. analyses of gases for various positions on the side plate and with heavy and light working of a freight locomotive were  $CO_2$  11.0-13.7%,  $O_2$  2.7-5.2% and CO 1.6-5.8%. Tests on a passenger locomotive running at 35-60 miles per hr. gave similar firebox gas analyses. The gases are not as a rule highly oxidizing, nor are they reducing except for short periods. The temps. attained at stayheads were detd. by drilling small holes in the head and inserting plugs of a series of fusible alloys having melting points at 220-380° by 10° steps. Tests were made on several types of locomotives working with good and bad boiler water as used in England and Scotland. The av. temps. were between 251 and 295° with a max. of 345°. The surface temps. rise during life and soiling of the firebox, while superimposed on this is periodic rise and fall of temps. due to washing of boilers. The temps. are affected by the amount of work the engine does. Narrow fireboxes show greater extremes of heat. A. W. HOLMES

The processes of Georges Claude for the separation of gas by liquefaction and the synthesis of ammonia. JEAN DELORME. *Proc. 2nd Intern. Conference Bituminous Coal* 2, 223-30(1928). E. H.

The gas and tar industries in France. JEAN BING. *Proc. 2nd Intern. Conference Bituminous Coal* 2, 766-88(1928). E. H.

Increasing the value of low-temperature carbonization tars. M. STÉMART. *Chimie & industrie Special No.*, 305-11(Feb., 1929).—Low-temp. carbonization tests on a lab. scale (25 kg.) with a Polish, non-agglutinating coal contg. 30.5% volatile gave a max. yield of primary tar (90-5 l. per ton) at a temp. of 375° in the tar vapors just above the coal (corresponding to 425-50° in the coal), with corresponding yields of 60-5 cu. m. of gas contg. 9-10 l. of "gasoline" boiling at ordinary temp. and 840-60 kg. of semi-coke. A Scotch coal contg. 34.6% volatile gave max. tar yield at the same temp., at

which there was obtained: tar 114 kg., gas 40.5 cu. m., semi-coke 778.5 kg. Comparative tests with very wet coal and the same having a normal  $H_2O$  content showed that partially dried coal gave a higher gas yield. A moderate general preheating of the coal does not affect the tar and gas yields, but permits of reducing the time of heating about 50%. Fractional distn. of tars obtained in lab. and semi-com. tests gave 25–30% of gasoline with initial b. p. of  $90^\circ$  of which 80–90% distills up to  $380^\circ$ . When the carbonization is not properly controlled, the yield of gasoline is reduced to about 15% and the amt. distg. below  $360^\circ$  to about 50%. At the present time, cracking of the tar (after distn. to remove the gasoline it contains) is considered the best treatment, as the degasolined tar can give up to 50% of gasoline on cracking, and the higher phenols are converted into lower phenols, for which a market is more readily found. The most satisfactory method of refining was hydrogenation by the Kling-Florentin process (treating at  $400\text{--}500^\circ$  with H at a pressure of up to 500 kg. per sq. cm. in the presence of catalyzers, followed by bleaching with  $SiO_2$  gel, the process being preferably applied directly to the degasolined tar). The Centrales Électriques des Flandres et du Brabant has installed a plant for the commercial application of these results, with a view to recovering by-products from the coal burned in the central power station; the cracking plant uses the Dubbs process and is designed to be able to treat heavy petroleum oils as well as the tar.

A. PAPINEAU-COUTURE

**The "E-phenols" of primary tar.** G. VAVON AND N. ZAHARIA. *Chimie & industrie Special No.*, 257–60 (Feb., 1929); cf. C. A. 23, 1247.—It is shown that all phenols are extractible by  $Et_2O$  from alk. soln., the "extn. coeff." varying within wide limits with the constitution of the phenol: it is increased by introduction of aliphatic radicals in the mol., the increase being greater the larger and more numerous the substituted radicals, and it is greater when substitution takes place in *o*-position than in *p*-position. The latter observation furnishes a method of distinguishing between isomeric *o*- and *p*-phenols. From a discussion of the results, Weindell's distinction between "*e*-phenols" and "*ne*-phenols" (C. A. 18, 1741) is considered to be without foundation. A. P.-C.

**Cracking in the distillation of coal tar.** F. J. POPHAM. *Ind. Chemist* 5, 179–80 (1929).—Distn. results obtained by quick and slow lab. distn. and works distn. with steam of a coke-oven tar indicate that the cracking was not particularly rapid, and is due to maintaining the tar at a high temp. for a prolonged period. The tar could be heated to  $400^\circ$  in the lab. with increasing yields of creosote without undue cracking and without the production of much free carbon provided the distn. was sufficiently rapid. In ordinary distn. 40% or more of the creosote is obtained by cracking. By making an alc. extn. and a  $CS_2$  extn. it was found that the largest % of creosote comes from the alc.-sol. portion and this is accompanied by the lowest free-C formation, indicating that cracking takes place in the heavier fractions. The time factor is more important than the temp. factor.

E. G. R. ARDAGH

**Hydrogenation of pitch.** G. HUGEL. *Chimie & industrie Special No.*, 128–33 (Feb., 1929); cf. C. A. 23, 2018.—A coke-oven coal-tar pitch, giving 43.8% of liquid products distg. at  $50\text{--}350^\circ$ , was berginized 10 hrs. at  $480^\circ$  under an initial pressure (cold) of 100 kg. per sq. cm. It absorbed 5.7% H and on distn. yielded:  $50\text{--}250^\circ$  16.5,  $250\text{--}300^\circ$  12.0,  $300\text{--}50^\circ$  16.0,  $350\text{--}400^\circ$  13.0, pitch 15.0, coke 27.0, loss 0.5%. The use of alkali hydrides as hydrogenation catalyzers is briefly discussed. According to Nellensteyn (C. A. 21, 3738) there are 3 components to asphalt: an oily phase, a lyophilic portion consisting of protective compds., and a lyophobic portion consisting of the C: when a small quantity of a reagent ( $NaH$ ,  $H_2SO_4$  and  $C_6H_6$  were used) is added to such a medium, the reagent is absorbed; but if a large amt. is added there is an irreversible flocculation due to the destruction of the micella. By adding a small quantity of  $C_6H_6$ , flocculation of the pitch was avoided and yields of up to 80% (85% when it is considered that the pitch used contained about 5% of C insol. in all solvents) of liquid products were obtained. Hydrogenation at very low temp. (e. g.,  $250^\circ$ ) of coke-oven pitch gave no oil, but a soft pitch, which could even have the consistency of a viscous liquid. The successive changes of pitch as a function of the H absorbed being followed under suitable conditions, it was found that most of the latter was absorbed without any apparent change in the colloidal structure of the pitch, which gradually becomes softer until it is converted into a thick, viscous liquid, insol. in benzine, and which may be termed "hydro-pitch." The conversion of "hydro-pitch" into oils with destruction of its colloidal structure requires a relatively small absorption of H. Hydrogenation of indene gives a very stable colloidal hydrocarbon of the same nature as the cycloparaffins; if this hexahydropolylindene is subjected to moderate cracking, it splits into smaller units, the free valences being satd. with H. The 1st change (conversion into hexahydropolylindene) is considered to be similar to the conversion of pitch to "hydro-pitch" and

is accompanied by a large absorption of H, while the cracking of the hexahydropolymers requires but a small absorption of H and is similar to the production of oils from "hydro-pitch." The pitch oils contain practically no  $C_6H_6$ . The 1st portions start coming off at about 200°, indicating the presence of tetralin, and hence of the naphthalene nucleus. Most of the pitch oil constituents must contain very highly condensed nuclei as they distil at ordinary pressure without decompn. at temps. above 500° and even 600°. The base of these substances is certainly formed of polyaromatic hydrocarbons, such as chrysene, picene, etc., because they give well-crystd. hydrocarbons on dehydrogenation. In the pitch these highly condensed nuclei are connected by unsatd. side chains (as in polystyrene) or by unsatd. hydroaromatic or cycloparaffin nuclei. This hypothesis does not take into account the O, N and S; but as these are eliminated quite rapidly in the early stages of hydrogenation in the presence of NaH without any change in the colloidal structure of the pitch, it is not considered that combinations with these elements play the most important part in the structure of pitch.

A. PAPINEAU-COUTURE

**An economic test of low-temperature coking.** R. S. McBRIDE. *Chem. Met. Eng.* 36, 288-91(1929); cf. *C. A.* 22, 3760.—A low-temp. carbonization plant and its operation are described.

A. WHITE

**Coke-oven operation.** K. S. ZAREMBO. *J. Chem. Ind. (Moscow)* 6, 254-8(1929).—In the coke ovens of old construction, which are in operation in the Don basin, the hydraulics which take the place of modern gas collectors are sprayed with tar, and the resultant fuel gas is contaminated with very large quantities of naphthalene originating in the decompn. of the tar; as a result, gas conduits, scrubbers, condensers, etc., become plugged and considerable other trouble is experienced. Expts. show that spraying should best be effected continuously and at a max. of intensity and that it is best to spray the hydraulics with weak  $NH_3$  soln. instead of with tar; tar may be introduced only once in 24 hrs. while cleaning the hydraulics from foots which it helps to dissolve and remove. At any rate, the gas obtained is defective, since it contains too much N and Cl and attacks the metal of the installation.

BERNARD NELSON

**Recovery of coke-oven by-products.** J. O. *La Nature* 2808, 406-13(1929).—A description of  $NH_3$  recovery, tar treatment and utilization of gases.

P. THOMASSET

**Heat required for the coking process.** ERNST TERRES. *Proc. 2nd Intern. Conference Bituminous Coal* 2, 657-84(1928); *Gas u. Wasserfach* 72, 361-9(1929).—Methods for detg. the heat of coking, the heat of decompn. of coal and also the (heat) cond. of coal and coke are given and discussed. They are also applied to the detn. of the length of the coking period and used to explain the differences in the coking properties of various German coals.

R. W. RYAN

**Investigations of the reactivity of chamber coke towards a mixture of nitric and sulfuric acids.** R. KATTWINKEL. *Glückauf* 65, 634-8(1929).—The reducing action of various types of coke (used in the Gay-Lussac tower of the  $H_2SO_4$ -Pb-chamber process) on a mixt. of  $HNO_3$  and  $H_2SO_4$  was detd. by heating 10 g. of coke with a mixt. of 100 g. 36° B $\acute{e}$   $HNO_3$  and 1000 cc. 60° B $\acute{e}$   $H_2SO_4$  for 2 hrs. at const. temp., 70°. The mixt. was filtered over coke and the filtrate titrated with 0.5 N  $KMnO_4$ . Eight successive detns. were made with the same coke and fresh acid mixts. The results varied with different cokes even when they originated from the same coal. The reactivity depends on the chem. constitution of the coke. Blast-furnace coke is more reactive than foundry coke because (1) the C of the former is amorphous and active while the graphitic-cryst. C of the latter prevents the liberation and gasification of the more reactive C; (2) the greater porosity and lesser hardness of the former create a larger surface of effective C mols. Increased loss of ash during the test is accompanied by greater reactivity due to the increased available C surface.

J. B. SHOHAN

**Specific heat of gases in combustion technic (LUNDBERG) 2. Use of pulverized coal as a fuel for periodic kilns (WATSON) 19. Removing S compounds from gases (Fr. pat. 652,243) 13. Gasoline from solid bituminous material (U. S. pat. 1,714,963) 22. Separating oil from gases (Fr. pat. 651,857) 13. Separating hydrocarbons, etc., by fractional solution (Brit. pat. 300,266) 22. Apparatus for mixing or blending gases (U. S. pat. 1,714,284) 1. Apparatus for scrubbing gas (U. S. pat. 1,715,252-3) 1.**

**Fuel briquets.** CHEMISCHE-TECHNISCHE GES. Brit. 300,195, Nov. 8, 1927. In forming briquets from fuels of different coking properties, the coking fuel is heated to or below the softening temp. (suitably about 300°) and the non-coking fuel to a higher temp. (suitably about 600°) and the fuels are then mixed and briquetted. The mixing and briquetting may be effected in a continuous operation.

**Governing combustion of powdered fuel in suspension.** ALFRED COTTON. U. S. 1,713,817, May 21. The fuel is carried in suspension in a mixt. of air and combustion gases, the relative proportions of which are regulated so as to control the rate of combustion.

**Regulating combustion in boiler furnaces by varying the supply of oxygen.** SIEMENS-SCHUCKERTWERKE A.-G. Brit. 299,885, Nov. 4, 1927. O is added to the air and its supply is increased with increase in the load. Air may be supplied in unchanged quantity or its quantity may be varied inversely with that of the O.

**Light oils from solid or liquid hydrocarbons.** P. GIRARD, F. PETIT and A. CHARBONNEAU. Brit. 299,861, Nov. 3, 1927. In a process such as that described in Brit. 290,606 (C. A. 23, 959), in which solid fuel is distd. in the presence of an oxidizing agent to obtain light hydrocarbons, a substance which gives off nascent O on heating such as  $\text{KMnO}_4$ ,  $\text{MnO}_2$  or  $\text{K}_2\text{Cr}_2\text{O}_7$  is used. The process may be applied to materials such as resins, pitch, bitumens, waxes, tars, asphalts and products obtained by the treatment of solid fuels with solvents such as petroleum or coal oils. Gas is evolved and about 10% of coke is formed. The reaction may be assisted by ionizing the vapors by high-frequency discharges.

**Setting for vertical retorts, recuperator chambers, etc.** LOW TEMPERATURE CARBONIZATION, LTD., and C. H. PARKER. Brit. 299,795, April 27, 1927. Structural features.

**Carbonization retorts.** CHARLES TURNER. Fr. 651,729, Mar. 24, 1928.

**Carbonization of fuel.** I. G. FARBENIND. A.-G. Fr. 652,405, April 10, 1928. In the carbonization of fuel at low temp. hot inert gas or vapors are blown through a layer of the fuel in amt. sufficient to keep the fuel in agitation.

**Carbonizing coal.** IRVING F. LAUCKS (to Old Ben Coal Corp.). U. S. 1,713,840, May 21. Coal which becomes plastic on sufficient heating is passed through a cylindrical retort by the action of a screw and is simultaneously heated in such a regulated manner that at the zone where the plastic coal commences to set, the screw is hotter than the retort, so as to conclude the setting process at the rotor while the plastic coal adheres to the retort. An app. is described.

**Carbonizing and gasifying powdered coal.** W. H. TRENT (to Trent Process Corp.). Brit. 299,792, Oct. 25, 1926. Waste combustion gases from a furnace are passed into contact with a continuously moving body of the coal, and the coke powder thus produced is transferred while hot to a gas producer so as to generate producer gas for use in the furnace. The plant includes a boiler furnace.

**Heating pulverized coal while in a pneumatic conveyor leading to a furnace.** W. H. TRENT (to Trent Process Corp.). Brit. 299,718, Oct. 25, 1926. The conduit and storage receptacle for the coal are heated so that the coal itself may be brought to a temp. of  $200^\circ$  at which gas is continuously evolved and serves to accelerate the flow of the coal.

**Distillation of coal.** LOW TEMPERATURE CARBONIZATION, LTD. Fr. 652,540, Mar. 23, 1928. In low-temp. distn. the substance to be distd. is introduced in containers which are caused to pass through a retort by rolling on an inclined path from the charging point to the outlet. Means are provided for closing the retort at both ends. Cf C. A. 23, 3332.

**Hydrogenation of coal, tar, mineral oils, etc.** I. G. FARBENIND. A.-G. Fr. 651,891, Mar. 28, 1928. Valuable hydrocarbons of low b. p. are obtained by the action of H on coal, tar, mineral oils and their distn. products at temps. above  $300^\circ$ , and preferably under pressure, in the presence of oxides of elements of the 3rd to the 7th group of the periodic system, pptd. in small proportions on metals or alloys. Examples are given of the production of benzines, the main portion of which boils below  $200^\circ$ , from mineral oil and lignite-tar oil using Al coated with U nitrate or boric acid or  $\text{NH}_4$  vanadate, or Zn wool evapd. with a suspension of the blue oxide of Mo, at about  $450^\circ$  and 200 atm.

**Briquets from coal, etc.** P. J. SPENGLER and J. P. SPENGLER. Brit. 299,859, Nov. 4, 1927. Briquets are formed from coal or a mixt. of coal and coke with a binder such as tar by repeated pressing operations at gradually increasing pressures.

**Apparatus for removing water from peat.** L. L. GINTER. Russ. 5603, Sept. 15, 1924. Mechanical features are specified.

**Montan wax.** I. G. FARBENIND. A.-G. Fr. 651,869, Mar. 29, 1928. Montan wax is treated with oxidizing agents in acid soln. under such conditions that a yellow to white product is obtained similar to carnauba wax, but much more easily sapond. and emulsified than the latter. Examples are given.

**Gas.** WALTER SCHWEDER. Fr. 652,277, April 5, 1928. See Brit. 288,336 (C. A. 23, 693).

**Purifying gas.** H. KOPPERS A.-G. (to C. J. Hansen). Brit. 299,765, Oct. 31,

1927. In effecting removal of  $\text{NH}_3$  and  $\text{H}_2\text{S}$  from gas by washing with liquor contg. Fe and oxy compds. of S, as described in Brit. 299,302 (C. A. 23, 3332), a liquor is used which contains a metallic salt which reacts with  $\text{H}_2\text{S}$ . A soln. of Fe thiosulfate may be used and the spent liquor may be regenerated with  $\text{SO}_2$ ; salts of Zn and Mn also may be used. Various other details are described.

**Gas producer.** BERNITZ FURNACE APPLIANCE CO. Brit. 299,627, Dec. 2, 1927. The fuel bed is enclosed in a casing formed by hollow bricks and cooled by circulation of gases which subsequently pass mainly into the lower portion of the charge. Various structural details of the producer are described.

**Gas producer for mixed gases.** ULRIC DE TOYTOT. Fr. 652,152, July 27, 1927.

**Plant for water-gas manufacture.** MAX W. ERDMANN. U. S. 1,715,064, May 28. Flat flaring nozzles placed helically about a carburetor inject oil vapors into the carburetor in fan-like streams from different directions.

**Production of water gas from natural gas.** EDWARD H. BOOMER (to Governors of the University of Alberta). Can. 289,830, May 21, 1929. A mixt. of 1 g. atom of O to each g. atom of C in the natural gas is passed at a pressure of 1 to 2 atm. and at a temp. exceeding  $975^\circ$  over suitable catalysts; a max. yield, from a commercial standpoint, of water gas is obtained.

**Coke-oven gas.** GESELLSCHAFT FÜR LINDE'S EISMASCHINEN A.-G. Fr. 652,326, Apr. 6, 1928. In the decompn. of coke-oven gas by partial liquefaction triple-bond compds. are eliminated before liquefaction by washing with suitable solvents or by treatment with HCl or Cl in the presence of catalysts to oxidize or hydrogenate them. Parts of the app. made of Cu or its alloys coming in contact with the gas are covered with Sn or Pb to avoid formation of compds. of Cu with  $\text{C}_2\text{H}_2$ . Other gases which tend to cause explosions such as  $\text{NH}_3$ , oxides of N and water vapor are also eliminated. Cf. C. A. 23, 1740.

**Preventing corrosion in wet gas meters.** J. A. FLETCHER and C. R. NORMAN. Brit. 300,096, May 16, 1928. An oil emulsion such as may be formed from cottonseed oil, mineral oil, fish oil and KOH soln. is used as the liquid in which the drums or bells work. Cf. C. A. 22, 3037.

**Storing acetylene.** M. ROHRSCHEIDER. Brit. 299,681, April 24, 1928. An absorbent filling for use in receptacles for storing  $\text{C}_2\text{H}_2$  comprises finely divided leather, freed from acids, water and acetone-sol. constituents, and which may be mixed with pulverulent or granular heat-resistant materials such as pumice or kieselguhr. If grease-free leather such as chrome leather waste is used, extn. with acetone (otherwise usually employed) may be omitted.

**Tar distillation.** THE BARRETT CO. Fr. 652,109, April 3, 1928. Tar is distd. by spraying it into hot coal gases as they pass from the retorts to a collector main, and the resulting gases and vapors while hot are purified from suspended particles by subjection to elec. discharges and finally cooling to condense the oils. Cf. C. A. 23, 3075.

**Distilling tar acids.** J. A. SHAW (to Koppers Co.). Brit. 299,837, Nov. 2, 1927. Tar acids such as phenol or cresol are removed from liquids such as gas liquor obtained in the carbonization of coal, etc., by maintaining the liquid at a temp. just below its b. p. and blowing an inert gas such as air through it. Tar acids are removed from the gas (suitably by NaOH) and the gas is recirculated. An arrangement of app. is described.

**Plant for utilizing heat from quenching coke for generating steam under pressure.** OSWALD HELLER. U. S. 1,714,168, May 21.

**Coke oven.** JOSEPH VAN ACKEREN (to Koppers Co.). U. S. 1,714,933-4, May 28.

**Coking pitch.** HEINRICH KOPPERS (to Koppers Development Corp.). U. S. 1,715,240, May 28. A body of pitch is gradually accumulated and simultaneously coked as the depth of the coking mass is gradually increased by addn. of liquid pitch to the top surface of the mass. An app. is described.

## 22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

W. F. FARAGHER

**Petroleum refinery statistics 1927.** G. R. HOPKINS. Bur. Mines, *Bull.* 297, 93 pp.(1929). E. H.

**The petroleum industry in 1928.** R. KISSLING. *Chem.-Ztg.* 53, No. 43, *Fort-schrittsber.*, 61-8(1929). E. H.

**Sulfur compounds in pressure-cracked naphtha and cracked naphtha sludge.** D. S. MCKIRTRICK. *Ind. Eng. Chem.* 21, 585-92 (1929).—From a naphtha derived from the cracking of a fuel oil from Midway crude oil (California), thiophene and its 2-Me, 3-Me, 2,3-dimethyl, 3,4-dimethyl, 2-Et and 3-Et derivs. were isolated in the form of their mercurichloro compds. These compds. were obtained from that portion of the naphtha which boiled below 160° (cf. C. A. 22, 2459). The acid sludge obtained from the sulfuric-acid treatment of the naphtha yielded two compds. of unknown structure. They were apparently absent in the untreated oil. They contain 8 and 11 carbon atoms, b. 162-8° and 229-30°, and have  $n$  1.468 and 1.486, resp. The d. of the first compd. is 0.900. Their chem. and phys. properties indicate that they are cyclic sulfides. The lower-boiling substance forms two compds. with  $\text{HgCl}_2$ ,  $(\text{C}_8\text{H}_{13}\text{S})_2 \cdot 7\text{HgCl}_2$ , m. 147.5-8.0°, and  $\text{C}_8\text{H}_{13}\text{S} \cdot 3\text{HgCl}_2$ , m. 130-0.5°. (The high mol. wts. do not permit the differentiation between straight-chain and cyclic compds.). Under the same conditions of prepn.,  $\text{Bu}_3\text{S}$  and iso- $\text{Bu}_3\text{S}$  form  $\text{Bu}_3\text{S} \cdot 2\text{HgCl}_2$ , m. 110-0.5°, and (iso- $\text{Bu}_3\text{S}) \cdot 5\text{HgCl}_2$ , m. 131.5-2.0°. The following compds. were also prepd.:  $\text{Et}_3\text{S} \cdot 3\text{HgCl}_2$ , m. 131.5-2.0°;  $\text{Pr}_2\text{S} \cdot 2\text{HgCl}_2$ , m. 126.5-7.5°; and allyl sulfide tetrabromide (di-2,3-dibromopropyl sulfide), m. 94-5.5°.

I. M. LEVINE

**Study of the double bonds in petrolatums.** R. POGGI. *Giorn. chim. ind. applicata* 10, 601-5 (1928).—The method of Rosenmund, which depends on the action of  $\text{C}_6\text{H}_5\text{N} \cdot \text{H}_2\text{SO}_4 \cdot \text{Br}_2$  as the brominating agent, was found to be much more reliable for the detn. of unsatn. than the Hanus method. The unsatn. of various commercial petrolatums was studied because this is important in detg. the value as a stabilizer in storing smokeless powder. The colorimetric method of Angeli (C. A. 4, 2457) for unsatn. was compared with the above methods. In this method the vaseline sample, about 1.5 g., is dissolved in 9 cc.  $\text{CHCl}_3$ , and 50-80 mg.  $\text{C}_6\text{H}_5\text{NO}$  added through a stoppered buret into a closed air-tight vessel, and placed in the dark. As the reaction proceeds the color changes from a blue-green eventually to yellow, depending on the extent of the reaction. Only slightly colored vaselines can be tested. A vaseline showing only 0.7 mg.  $\text{Br}_2$  addition (Rosenmund) remained blue-green 17 days; one showing 8.1 mg.  $\text{Br}_2$  addn. changed to yellow-green in 4 days; one showing 95.0 mg.  $\text{Br}_2$  addn. changed to yellow in 1 day. A. W. C.

**Some properties of fuller's earth and acid-treated earths as oil-refining adsorbents.** C. W. DAVIS AND L. R. MESSER. *Am. Inst. Mining Met. Eng. Tech. Pub. No. 207*, 18 pp. (1929).—"Acid-treated" earths include those products from the partial decompn. of mineral matter by acid which are equal to or more efficient than an untreated fuller's earth for bleaching mineral oil by the "contact" process. This process consists in heating and agitating the oil with finely divided adsorbent that is subsequently removed by filtration. The results of exptl. work with 17 earths are given. Most fuller's-earth deposits are sedimentary; some deposits in Arkansas and in Massachusetts are exceptions. Slides show California earths, which, when acid-treated, produce com. adsorbents that may be divided into 2 classes: those which show the texture of volcanic ash and those too fine-grained to exhibit a characteristic texture. The chem. compns. of fuller's earths and of earths from which oil-bleaching adsorbents may be prepd. are widely divergent, but a high silica-alumina ratio is characteristic of them. Identification tests on fuller's earth are applicable only to materials from certain districts. Swelling in  $\text{H}_2\text{O}$  is apparently peculiar to earths that become good adsorbents by acid treatment, but earths that swell do not always become good oil bleachers. The concn. of  $\text{H}_2\text{SO}_4$  in the water-acid soln. that produced the best adsorbents ranged from 15 to 20% by wt. Higher concns. are detrimental. Analyses of several adsorbents and clays are tabulated and several graphs shown.

W. H. BOYNTON

**Progress in the field of mineral oils.** MAX NAPHTALI. *Z. angew. Chem.* 42, 508-18 (1929).

E. H.

**Artificial aging of mineral oils. II.** F. EVERS AND R. SCHMIDT. *Wiss. Veröffentlich. Siemens-Konzern* 7, 343-71 (1928).—Lab. aging tests of insulating oils are made by heating the oil at 120° in a closed tube filled with  $\text{O}_2$ , after previously mixing the oil with silica gel impregnated with a catalyst. Sixty g. of gel is stirred with 44.48 g. of  $\text{FeSO}_4$  crystals dissolved in  $\text{H}_2\text{O}$  and, after oxidation has taken place, the mass is soaked in 100 cc. of  $\text{H}_2\text{O}$  contg. 14.13 g. of  $\text{NH}_4$  heptamolybdate, dried and heated at 410° until  $\text{NH}_3$  and  $\text{H}_2\text{SO}_4$  are expelled. This amt. is sufficient for 15 g. of oil. American and Russian oils give curves of the form  $y = c \log x + k$ , when the  $\text{O}_2$  absorption is plotted against the time;  $c$  and  $k$  vary with temp., compn., phys. character and proportion of catalyst used. Oxidation is apparently confined to the constituents with a double linking, and the presence of unsatd. fatty acids appears to have no influence on the rate of oxidation.

B. C. A.

**The Estonian combustible shales.** J. GELLER. *Arch. Warmewirt.* 9, 345-9

(1928).—The location, seams, winning, compn. and uses of these shales are described. Of 300,000 tons produced yearly, railroads consume nearly half, and cement works, carbonization plants and other industries most of the rest.

ERNEST W. THIELE

**Goudron number of oils.** LESZEK HOZER. *Przemysł Chem.* 13, 12-16(1929).—A soln. of 60 cc. of the oil in 100 cc. of light benzine is shaken for 3 mins. with 10 cc. of concd.  $H_2SO_4$  in a graduated cylinder. After standing for 1 hr. the increase in vol. of the acid is read. This increase expressed as a percentage of the oil used is its goudron no. (tar no.). A few drops of water may be added to facilitate the reading of vol. if the mixt. is too dark (cf. Maim, *Chem. Revue* 7, (1905)). This value, which is taken to represent very roughly the amt. of unsatd. bonds, is widely adopted in Russia and to some extent also in Poland in the most general classification of petroleum products. It is very misleading, however, for the characterization of oils because it cannot give consistent results, and is not suitable as an analytical const. for evaluating and comparing oils. Only the curve representing the effect of concn. of  $H_2SO_4$  on the goudron no. can serve for characterizing oils.

A. C. ZACHLIN

**Steam-turbine oils.** H. STÄGER AND J. P. BOHNENBLUST. *Arch. Wärmewirt.* 8, 349-56(1927); 9, 59-63(1928).—Steam-turbine oils were kept at  $112^\circ$  in open containers for 1000 hrs., and a portion was treated with fuller's earth. The original oils, the oxidized oils and the filtered oxidized oils were studied, as well as some oils which had been used in turbines. The film-forming properties were detd. by measuring the angle of contact with steel, cast iron, bronzes and white metals by the method of Dallwitz-Wegener (*C. A.* 20, 3076). The first 2 show the highest (poorest) contact angle. The oxidized oils are better than the original, but when filtered, the angle of contact is little better than in the original state. The viscosity and compn. of the oils have no connection with the contact angle. The surface tension against water and solns. was measured by the drop-wt. method. Oxidation reduces this value greatly, especially with caustic and soda solns.; NaCl and  $H_2SO_4$  solns. behave nearly like water. Emulsibility was detd. by admitting steam to an oil-water mixt. and studying the sepn. The fresh oils all sepd. well; in general, the oxidized oils emulsified badly, either with water or caustic or with both. In all tests, used oils behaved like the oxidized oils; sometimes they were more oxidized than the exptl. oils.

ERNEST W. THIELE

**The testing of steam-turbine oils.** H. STÄGER. *Arch. Wärmewirt.* 9, 383-4(1928).—A review of Swiss work, concluding with the specifications of the Brown Boveri Co. for these oils. Details of the aging test are given.

ERNEST W. THIELE

**Investigations on steam-turbine oils.** H. STÄGER. *Congrès intern. essai des matériaux* 1927, II, 457-69(publ. in 1928).—Tests are usually made on oils as delivered but their quality as lubricants may alter greatly with use; hence tests are necessary to det. the character of the changes. Stäger assumes that the smaller the angle of contact of oil with metal, the greater the "wettability" and the greater the adhesion; but there are considerable differences which depend upon the compn. of the metals in use, which are of three principal kinds: (1) steel and cast iron; (2) brass and bronze; and (3) white metal. For a bearing metal, a well-marked heterogeneity is necessary, and in the process of "running in," a fine relief surface is produced, which assists the spreading of the lubricant. S. studied fourteen oils after several thousand hrs. of use and also after 1000 hrs. of heating in air at  $112^\circ$ . The two sets are quite similar. There is a marked change in the adhesion, which is due to the production of polar groups in the mol. and not to increase in viscosity. The adhesion is weakest for steel, better for bronze, and best for white metal; it is not impaired when Sn is replaced by Pb. By treating the aged oils with fuller's earth, which removed the polar compds., the wettability was decreased very greatly. Some substances of high wettability are not acidic. Foam and emulsion formation is not detd. by viscosity and surface tension, but rather by substances on the interfaces, which are foam-formers. The max. foam production occurs when the mols. of the dispersion medium and of the foam former are in equal numbers. Neutral salts are not likely to injure oils but alkalies are.

EUGENE C. BINGHAM

**Adaptation of the stability test to plant and field control (asphalt).** P. HUBBARD AND F. C. FIELD. *Asphalt Assoc. Circ.* No. 49, 51-5(1929).

E. I. S.

**"Braunkohlenbenzin" or "Braunkohlenbenzol?"** MALLISON. *Z. angew. Chem.* 42, 427-9(1929).—Benzine has no precise meaning, while benzene (or benzol) has. The volatile liquid obtained partly from the gases from lignite distn., partly from the light oil from lignite tar, and sold as a motor fuel, has been called by both names in the title as well as by fanciful terms. In spite of its antiknock properties, it should be called "-benzin" and not "-benzol" because it certainly contains far less than 50% of aromatic hydrocarbons.

AUSTIN M. PATTERSON

**A study of auto-ignition temperatures. III. (a) Mixtures of pure substances;**

(b) **gasolines.** HENRY J. MASSON AND WILLIAM F. HAMILTON. *Ind. Eng. Chem.* 21, 544-9(1929); cf. *C. A.* 22, 3567.—Measurements were made of the auto-ignition temps. of a no. of mixts. having a wide range of characteristics. Curves are given showing the relationship between compn. and auto-ignition temp. PbEt<sub>4</sub> raises or lowers the auto-ignition temp. toward the optimum. A working hypothesis is advanced for correlating auto-ignition temps. and knock.

FRANK V. JOHNSON, JR.

**Study of the phenomena of the combustion of gas mixtures by recording the pressures.** M. AUBERT AND A. PIGNOT. *Chimie & industrie Special No.*, 231-3(Feb., 1929); cf. *A., P.*, and Villey, *C. A.* 22, 863.—The app. used, consisting essentially of a combustion cylinder, a manometer and a recording device, is described. The results of expts. carried out on cyclohexene agree with those of the previously reported expts. and show that: (1) when the mixt. is enriched in hydrocarbon, the curve representing the variations of max. pressure as a function of the compn. of the mixt. has a very much flattened max.; (2) for each hydrocarbon in admixt. with air, there are limiting compns. of the mixt. between which combustion is particularly active: the time clapsing between the beginning of the increase in pressure and the max. elongation of the manograph is very short; on the other hand, the retardation of inflammation increases fairly regularly with the proportion of combustible gas.

A. PAFINEAU-COUTURE

**Contribution to the study of the pressures of combustion.** M. AUBERT AND A. PIGNOT. *Ann. combustibles liquides* 3, 591-611(1928).—As the volumetric compression ratio is increased from 3.87 to 8.28, the max. adiabatic auto-ignition pressure of cyclohexane:air mixts. (1:12 by wt.) rises, the duration of inflammation increases (0.0025 to 0.0036 sec.), the ratio of the max. ignition pressure to initial pressure decreases (5.3 to 2.83 kg./sq. cm.), and the lag of inflammation decreases (0.054 to 0.0021 sec.). At the volumetric compression ratio 8.28, the lag and duration of inflammation increase (0.0021 to 0.023 sec. and 0.0036 to 0.0053 sec., resp.) as the temp. is decreased from 100° to 63°. With C<sub>6</sub>H<sub>14</sub>, cyclohexane and C<sub>6</sub>H<sub>6</sub> the auto-ignition pressures reach maxima of about 69, 63 and 56 kg./sq. cm., resp., for the respective air-fuel ratios 9.24:1, 6.33:1 and 6.28:1. With the air:fuel ratios 16.1:1 for C<sub>6</sub>H<sub>14</sub>, 15.6:1 for cyclohexane and 14:1 for C<sub>6</sub>H<sub>6</sub> the corresponding durations of inflammation are 0.0033, 0.0032 and 0.0058 sec., resp. Perhaps these differences in inflammation duration may account for the antiknock properties of C<sub>6</sub>H<sub>6</sub>. The effects of antiknock compds. on the duration of the combustion process are given (cf. *C. A.* 22, 2832).

R. E. SCHAAD

**The ultramicroscopy of asphalt and related products.** F. J. NELLENSTEIJN AND J. P. KUIPERS. *Kolloid-Z.* 47, 155 60(1929); cf. *C. A.* 22, 2266.—Further study has been made on asphalts and related products, which confirm previous work. Artificial asphalt from distn. residues of Mexican gasoline, an oxidized portion from these residues, and coal tar were studied. Solvents were C<sub>6</sub>H<sub>6</sub>, CS<sub>2</sub>, PhNO<sub>2</sub>, toluene, nitrotoluene, xylene, nitranisole, furfural and quinoline. In nearly all cases ultramicroscopic particles were easily observed. Best results for artificial asphalt were obtained with CS<sub>2</sub>, but if the surface tension is greater than 24 dynes/cm. at 25° and if asphalt and medium are miscible, the particles are plainly visible. At great diln. natural asphalt gives better ultramicroscopic results than artificial, although addn. of fine inorg. powders to artificial asphalt makes the samples comparable to coal tar. Lampblack with asphalt in soln. (in nitrobenzene, aniline, etc.) gives a good microscopic picture as well as ultramicroscopic.

RAYMOND H. LAMBERT

**Some aspects of hardwood distillation and its products.** M. SCHOFIELD. *Ind. Chemist* 5, 141-6(1929).—Much interesting information on the conditions surrounding the industry and on the various operations involved. Possible new processes and outlets for the products are discussed. A brief review of some of the research work that has been carried out on hardwood distn. and on the activation of the charcoal produced is given. Twelve photographs are included.

E. G. R. ARDAGH

**Pyrogenous decomposition of wood tar in the presence of hydrogen and under pressure.** V. N. IPAT'EV AND A. D. PETROV. *Akad. Wiss. Leningrad. Ber.* 62B, 401-7(1929).—Earlier investigation of the pyrogenetic decompn. in the presence of catalysts (Al<sub>2</sub>O<sub>3</sub>, Fe<sub>2</sub>O<sub>3</sub>) of a series of individual compds., which are constituents of wood tar, justified the assumption that the tar, heated with H<sub>2</sub> under pressure even at the relatively low temp. of 440-80°, would give considerable amounts of benzene and aromatic hydrocarbons as the result partly of cracking and partly of the reduction of unsatd. and O-contg. compds. The object of the present work was to study the influence of the conditions on these reactions and to compare the advantages, as regards the formation of the more valuable low-boiling products, of heating with H<sub>2</sub> or of distg. with H<sub>3</sub>PO<sub>4</sub> according to Melamid and Grützinger. Wood tar contains chiefly (1) alcs. (iso-Am, iso-Bu), (2) ketones of the Me<sub>2</sub>CO series and cyclic (satd. and unsatd.) ketones, (3)

various phenols and their mono- and polyethers, and (4) acids (palmitic, abietic, etc.). Alcs. have been shown to be dehydrated to  $C_2H_4$  hydrocarbons, which then condense to satd. (hexane, heptane), unsatd. (amylene, hexylene), and polymethylene hydrocarbons. In the presence of  $H_2$  there must also be at least a partial conversion into hydrocarbons of the paraffin series. Ketones with open chains are reduced to the corresponding hydrocarbons, and cyclic ketones in the presence of  $H_2$  react in the same way, as shown with cyclohexanone which, when heated for 24 hrs. at  $420-40^\circ$  with  $Al_2O_3 + Fe_2O_3$  and  $H_2$  under pressure, gives cyclohexane in good yield. Unsatd. cyclic ketones in the presence of  $H_2$  also give phenols besides hydrocarbons; on short heating, the only difference, as compared with heating without  $H_2$ , is that the total yield of liquid products is increased, whereas longer heating results in a decreased yield of phenols because of reduction (homoisophorone heated 2 hrs. at  $460-80^\circ$  with  $H_2$  gave 40% of phenols). This reduction of the phenols (uni- and bivalent) and their ethers (*o*- $C_6H_4(OEt)_2$ ) heated for 4 hrs. at  $430^\circ$  under  $H_2$  that gave 50% of liquid products (chiefly  $PhOH$  and  $C_6H_6$ ) is a distinct advantage over the  $H_3PO_4$  distn. method, in which the univalent phenols remain unchanged and the bivalent phenols are completely decomposed. The acids with  $Al_2O_3$  at  $440-60^\circ$  under  $H_2$  are easily decomposed, yielding chiefly very low-boiling hydrocarbons almost completely insol. in  $H_2SO_4$ . The high-boiling fractions of the wood oil, especially the pitch, may contain, as shown by Benson, decompn. products of abietic acid (retene, chrysene, picene); these homologs of phenanthrene undoubtedly decompose in the same way as phenanthrene itself; in fact,  $C_{10}H_8$  and alkynaphthalenes were identified in the products of the pyrolysis of wood tar (in the absence of  $H_2$  at atm pressure,  $C_{10}H_8$  is formed only at temps. of bright redness). The products of pyrolysis lack the peculiar unpleasant odor of wood tar; the high-boiling fractions dissolve in part in  $H_2SO_4$  but do not darken on standing and can be used as lubricants and for other purposes. Both Kahlebaum's wood tar and a product richer in pitch from the "Veskolies" Trust were investigated. The results showed that on heating with  $H_2$  under pressure the total yield of liquid products is larger than on distg. with  $H_3PO_4$ ; the % of hydrocarbons and low-boiling fractions is higher; and the % of unsatd. compds. is materially smaller than in cracking without  $H_2$ . The conditions for obtaining the largest possible yield of liquid products are a temp. of  $440-60^\circ$  and an excess of  $H_2$  in the presence of catalysts. C. A. R.

**Motor fuels and other products from the cracking of wood tars.** JACQUE C. MORRELL AND GUSTAV EGLOFF. *Ind. Eng. Chem.* 21, 537-42 (1929).—The possibilities of the utilization of waste-wood products, particularly tars, from the destructive distn. of wood, by conversion into motor fuels and other products by the cracking process are shown by means of data obtained by cracking three types of wood tar. These data indicate that, in general, the products obtained from pine tar are most suitable for solvents and paint thinners. Hardwood tar may be utilized for the manuf. of low-boiling tar acids and phenols; Douglas-fir tar produces a highly antiknock motor fuel.

O. A. NELSON

**Present status of our knowledge of the composition of spirits of turpentine.** (MLLE.) MARCELLE BARRAUD. *Bull. inst. pin* 1929, 93-7.—A brief review of the compn. of spirits of turpentine obtained from different species of trees, with bibliography of 23 references.

A. PAPINEAU-COUTURE

**A technical study of the distillation of turpentine from Spanish pine.** MARIANO T. LACRUE. *Bull. inst. pin* 1929, 2-10.—The effects of varying quantities and temps. in the steam distn. of turpentine to obtain rosin and oil of turpentine are studied by means of graphs and tables. The conditions that diminish the yield of oil, given in the order of decreasing importance are: (1) the use of quantities of water smaller than those of the oil to be obtained; (2) the use of low temps., especially low final temps.; and (3) the working of large quantities of crude turpentine. MERRILL W. SEYMOUR

**Effect of cathode rays on hydrocarbon oils (SCHOEFFLE, CONNELL) 3.** Increasing the value of low-temperature carbonization tars (STÉMART) 21. Hydrogenation of pitch (Hugel) 21. Filter and gravity separator for oil and water, etc. (Brit. pat. 299,648) 1. Device for separating oil, water and air (U. S. pat. 1,714,825) 1. Scrubber for preventing loss of gasoline from storage tanks (U. S. pat. 1,715,112) 1. Light oils from solid or liquid hydrocarbons (Brit. pat. 299,861) 21. Hydrogenation of coal, tar, mineral oils, etc. (Fr. pat. 651,891) 21.

**Composition for purifying and clarifying crude petroleum oils.** DONALD E. WOODS and EARL J. NEELE (to Oil-O-Treat Co.). U.S. 1,715,217, May 28. A mixt. suitable

for treating Texas crude oil is formed of a heavy petroleum fraction such as gas oil about 68,  $H_2SO_4$  about 10, a fatty oil such as "redoil" about 14 and crude phenol about 8%.

**Distilling heavy petroleum distillates and residues to produce gasoline.** ALBERT E. MILLER (to Sinclair Refining Co.). U. S. 1,714,097, May 21. An app. is described in which the heavy oil used is heated in a body at about 300–350° in contact with a body of fuller's earth; vapors are taken off and refluxed, gasoline components are led off from the refluxing operation, reflux condensate is stripped of light components, and the stripped condensate residue is returned to the first-mentioned body of oil.

**Distilling hydrocarbon oils and treating them with gases containing hydrogen.** WILLIAM J. KNOX (to Petroleum Conversion Corp.). U. S. 1,715,239, May 28. A liquid hydrocarbon material such as a heavy petroleum distillate is heated in a treating chamber by contact with heated H-contg. gases after a preliminary partial fractionation by heat exchange with gases and vapors from the chamber; the vapors and gases from the fractional distn. are passed directly into the treating chamber. Various structural details are described.

**Dewaxing hydrocarbon oils.** ERNEST B. PHILLIPS and JAMES G. STAFFORD (to Sinclair Refining Co.). U. S. 1,714,133, May 21. An app. is described having an insulated tank with cooling coil and agitator and to which the oil to be dewaxed is supplied together with a finely divided solid material such as fuller's earth. A filter press receives material from this tank and serves to sep. oil from wax and added solid material; the wax is sepd. from the added solid by settling of the latter; the solid material is passed to a drier and dried for reuse.

**Conversion of hydrocarbon oils into lighter products.** MYRON W. COLONY (to Petroleum Conversion Corp.). U. S. 1,715,341, May 28. A mass of inert refractory heat-absorbing material is heated to a temp. above that required for the oil conversion; a carrier gas such as steam and hydrocarbon gas is passed over the material and into a reaction chamber contg. hydrocarbon material such as oil vapor undergoing treatment to effect conversion under substantially uniform temp. conditions; motor fuel is obtained from the mixed gases and vapors leaving the reaction chamber. An arrangement of app. is described.

**Cracking hydrocarbon oils.** EUGENE C. HERTHEL and HARRY L. PELZER (to Sinclair Refining Co.). U. S. 1,714,090, May 21. A body of oil is maintained at a cracking temp. and vapors are taken off under pressure; oil from the body is circulated through heating tubes externally exposed to heating gases and then back to the body; a bed of finely divided filtering material such as fuller's earth is maintained in the path of the circulating oil; a gaseous heating medium such as uncondensed hydrocarbon gases heated to a cracking temp. is introduced into the body of oil beneath the bed of finely divided filtering material. Various features of the app. are described. U. S. 1,714,091 specifies circulating a charge of oil in a pressure still from a bulk supply drum through heating tubes back to the bulk supply drum and maintaining a body of finely divided absorbent material such as fuller's earth on a support through which the oil passes in its circulation; the oil is heated to a cracking temp. in the heating tubes, vapors including the desired product are taken off under pressure, and the body of absorbent material in the bulk supply drum is subjected to agitation. Various details of app. are described. Cf. C. A. 23, 3078.

**Cracking hydrocarbon oils in the liquid phase.** STANDARD DEVELOPMENT CO. Brit. 299,683, Sept. 22, 1927. In effecting cracking in app. of the "tube and drum" type in which pairs of digestion drums are employed so that one may be cleaned while the other is in use, the drum which has just been cleaned is filled with heated oil before diverting the stream of oil passing to the drum still in use. Various structural details of the app. are described.

**Cracking hydrocarbon oil vapors in contact with mercury vapor as the sole heating agent.** C. P. TOLMAN. Brit. 299,957, Sept. 17, 1927. An arrangement of app. is described.

**Cracking oil.** ALFRED SCHWARZ (to Coal and Oil Products Corp.). U. S. 1,714,453, May 21. A mass of carbonaceous material such as coal or coke is heated to an oil-cracking temp. and waste gases produced in such heating are used to heat a body of oil to a distg. temp.; vapors are sepd. from the body of oil and unvaporized oil from the body is introduced into the mass of carbonaceous material to effect vaporization; the resulting vapors are passed downwardly through zones of increasing temp. to crack them, resulting vapors and gases are fractionated, and heavier condensed fractions are conducted to the oil body for retreatment. U. S. 1,714,454 specifies an oil-cracking app. suitable for carrying out processes such as described in U. S. 1,714,453, and in which a

gas producer to which steam is supplied serves to furnish the heated carbonaceous material for use in the oil cracking.

**Apparatus for cracking hydrocarbon oils.** WILLIAM R. HOWARD (to Universal Oil Products Co.). U. S. 1,715,066, May 28. A stream of oil is heated to a cracking temp. as it flows through a pipe coil and then passes to a compartment of an enlarged reaction zone, which is connected with a dephlegmator; reflux condensate is collected in another compartment of the enlarged reaction zone and heat is applied to the second-mentioned compartment only of the reaction zone. Pressure is maintained in the app. and various other structural details are specified. Cf. C. A. 23, 2028.

**Apparatus for cracking hydrocarbon oils.** GEORGE W. WALLACE. U. S. 1,714,198, May 21. A closed chamber filled with refractory material such as fire brick or C has a free space at its top into which a complete combustion burner leads; an oil inlet pipe passes through the burner and terminates with a spray nozzle within the space mentioned; volatile products are led off from the bottom of the chamber and may be passed to a dephlegmator.

**Heating system for heating oil-cracking stills by combustion gases.** JOSEPH F. DONNELLY. U. S. 1,714,855, May 28. Various structural details are specified.

**Preventing corrosion of condensers of oil-cracking apparatus.** JACQUE C. MORRELL and HARRY P. BENNER (to Universal Oil Products Co.). U. S. 1,715,095, May 28.  $\text{NH}_3$  soln. is added to the vapors before they enter the condenser to neutralize HCl present in the vapors leaving the cracking app. An arrangement of app. is described.

**Treating hydrocarbon residues, etc.** STANDARD DEVELOPMENT CO. Brit. 299,925, Aug. 9, 1927. Heavy products such as cracking coal tar or pressure-still tar, which ordinarily form a carbonaceous sediment on standing, are treated with "acid oil" (prepd. by dilg. with water the acid sludge formed in treating petroleum oils with acid) to ppt. the sediment. An inert material such as coke in granular form may be added to facilitate filtering and the oil is sepd. and may be used for fuel. The C residue may be extd. with a solvent such as  $\text{CS}_2$  to remove oil and asphalt and the C remaining may be used for making electrodes or as a filler with rubber compns.

**Separating hydrocarbons, etc., by fractional solution.** W. MERCK, K. MERCK, L. MERCK, W. MERCK and F. MERCK (trading as the firm of E. Merck). Brit. 300,266, Nov. 11, 1927. Constituents of lubricating oils, lignite tar oils, etc., are sepd. by adding a solvent liquid such as EtOH, PrOH, or other alc., or  $\text{CCl}_4$  of such character and at such a temp. that a homogeneous mixt. is formed, and then cooling in stages so that the different constituents are pptd. fractionally.

**Hydrocarbons and oils.** RAOUL M. BERLINE. Fr. 652,505, Feb. 11, 1928. Hydrocarbons and oils which have been purified by treatment with  $\text{H}_2\text{SO}_4$  are neutralized with gaseous  $\text{NH}_3$  instead of the usual NaOH to avoid formation of emulsions.

**Separating oils from emulsions.** STANDARD OIL DEVELOPMENT CO. Fr. 652,206, Apr. 4, 1928. Oils are sepd. from their emulsions with water by adding not more than 5% by wt. of a sulfonic acid sol. in water formed by the action of concd.  $\text{H}_2\text{SO}_4$  or oleum on a petroleum lubricating oil.

**Distilling mineral oil.** ARTHUR E. PEW, JR., and HENRY THOMAS (to Sun Oil Co.). U. S. 1,714,811, May 28. A distn. system is described in which Hg vapor is utilized for heating the oil under treatment. U. S. 1,714,812 relates to app. for the same purpose.

**Retort treatment of oil-bearing shales.** MILON J. TRUMBLE. U. S. 1,713,794, May 21. In operating a battery of retorts for treating oil-bearing shale with superheated steam, the battery is divided into sub-groups each including a plurality of retorts; each group is provided with a steam superheater. Each fresh quantity of steam is successively passed through the retorts of one sub-group, through an oil-catcher, through a superheater, and forward through the retorts of another sub-group, and finally into a vapor main. Various other details are described.

**Furnace for pyrogenous decomposition of crude oil.** V. E. GRUM-GRZHUMILO. Russ. 5739, June 20, 1928. In a metallic cylindrical vertical fire box the bell-shaped top is heated by a direct contact of a flame, which, being reflected, leaves the furnace through openings provided in the lower part. At a certain distance from the outer side of the bell is a bell-shaped cover, the rims of which are immersed in water. The oil enters through an opening in the center of the second bell, drops on the hot first bell, whereby it is decomposed into hydrogen and coke. H is withdrawn through an opening in the second bell; the coke is removed from the first bell by a mechanical scraper and drops into the water in the gas trap, from where it is removed by usual methods.

**Lubricating oils.** SWAN, HUNTER & WIGHAM RICHARDSON, LTD., and HORACE J. YOUNG. Fr. 651,968, Mar. 30, 1928. Waste lubricating oils are recovered by heating

them in contact with Zn, Al, Mg, or alloys thereof, or alloys of Ca and (or) Na with the above.

**Liquid fuel for internal combustion engines.** ASIATIC PETROLEUM CO., LTD., A. C. EGERTON and C. H. BARTON. Brit. 300,156, Aug. 6, 1927. "Knocking" of hydrocarbon fuels is checked by adding about 0.5–1.5% of compds. such as oleate, naphthenate, or "sulfonate" of Na, K, Li, Rb or Cs. The "sulfonate" may be derived by treating acid-treated petroleum fractions with KOH or  $K_2CO_3$ .

**Mixed liquid fuel suitable for internal combustion engines.** GRANT HAMMOND (to Fuel Development Corp.). U. S. 1,713,530, May 21. A light satd. liquid hydrocarbon fuel such as gasoline is mixed with 1–10% of a mixt. formed from com. EtOH 70, butanol 20 and glycerol 5 parts, in order to prevent "knocking." Cf. C. A. 23, 1248.

**Motor fuel.** EUPHIME V. BERESLAVSKY (to Ethyl Gasoline Corp.). U. S. 1,713,589, May 21. Diaminomesitylene or a similar compd. is added to fuels such as gasoline or kerosene in order to prevent "knocking."

**Gasoline from solid bituminous material.** MILON J. TRUMBLE. U. S. 1,714,963, May 28. A condensate from the distn. of solid bituminous material such as coal, lignite or shale is subjected to cracking in a cracking still; hot C from the cracking is recovered in a receptacle sep. from the still, and superheated steam and hot vapors from the cracking process and C receptacle are passed through a body of solid bituminous material for distg. volatiles from it; vapors thus formed are dephlegmated and the condensate from the dephlegmation is delivered to the cracking process, and uncondensed vapors from the dephlegmation are passed to a condenser. An arrangement of app. is described.

**Air-cooled floating roof for oil storage tanks.** CHARLES F. H. BOHNHARDT. U. S. 1,714,207, May 21. Structural features.

**Dehydrating attachment for oil flash testers.** SAMUEL E. CALVIN. U. S. 1,714,765, May 28. A closed-cup flash tester is provided with an inner receptacle for retaining a dehydrating agent such as  $CaCl_2$ , which is arranged to be in contact with vapors of the oil being tested.

**Automatic fire extinguisher for oils.** A. V. TIKHONENKO. Russ. 5711, June 30, 1928. In a tank a foam fire extinguisher is placed on a float. A plug of a low-melting alloy releases a hammer by which the acid container is broken and the foam is uniformly distributed over the surface of the oil.

**Oxidized asphaltic material.** LESTER KIRSCHBRAUN (one-half to Frank L. Belknap). U. S. 1,715,069, May 28. In prepg. a product which is of ductile rubber-like properties, petroleum residuum is mixed with air and the mixt. is passed through a long passage such as a pipe coil in which its temp. is gradually raised (suitably to about 200–350°); it is thence passed into an agitated bulk supply of the oxidation end product whence liquid oxidized asphalt is withdrawn. An app. is described.

**Asphalt emulsions.** ARTHUR L. HALVORSEN and PIERCE M. TRAVIS (to Emulsion Process Corp.). U. S. 1,714,982, May 28.  $Na_3PO_4$  not exceeding 0.75% is used for effecting emulsification of asphalt and water.

**Emulsions of bitumen.** ARNALDO CAROSELLI and HEINRICH HEINZ. Fr. 651,794, Mar. 26, 1928. Asphalts, tars, petroleum residues, etc., are emulsified with Na, K, or  $NH_4$  salts of fatty or resin acids to which org. substances, such as lower alcs. or ketones of the fatty series,  $BzOH$ , or  $PhOH$ , capable of lowering the surface tension between the bitumen and water, has been added.

**Apparatus for reclaiming journal box waste.** EDWIN S. PEARCE (to American Laundry Machinery Co.). U. S. 1,713,711, May 21. Structural features.

## 23—CELLULOSE AND PAPER

CARLETON E. CURRAN

**Cellulose.** CHAS. J. J. FOX. *Artificial Silk World* 2, 269–70(1929).—The importance of micelle size of cellulose in the manuf. and properties of artificial silk.

S. K. FORD

**The adsorption of simple aliphatic compounds by cellulose.** KURT BRASS AND JOSEF K. FREI. *Kolloid-Z.* 45, 244–55(1928).—Formic acid is adsorbed in similar manner by purified cotton, by pure cotton cellulose and by viscose. Formic and acetic acids dissolved in  $H_2O$  and in acetone give similar adsorption curves.  $CH_3ClCO_2H$ ,  $CHCl_2CO_2H$  and  $CCl_3CO_2H$  are adsorbed by viscose in a similar manner. Adsorption by viscose of  $AcOH$ ,  $EtCO_2H$ ,  $PrCO_2H$ , palmitic and stearic acids in  $H_2O$ , acetone and alc. and glycolic, phenylacetic, fumaric, maleic and phenoxyacetic acids in  $H_2O$  was

studied. Palmitic and stearic acids are not adsorbed by cellulose. Adsorption is reversible for the other fatty acids.  $\text{CH}_3\text{O}$  is not adsorbed by cellulose in acetone,  $\text{EtOH}$ , glycol, glycerol or water solns. No relation exists between mol. wt. and adsorption value. Adsorption increases as the dissocn. const. increases. Of aromatic compds., only those which show electrolytic dissocn. are adsorbed. R. H. L.

The selective action of the three hydroxyl groups of cellulose. TADASHI NAKASHIMA AND ICHIRO SAKURADA. *Bull. Inst. Phys. Chem. Research* (Tokyo) 8, 272-6; *Abstracts* 2, 33-5(1929). (In German.)—The reactions in which the OH groups of cellulose take part may be divided into 3 classes, according to whether 1, 2 or 3 OH groups enter the reaction for every  $\text{C}_4$  unit. Of the 3 OH groups of the glucose unit in cellulose, 2 are secondary (2 and 3 positions) and one is primary (position 6). N. and S. attempt to det. whether the mono-*p*-toluenesulfonic ester of cellulose is primary or secondary. Heating for 15 hrs. at  $100^\circ$  with  $\text{N}_2\text{H}_4$  hydrolyzes the ester. The formation of unsatd. compds. and of hydrazine derivs. indicates that the ester is secondary (according to theory of Freudenberg). The dibenzyl ether of cellulose can be converted into tribenzyl ether by dissolving it in  $\text{C}_6\text{H}_5\text{CH}_2\text{Cl}$  and heating with  $\text{Ag}_2\text{O}$ . G. C.

Manufacture of cellulose acetate. HELLE-STAU. *Russa* 4, 513, 515(1929).—A brief outline of the process of manuf. of cellulose acetate. A. PAPINEAU-COUTURE

Effect of aniline on cellulose triacetate. H. LEB. GRAY, T. F. MURRAY, JR. AND C. J. STAUD. *J. Am. Chem. Soc.* 51, 1810-4(1929).—Cellulose acetate (I) is saponified by heating with  $\text{PhNH}_2$  at the b. p. of the  $\text{PhNH}_2$ -I solns.; the decrease in Ac content is apparent after as short a time as 2 hrs. After 25 hrs. heating, the product is insol. in  $\text{CHCl}_3$ - $\text{EtOH}$  or  $\text{Me}_2\text{CO}$ ; after 100 hrs., the Ac content has decreased from 43.9 to 2.3%. The cellulose equiv. agrees approx. with the theoretical value. The decrease in Ac content at  $148$ – $51^\circ$  gives a curve of the same form as that obtained at the higher temp. The sp. rotation, so far as present interpretation permits, does not seem to indicate the possibility of a stereoisomeric change comparable with the mutarotation of the sugars, as suggested by Knoevenagel. The product obtained at  $183^\circ$ , upon reacylation, reverts to a product having the analytical constns. of I. The deesterifying action of  $\text{PhNH}_2$  on I at room temp. is exceedingly slow. C. J. WEST

Solvents and swelling agents for acetylcellulose. AUGUST NOLL. *Seide* 33, 404-10 (1928); cf. *C. A.* 22, 867, 4792.—A detailed survey of 35 compds. used as solvents for acetylcellulose. Phys. properties, flash points, examples for use, trade names and structural formulas are given. H. W. STIEGLER

Allylcellulose. ICHIRO SAKURADA. *Z. angew. Chem.* 42, No. 21, 549-50(1929); *Bull. Inst. Phys. Chem. Research* (Tokyo) 8, 114-7; *Abstract ed.* 2, 18.—See *C. A.* 23, 3081. E. C. M.

Cellulosamine and cellulosaniline. ICHIRO SAKURADA. *Bull. Inst. Phys. Chem. Research* (Tokyo) 8, 265-71, *Abstracts* 2, 31-3(1929). (In German.)—Cellulose mono-*p*-toluenesulfonate (I) (Kita, Nakashima and Sakurada, *C. A.* 22, 684) heated in a sealed tube for 24 hrs. with concd. aq.  $\text{NH}_3$  gives a product corresponding to 1 cellulosamine + 1 cellulose +  $\frac{1}{2}$  I. Prolonged heating does not increase the yield of the amino compd. Heating for 20 hrs. in the same way of I with an  $\text{NH}_3$  soln in abs.  $\text{EtOH}$  satd. at  $0^\circ$  gives after 20 hrs. 2 cellulosamine + 1 cellulose + 2 I. Heating I on a water bath with  $\text{C}_6\text{H}_5\text{NH}_2$  in  $\text{H}_2\text{O}$ -free glycerol gives after 20 hrs. 2 cellulosaniline + 1 cellulose + 2 I, and after 100 hrs. 2 cellulosaniline +  $\frac{1}{2}$  cellulose + 1 I. Washing of the products with  $\text{Cu-NH}_3$  soln. leaves pure cellulosamine,  $\text{C}_{12}\text{H}_{15}\text{O}_2\text{NH}_2$  and cellulosaniline,  $\text{C}_{12}\text{H}_{15}\text{O}_2\text{NHPH}$ . G. CALINGAERT

Benzyl ether of cellulose. TADASHI NAKASHIMA. *Bull. Inst. Phys. Chem. Research* (Tokyo) 8, 261-4(1929); *Abstracts* 2, 31 (1929). (In German.)—Cotton paper is dissolved in 40-50%  $\text{NaOH}$ , and then treated with 2 mols. of  $\text{C}_6\text{H}_5\text{CH}_2\text{Cl}$ , dissolved in  $\text{C}_6\text{H}_6$  or  $\text{C}_6\text{H}_5\text{Me}$ . A quant. yield of cellulose dibenzyl ether is obtained. The prepn. of higher ethers is more difficult. Alkali cellulose from a 10-20%  $\text{NaOH}$  soln. gives a product contg. only  $\frac{1}{2}$  benzyl group per  $\text{C}_4$ . By extg. the unchanged cellulose with  $\text{Cu-NH}_3$  soln. a residue of monobenzyl ether is obtained. Both ethers are sol. in  $\text{CHCl}_3$ ,  $\text{C}_6\text{H}_6$  and  $\text{CCl}_4$ , and insol. in  $\text{Et}_2\text{O}$ ,  $\text{EtOH}$  and  $\text{H}_2\text{O}$ . G. CALINGAERT

Homogeneous standard viscose with high content of pure cellulose. WILHELM A. DYER. *Seide* 34, 129-32(1929).—The needs and methods are discussed. H. W. S.

The penetration of wood by liquids. H. WYATT JOHNSTON. *Pulp Paper Mag. Can. International No.*, 342-4(Feb., 1929).—A brief summary of work carried out, chiefly on jack pine, on the penetration of liquids under various conditions. Though the results in themselves are probably of little strictly chem. interest, they may find considerable practical application in the sulfite pulping process. A. P.-C.

Adsorption of gases and vapors by wood. LLOYD M. PROCTOR. *Pulp Paper Mag.*

**Can. International No., 344 (Feb., 1929).**—The large mass of the gas contained in the wood was found to have the same compn. as air, and to be simply filling the cavities; the portion of gas obtained after the gas filling the cavities has been removed is actually adsorbed on the walls of the wood structure and has not the same compn. as air, *i. e.*, it is selectively adsorbed. The adsorption of vapors was studied by means of a quartz spring balance which permitted of measuring differences in wt. on a 0.15-g. sample to an accuracy of 0.3%. The equil. values throughout a wide range of temps. for vapor pressures ranging from 0.1 mm. to the satn. value were measured. At high temps. the equil. value is completely reversible, while at low temp. an apparent hysteresis is noticed; this is most pronounced when the sample has been subjected to excessive drying, but even then a truly reversible value may be obtained. A. P.-C.

**Method of testing clay, talc and agalite.** D. D. UONG. *Paper Trade J.* 88, No. 11, 55-6(1929).—A description of the proposed official methods of the Technical Assoc. of the Pulp and Paper Industry. A. PAPINEAU-COUTURE

**Moisture content of English coating clays.** R. M. COBB and DONALD V. LOWE. *Paper Trade J.* 88, No. 11, 56-7(1929).—Clay received in America with a moisture content above 9% cannot have picked up H<sub>2</sub>O in crossing the Atlantic, because clays dry out in an atm. of 100% relative humidity to a moisture content of 9% or less. No injury to coating clays results if they are heated to 105° to drive off all H<sub>2</sub>O. The difference between the H<sub>2</sub>O of wet and previously dried clays at the same relative humidity results from drying out of the capillaries and increasing the radius of curvature of the liquids in the capillaries. A. PAPINEAU-COUTURE

Effect of cathode rays on paper (SCHOEFFLE, CONNELL) 3. Proposed method for testing casein (MILHAM) 18. Acylation of multivalent ether-alcohols (Fr. pat. 652,383) 10. Printing ink suitable for use on rubber, celluloid, etc. (U. S. pat. 1,715,209) 26. Emulsions for use as detergents [in paper industry] (Brit. pat. 299,817) 18.

**Saccharifying cellulose.** INTERNATIONAL SUGAR & ALCOHOL CO., LTD. Brit. 299,844, Nov. 2, 1927. In a diffusion treatment of cellulosic material with HCl, the material is pre-mashed in a mixer with part of the total acid used and then transferred to the diffuser. Proportioning of the acid is so regulated that a temp. of 25-30° is developed in the diffuser. An acid soln. of partially hydrolyzed cellulose from a previous operation may be used for the pre-mashing. Cf. C. A. 22, 2680.

**Cellulose derivatives and products resembling cork.** I. G. FARBERIND. A.-G. Brit. 300,207, Nov. 8, 1927. Products resembling cork are obtained by treating cellulose or a cellulose compd. still contg. at least one reactive OH group with one or more chlorides of an "estolidic acid" and one or more chlorides of higher aliphatic acids or derivs., *e. g.*, cellulose, lauryl chloride, PhCl, polyricinyl chloride and pyridine are heated together at 125-30° for 90 mins. The product may be molded under pressure while heated. Dyes, fillers, etc., may be added.

**Solvent for nitrocellulose.** LOUIS E. CLEMENT (to DuPont-Pathe Film Mfg. Corp.). U. S. 1,713,512, May 21. A soln. suitable for making films, artificial silk, etc., is formed of nitrocellulose with a solvent comprising anhydrous EtOH 80 and pure acetone 20 parts by volume.

**Softeners for cellulose-ester compositions.** E. I. DUPONT DE NEMOURS & Co. and NOBEL INDUSTRIES, LTD. Brit. 300,157, May 5, 1927. Coconut oil is treated to form a product contg. mixed glycerides of the oil acids and acetic, formic or propionic acid. In treating cellulose acetate, the softener is used with another solvent softener such as triacetin.

**Solvent for acetylcellulose.** LOUIS E. CLEMENT (to DuPont-Pathe Film Mfg. Corp.). U. S. 1,713,997, May 21. A solvent comprising equal parts by vol. of pure acetone and anhyd. EtOH is used for making films, artificial silk or other products.

**Recovery of camphor.** RICHARD VAN REES. Fr. 652,009, Mar. 30, 1928. Camphor is recovered particularly from waste celluloid by decomposing the latter with alkali hydroxide and distg. the liberated camphor with steam, the 2 operations being combined by passing steam up through the celluloid while a soln. of hydroxide, *e. g.*, 20% NaOH, is passed down.

**Artificial silk.** FR. KÜTTNER A.-G. Fr. 650,848, Mar. 14, 1928. The cakes of artificial silk obtained by "pot" spinning are flattened out before rinsing. The original shape of the cake may be restored before further treatment. Cf. C. A. 23, 3099.

**Artificial silk.** F. KÜTTNER A.-G. Brit. 300,131, Nov. 5, 1927. Flattened cakes of artificial silk made by the centrifuge spinning process as described in Brit. 287,097 (C. A. 23, 530) are dried before the threads are unwound and reeled or spooled.

**Artificial silk.** LA SOIE DE CHATILLON (Soc. anon. Italiana). Fr. 652,035, Mar. 2, 1928. The winding of the finished or half finished thread during or after spinning is carried out so that the bundles of thread are crossed, leaving intervals between the spirals whereby passage of fluids through the threads is facilitated.

**Perforated bobbins for treatment of artificial silk.** I. G. FARBERIND. A.-G. 652,068, Apr. 2, 1928. The perforated bobbins on which artificial silk is treated with various liquids have a cushion of fibrous material and (or) a covering of rubber or other elastic material.

**Apparatus for "dry spinning" of filaments from solutions of cellulose esters and ethers.** M. KLEIN (to Ruth-Aldo Co.). Brit. 300,166, Nov. 7, 1927. An app. of the general type described in Brit. 292,608 (C. A. 23, 1505) is modified so that each zone of the spinning cell is provided with orifices for the admission and discharge of air, each zone having an independent air circulation. Various structural details are described.

**Hollow rayon fibers.** WALTER O. SNELLING. U. S. 1,713,679, May 21. After forming a preliminary fiber, the latter is brought into contact with a thin film of a coating agent such as a cellulose deriv. soln., carried on a rotating roller or other suitable support, the liquid coating is solidified (suitably by a coagulating bath) and the preliminary fiber is then dissolved. An arrangement of app. is described.

**Producing a curl or wave in artificial filaments.** W. SEVER and J. B. SPEAKMAN. Brit. 300,221, July 9, 1927. Fibers with a wave or curl resembling that of natural wool or cotton are obtained by extruding a fiber-forming soln. through a spinneret into a coagulating medium to which a swirling or eddying motion is imparted.

**Vegetable fiber.** ALFRED TINGLE. U. S. 1,714,831, May 28. Fibrous vegetable material such as spruce chips is digested in an aq. soln. of lime and S and then treated with a lime-eliminating material such as  $H_2SO_4$ .

**Softening wood, straw, grass or other vegetable fibers.** SIDNEY D. WELLS (to Paper Mill Laboratories, Inc.). U. S. 1,714,459, May 21. Softening is effected by spent liquors from pulp-cooking processes using NaOH "free from more powerful chemicals" and contg.  $Na_2CO_3$  and the material may be used without further refining and in the presence of S.

**Fiber board.** WILLIAM M. SHOEMAKER, JR. (to National Vulcanized Fiber Co.). U. S. 1,714,640, May 28. A soln. such as a 70° B $\acute{e}$ .  $ZnCl_2$  soln. is projected simultaneously against opposite sides of each of a plurality of cellulose paper sheets at from room temp. to about 35° and the sheets are joined under pressure. U. S. 1,714,641 relates to app. for use in such processes. Cf. C. A. 22, 3301.

**Paper pulp.** H. KUMAGAWA and K. SHIMOMURA. Brit. 299,740, June 30, 1927. Material contg. pithy fiber such as cane-sugar bagasses or kaoliang straw is beaten in a hollander with a constant flow of water to remove the sugar and other water-sol. substances and to sep. the thin and short pithy fibers. The long fibers are suspended in the water and the short pithy fibers float on the surface; the long fibers, alone or with a regulated admixture of short fibers, are collected for use as pulp.

**Paper pulp.** G. A. MOURLAQUE. Brit. 299,965, Sept. 24, 1927. See Fr. 639,900 (C. A. 23, 982).

**Paper pulp.** ROGER G. SMITH. U. S. 1,715,310, May 28. After digestion and before beating, paper pulp is treated with an aq. soln. of a sulfate and an acid such as  $Na_2SO_4$  and  $H_2SO_4$  in order to remove undesirable org. substances.

**Apparatus for draining, drying and molding paper pulp.** CHARLES J. KEENAN, EUGENE P. KENNEDY and GEORGE H. KIRSCH (to Alaska Pulp and Paper Co.). U. S. reissue 17,303, May 28. Reissue of original pat. No. 1,621,671 (C. A. 21, 1548).

**Rotary "refiner" for paper pulp, etc.** EDMUND P. ARPIN, JR. U. S. 1,714,752, May 28.

**Heating and ventilation of paper-pulp-grinding buildings.** EMIL A. BRINER. U. S. 1,713,510, May 21. Air adjacent to machinery for grinding wood with water, and adjacent to the pulp, is confined in a passageway through which the air from the structure is exhausted; fresh air admitted to the room is heated by the exhaust air.

**Paper making.** LEVIS M. BOOTH. U. S. 1,713,642, May 21.  $Al_2(SO_4)_3$  and  $Na_2CO_3$  or other suitable substances which react to form a metallic hydroxide are added to paper-making stock after addn. of size and size-pptg. agents to the stock and at or before delivery to the paper making app., in order to improve and facilitate the sizing.

**Paper making apparatus.** CHARLES E. POPE (to Great Northern Paper Co.). U. S. 1,714,238, May 21. Structural features.

**Paper-making apparatus.** CHARLES W. VALENTINE and ALFRED F. HELIN (to Bagley and Sewall Co.). U. S. 1,713,988, May 21. Structural features.

**Sizing paper, etc.** HUGH M. SPENCER. U. S. 1,714,052, May 21. Coagulation of a rosin emulsion is effected by admixture of a peptized colloidal soln. of  $\text{Al}(\text{OH})_3$ .

**Impregnating paper for bag manufacture, etc.** ALFRED HOLTER. U. S. 1,714,222, May 21. Paper is prepd. for subsequent folding and forming by impregnating one surface of a paper web with an aq. soln. of a material such as soap and glue which can react with sol. Al compds. to form insol. reaction products, and impregnating a second web with a soln. contg. alum or other sol. Al compd., and then bringing the 2 surfaces into contact with each other immediately prior to folding or otherwise fabricating into webs (without drying prior to folding).

## 24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

**The ignition temperature of several aromatic nitro explosives.** S. MICEWICZ AND K. MAJKOWSKI. *Z. ges. Schiess- u. Sprengstoffw.* 23, 422-7(1928). See C. A. 22, 4249.

C. G. STORM

**The use of lead and its compounds in the chemistry of explosives.** L. METZ. *Metallwirtschaft* 7, 228-30(1928).—Pb is used as testing material for explosives.  $\text{Pb}(\text{N}_3)_2$  is frequently used as priming but it has certain disadvantages as compared with mercuric fulminate. The thiosulfate, thiocyanate and trinitroresorcinolate of Pb are also in use.

EMIL KLARMANN

**Safety measures in chemical works.** ANON. *Chem. Age* (London) 20, 441 (1929).—The Assoc. of Brit. Chem. Mfrs. propose to issue a set of model safety rules in two pts., Pt. I covering Principles and Pt. II, Detailed Instructions. C. E. M.

**What do we know about the explosibility of coal dust in mines?** H. P. GREENWALD. *Bur. Mines, Circ.* No. 6112, 7 pp.(1929).—A statement is given of factors involved with a discussion of each but no summary of conclusions. C. E. M.

**The limit of inflammability of gaseous mixtures.** J. CHAPPUIS AND A. PIGNOT. *Chimie & industrie Special No.*, 228-30(Feb., 1929).—The limit of inflammability of  $\text{CH}_4$ -air mixts. increases appreciably with increase in pressure up to 15-20 kg. per sq. cm., and only slowly above this point. The app. used was similar to that used by Caillietet for the liquefaction of gases, but modified so as to obtain a larger working vol.

A. PAFINEAU-COUTURE

**Extinguishing gas (line) fires without water.** NEUMANN. *Gas u. Wasserfach* 72, 305(1929).—Fire extinguishers of the liquid  $\text{CO}_2$  (snow) type have been used to extinguish gas fires occurring along mains. Three extinguishers, each contg. about 10 lbs. of liquid  $\text{CO}_2$ , were used successfully to extinguish a flame from a saw-cut half through a 4-in. pipe, with a gas pressure of about 40 in. of water. The extinguisher nozzle should be held very near the fire and several app. used simultaneously, if possible.

R. W. RYAN

**Explosion in nitroglycerin paste mixing house.** H. F. WATTS. *Special Rept.* No. 243, H. M. Insp. of Explosions Mimeograph, 11 pp., Apr., 1929.—The explosion occurred Oct. 15, 1928 at the factory of the Explosives and Chem. Products, Ltd., Great Oakley, Essex, England, causing the death of 5 persons. In the building were 3 mixing and 2 extruding machines, one of each variety being in use at the time of the accident. It was thought most probable the explosion originated in the heated mixing machine and was due to the breaking of the blades of the mixer, or the shearing off of a cotter-bolt, or to volatilized ethylene glycol dinitrate from the paste condensing on some part of the moving machinery. The account of expts. made and of the recommendations offered are of interest. In rebuilding the 2 operations are to be conducted in sep. buildings.

CHARLES E. MUNROE

**New type of laboratory dust-explosion apparatus.** C. M. BOUTON, C. H. GILMOUR AND GARNET PHILLIPS. *Bur. Mines, Repts. of Investigations* No. 2927, 10 pp.(1929).—An illustrated description of the device, with directions for operating it and treatment of the data, accompanied by a discussion of the general subject. C. E. M.

**Explosions while granulating copper.** W. STAHL. *Metallbörse* 19, 205(1929).—If the Cu be not too hot, the steam not too rapid and the mass kept stirred, explosions are reduced to a minimum.

W. C. EBAUGH

**Study of the double bonds in petrolatums [in relation to value as stabilizer in storing smokeless powder] (POGGI) 22.**

**Explosives for blasting coal, etc.** B. I. STROORS (to Hercules Powder Co.). Brit. 299,862, Nov. 4, 1927. A carbonaceous material of low d. such as sawdust of balsa wood or Congo wood is impregnated with a salt such as a nitrate or perchlorate which is preferably first mixed with a salt contg. water of crystn. such as  $Mg(NO_3)_2$ ,  $Ca(NO_3)_2$ ,  $Fe(NO_3)_3$ , or Al nitrate, heated to release the water of crystn. and then used as a melt for the impregnation. Sensitizers such as nitroglycerin or nitropolyglycerin may be added. Cf. C. A. 22, 2665.

**Use of moss as an absorbent for dynamite manufacture.** CHARLES O. BLACK and WILLIAM A. MOORE (to E. I. du Pont de Nemours & Co.). U. S. 1,713,816, May 21. Moss such as sphagnum is used.

## 25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

**Advances in dye chemistry in 1928.** F. MAYER. *Chem.-Ztg.* 53, No. 43, *Fortschrittsber.* 41-61(1929). E. H.

**Interesting sources of natural dyestuffs.** C. D. MELL. *Textile Colorist* 51, 401-4 (1929); cf. C. A. 23, 3347.—Natural dyestuffs are obtained from the root bark of the arnatto plant (*Bixa orellana*), the bark of pito (*Erythrina corallodendron*), the bark of the caobillo tree and from the root bark of mountain mahogany (*Cercocarpus parvifolius*). RUBY K. WORNER

**Application of the method of analyzing colors to the examination of pigments and lakes.** A. G. GREEN. *Rev. gén. mat. color.* 32, 93-9(1928). R. HOUGHTON

**Application of collodion membranes to the separation and analysis of coloring matters.** GEORGE GENIN. *Rev. gén. mat. color.* 32, 2-3, 20-2(1928).—Cellulose esters in porous form remove certain coloring matters from soln. very completely and quickly. Basic colors are adsorbed. Acid colors are usually not adsorbed, but the colloidal condition of the dye in soln. influences the behavior. The affinity of the esters for basic dyes is variously ascribed to presence of oxycellulose or to acid radicals (sulfate, acetate, etc.). Theories are discussed with a view to applying cellulose and its esters to identification of dyestuffs in com. mixts. Three forms of ultra-filter of lab. type available in France are described. Descriptions of cases of actual application of this technic to sepn. of specific dyestuffs from mixts. are omitted. E. M. SHELTON

**The effect of sulfurous acid on azoic colors and a new method for testing fastness to sulfuring.** A. T. KING. *Rev. gén. mat. color.* 32, 106-8, 142-6(1928).—The degree of conversion of azoic colors dyed on wool into azo-sulfites (having slightly different shades) by exposure to  $SO_2$  is entirely dependent on the amt. of alkali in the cloth. Samples must be brought to a definite degree of alky. (Bromothymol Blue being used) before tests for fastness to sulfuring are reliable. H. F. LEUPOLD

**Application of the insoluble azo colors in printing.** WM. H. COTTON. *Proc. Am. Assoc. Textile Chem. and Colorists; Am. Dyestuff Repr.* 18, 288-92(1929).—A review is given of the development of this class of colors and of methods of printing on cotton for the production of various colored effects. E. W. CLARK

**Naphthols and rapid fast colors in printing.** H. E. HAGER. *Proc. Am. Assoc. Textile Chem. and Colorists; Am. Dyestuff Repr.* 18, 255-9(1929).—Printing with the Naphthol AS colors is divided into 3 groups, the discharge and resist style, the rapid fast colors and the naphthol print-on style. Vat colors are suitable for colored discharges and equal the fastness of the naphthol grounds. Most naphthol grounds are stable to  $NaClO_2$  and can be used in the chlorate discharge style. Uses of Blue Salt B, Variamine Blue Salt and resist combinations are described. Naphthol resists under aniline blacks give very bright effects. The goods are padded with aniline soln., dried and printed with  $ZnO$ - $NaOH$  resist contg. the naphthol, then aged in dry steam and padded in a fast color salt soln. The rapid fast colors are mixts of certain naphthols with the nitrosamines of certain bases in an alk. medium. They are suitable for all cotton fabrics, for most rayons, Bemberg and Tubize, but do not print well on silk and not at all on Celanese. The Rapidogenes and H brands give stable printing pastes. The fastness of this group is very good. The indigosols may be used to complete the range of shades. When used in combination with the indigosols, oxalic or formic acid is used for developing. Combinations of the rapid fast colors with basic, chrome and vat colors are described and formulas given. E. W. C.

**Dyeing without the use of coloring matters.** P. BRUNAN. *Ann. fals.* 22, 132-9 (1929).—A discussion of the Escaich-Worms process of dyeing (C. A. 19, 1351, 2750,

3165, 3279, 3599; 20, 1528; 22, 1481), and more particularly of its advantages.

**The production of greens in dyeing.** RENÉ TOUSSAINT. *Têta* 7, 373-89(1929).—A discussion of the difficulties encountered in correcting shades, due to the fact that there are practically no dyes giving pure colors, with a plea for dye manufacturers to develop such dyes.

**Dyeing of knitted goods containing mixed fibers.** W. A. EDWARDS AND G. A. HARDCASTLE. *Rev. gén. mat. color.* 32, 121-3(1928).—General. R. HOUGHTON  
**Indigosol resists on chrome and alizarin colors.** J. BERT. *Dyer, Calico Printer* 61, 161(1929).—Formulas are given.

**Whites and light shades tainted by strong acid gases.** GEORGE RICE. *Dyer, Calico Printer* 61, 160-1(1929).—A blow-off attachment to care for gaseous discharges from the agers and a ventilating hood are described.

**The effects of after-treatments on the degree of aggregation, location, shade and fastness-properties of insoluble azo colors on the fiber.** PERCY BEAN AND F. M. ROWE. *J. Soc. Dyers Colourists* 45, 67-76(1929).—Max. increase in fastness to light is a function of the more or less extensive hot after-treatment of the dyed material. Hot alk. after-treatment is more rapid in increasing the fastness to light and rubbing. Change in shade is due to increased size of pigment particles by moist heat with increased light fastness or decreased size of pigment particles by dry heat with lowered light fastness. After-treatment of dyed artificial silks has the effect of blinding the luster. There is an insert of 24 photomicrographic plates showing aggregation of pigment particles following different after-treatments.

**Modern piece and skein dyeing machines.** KURT GÖTZE. *Seide* 34, 88-96(1929).—A survey, giving illustrations of many types of silk-dyeing app. H. W. S.

**The dyeing of silk (organzine and tram) "Fast to sun and rain."** RAYMOND CURTIS. *Am. Dyestuff Rept.* 18, 171-3, 198(1929).—Tannin weighting methods and selection of dyes to produce colors fast to sun and rain under standard tests are discussed.

**Instructive ideas in silk dyeing.** THOMAS F. HUGHES. *Textile Colorist* 51, 380-3(1929).—Practical.

**The dyeing of pure silk hose.** H. D. MUDFORD. *J. Soc. Dyers Colourists* 45, 107-10(1929).—A paper presenting the methods of prepn. and dyeing of pure silk hose with acid and direct colors, some of which are fast to washing.

**Remarks on troubles encountered in the hosiery dyehouse.** DANIEL MCGOWAN. *Proc. Am. Assoc. Textile Chem. and Colorists; Am. Dyestuff Repr.* 18, 206-8(1929).

**Recent progress in artificial-silk dyeing.** L. G. LAWRIE. *Artificial Silk World* 2, 187-9(1929).—The causes for the uneven absorption of dyestuffs by regenerated cellulose fibers, the selection of suitable colors to overcome these defects and a patented method for correcting uneven dyeings consisting of treating the dyed material 30 mins. in a bath contg. 1% of  $\beta$ -naphthol and 1% of NaCl at 195° F. are discussed. The absorption of the mordant "Katanol O" by rayons appears to be at a max. when 5% "Katanol O" and 1%  $\text{Na}_2\text{CO}_3$  are used. It is necessary to sour the mordanted material with dil. AcOH to prevent it from washing out. For dyeing cellulose acetate rayons, insol. dyes which are in a dispersed state are used. "Duranol," "Dispersol" and "Cel-liton" dyes are of this type. Two new patented methods of mordanting acetate rayon are described. B. P. 273,692 relates to the use of  $\text{FeCl}_3$ , while B. P. 273,695 describes the use of swelling agents as formic or acetic acid, furfuraldehyde, phenol or pyridine.

**Dyeing black on artificial silk and cotton materials.** A. J. HALL. *Dyer, Calico Printer* 61, 162-3(1929).—Sulfur and direct colors, Naphthol AS and vat dyes, and S. R. A., Celatene, Dispersol and aniline blacks are considered from a practical viewpoint.

**Conditions for the even stripping of rayons (except acetate silk) dyed with substantive dyes. IV. The dyeing of rayons.** W. WELTZER AND K. GÖTZE. *Seide* 34, 136-43(1929).—For even dyeing, the degree of dispersion is of little importance. With several substantive dyes, the influence of temp. on the amt. absorbed is detd. and a definite relationship between max. absorption at medium temps. and evenness is established. In testing for evenness, the same dye should be compared on several fibers. The relations between capillarity, dye absorption and levelness are simplified and for the first time, simple rules are given for the dependence of simultaneous stripping on dyeing conditions. Some deductions for the dyeing of mixed fibers are discussed. Increasing evenness by means of after-treatment is discussed.

**The coloring of cellulose acetate solutions.** C. F. J. NEWBY. *J. Soc. Dyers Colourists* 45, 104-7(1929).—Types of colors used are pigments, dyes, metallic and colored bronzes. Mixing of pigments with the vehicle, solvents used and maturing of the medium before and after coloring are described. ROBERT HOUGHTON

**The microscopical examination of fibers.** W. GARNER. *Ind. Chemist* 5, 147-52, 155(1929).—Detailed methods of mounting various fibers are given. Much information on methods of examn. of silks, rayons, worsted, mohair, cashmere, alpaca, camel hair, cow hair, jute, hemp, esparto, flax, ramie, cotton and mercerized cotton are given. A method of cutting cross sections of fibers for microchem. examn. is described. Fifteen photomicrographs of fibers are included. E. G. R. ARDAGH

**The application of naphthols on textile fibers.** I. Dyeing. R. W. MARSSON. *Am. Dyestuff Repr.* 18, 249-55(1929).—The application of some new naphthols and developers and the dyeing of naphthols in combination with vat and sulfur colors. ROBERT HOUGHTON

**Starches used in the textile industry.** ALBERT H. GRIMSHAW. *Proc. Am. Assoc. Textile Chem. and Colorists; Am. Dyestuff Repr.* 18, 180-6(1929).—G. describes the prepn., uses and tests employed to identify type and quality of common starches in the textile trade. A. K. JOHNSON

**Stiffness in fabrics produced by different starches and starch mixtures, and a quantitative method for evaluating stiffness.** ESTHER C. PETERSON and TOBIAS DANTZIG. *U. S. Dept. Agr., Tech. Bull.* No. 108, 29 pp.(April, 1929).—An attempt is being made in the Bur. of Home Economics to differentiate and define the individual properties of a sized fabric which collectively constitute its "feel." A phys. method and app. have been developed for measuring quantitatively the stiffness of materials, which is the property considered in this communication. The mathematical basis for this method and comparative stiffening values on a cotton fabric of starches from wheat, rice, corn and potato are reported. Of these starches, a com. wheat produced the stiffest fabric, potato the least stiff and the lab.-prepd. wheat, corn and rice practically the same effect. The stiffening properties of the same species of starch are dependent upon the origin, 3 different values being obtained for 4 corn starch samples differing in this respect. No appreciable effect was observed when the time of heating the starch paste was varied from 5 to 60 mins. Preliminary studies of the effect on starch paste of concn. and addn. of foreign substances indicated that, with potato starch, no decrease was observed until the concn. had been reduced to approx. 17% of the original. This difference may be explained by the very viscous character of the potato starch paste. Addn. to the corn starch paste of borax increased its stiffening power up to a max. of 20% of the wt. of the starch, when a decrease occurred, while addn. to it of salt, paraffin, beeswax and hydrogenated vegetable oil up to 27% of the wt. of the starch had no appreciable effect. Projected strips of starched fabrics bend under their own weight according to elastic laws and assume a curve, the shape of a quartic parabola, expressed by the formula,  $\bar{y} = -(\omega/4l^3)\bar{x}^4$ , where  $\bar{x}$  and  $\bar{y}$  are the coordinates when the vertex of the parabola is at the free end of the projected strip and the  $x$  and  $y$  axes are the tangent and normal, resp., at the free end. From this, it is shown that the stiffness of the projected strip is proportional to the cube root of the elastic modulus given by the equation  $c^3 = (Eh^3/12w)$  and to the length of the radius vector as expressed by the equation  $c^3 = (\cos(4/3)\theta/80)r^3$ . A detailed description of the methods used for desizing the fabrics and prepg. the starches and starch pastes is included. RUBY K. WORNER

**A contribution to the theory of mercerization: The action of sodium hydroxide on partially methylated cellulose; the preferential absorption and heat evolution.** FREDERICK C. WOOD and AGNES C. ALEXANDER. *J. Soc. Chem. Ind.* 47, 357-61T(1928).—The following expression due to Coward and Spencer (*C. A.* 17, 1553) should be applied in detg. the amt. of preferential absorption of caustic alkali by finding the change in wt. concn. of the soln.:  $100(w/g) [(p - p')/(100 - p')]$ , where  $w$  = wt. of original soln. taken,  $g$  = wt. of dry cellulosic material used,  $p$  = g. of NaOH per 100 g. of soln. initially present and  $p'$  = g. of NaOH per 100 g. of soln. finally present. By means of a curve  $W$  and  $A$ . present the results of expts. on the properties of methylated cellulose and give values for (1) hygroscopic moisture taken up at 66% relative humidity, (2) methoxyl content, (3) hydration capacity and (4) direct dyestuff held. The exptl. methods used are described in considerable detail. Data and curves show the preferential absorption of NaOH. The following conclusions were drawn: (1) Great swelling occurs at 16° in solns. of about 9% NaOH by wt. (2) The preferential absorption of NaOH is greatly diminished with methylated cellulose. (3) There is apparently a horizontal portion of the curve between 15 and 22%

NaOH by wt., but more points would be required to substantiate this. Data are given for the following (expressed on 100 g. of dry cellulosic material): wt. of liquor held, NaOH held, H<sub>2</sub>O held, vol. of liquor held, preferential absorption of NaOH. The app. of Barratt and Lewis (*C. A.* 16, 3545) was used for measuring the heat of reaction between partly methylated cellulose and caustic soda solns. The following data are presented: (1) evolution of heat with anhyd. scoured Egyptian cotton sliver, and (2) evolution of heat with anhyd. methylated cotton (12-14% OMe). A table of values is given for absorption and desorption of water vapor at 16° by partly methylated cellulose previously dried at 105°. It appears probable that degradation (or depolymerization) of cellulose may be accompanied by an increased preferential absorption of caustic soda from aq. soln. The preferential absorption of the alkali by cellulosic material seems to be a function of the hydroxyl groups present. A. J. MONACK

**Schreiner calendering: successfully conducting the major and minor operations.** HAROLD D. CHASE. *Textile World* 75, 3831, 3891-3(1929). RUBY K. WORTNER

**The application of logwood to silk.** DAVID WALLACE. *Am. Dyestuff Repr.* 18, 212-8(1929).—A paper describing the application of logwood to unweighted and weighted silk. The weighting of silk by the use of logwood and tannin exts. with formulas for the production of blacks and the weighting of silk are given. R. H.

**Problems of the loading of natural silk.** J. BRUYAS. *Russa* 4, 557(1929).—Rough "feel" of loaded silk is attributed to insufficient washing before and after passing through the phosphate baths. A. PAPINEAU-COUTURE

**Problems of the loading of natural silk.** LOUIS SAUZAY. *Russa* 4, 39-49, 205-17, 375-89(1929).—A discussion of modern silk-loading processes, of quant. and qual. methods of testing loaded silk, and of the strengthening and recovery of loading baths. A. PAPINEAU-COUTURE

**The effect of storage on weighted silks.** P. HEERMANN. *Seide* 34, 23-7(1929).—Various weighted and dyed silks were packed to exclude light and dust and were stored at normal room temp. and moisture for a period of 3 years. Strength tests made each year showed little loss of strength in the more lightly weighted fabrics. Heavily weighted black dyed samples showed appreciable loss in strength. Loss in stretch was decided and was in proportion to the amt. of weighting. Light shades lost about 20% in 3 years. Heavy shades lost 35 to 50%. Light monopole black lost 20%; 150% weighted lost 55 and 200% weighted lost 80%. Conclusion: Loss in strength during storage is not as serious as is generally believed. Loss in stretch, however, is marked. Curves and tables are given. H. W. STIEGLER

**Artificial silks.** MARTIN BATTEGAY. *Bull. soc. ind. Mulhouse* 95, 171-301 (1929).—A review. A. PAPINEAU-COUTURE

**Differentiation of rayons.** P. PICAVET. *Russa* 5, 539(1929).—P. concludes from the examn. by ultra-violet light of different types of com. rayons, which were not subjected to any treatment before examn., that the differences in fluorescence are not sufficiently sharp to enable rayons to be identified with certainty. A. P.-C.

**The sizing and desizing of artificial silks.** KURT GÖTZE. *Seide* 34, 56-8(1929).—A survey, giving formulas, machine methods and methods of analysis for sizing. H. W. STIEGLER

**The desizing of cotton and rayon piece goods.** THOMAS F. HUGHES. *Am. Dyestuff Repr.* 18, 307-8(1929).—The use of dry concd. enzymes, which are supposed to act rapidly, is suggested for desizing. A. K. JOHNSON

**Comparison of some chemical and physical properties of cotton and viscose silk.** A. J. HALL. *J. Soc. Dyers Colourists* 45, 98-104(1929).—When treated with caustic soda (in comparison to cotton), viscose silk swells more, contracts more in length, suffers less change in affinity for dyestuffs (except certain ones) and less alteration in hygroscopic moisture nature (remaining about 11%) and has greater soly. The harmful action of caustic soda on the handle, luster and tensile strength of viscose decreases with increase of temp. Cotton yarn dyed under tension is invariably lighter in shade than when dyed with less tension; viscose shows variation with certain dyes only. Classifications of direct dyes according to differences in affinity toward viscose whether untreated or alkali-treated, or dyed with or without tension are practically in complete agreement with existing classification of "even and uneven-dyeing" dyes for commercially unequal grades of viscose silk. The suitability of a direct dye for use with unequal grades of viscose may be rapidly and accurately detd. by dyeing untreated and alkali-treated viscose; if both are dyed equally well in shade, the dye is suitable. A. K. JOHNSON

**The tensile strength and fluidity of chemically modified cotton.** DOUGLAS A. CLIBBENS AND BERT P. RIDGE. *J. Textile Inst.* 19, T389-404(1928).—Tables and

curves are given showing the relation between increase of fluidity in 0.5% cuprammonium soln. at 20° and % loss of strength of chemically modified cotton yarn. The results of about 25,000 single thread breaking strengths of yarns made from 40's ring spun warp of combed Sakel (Egyptian) cotton are summarized. The yarn was sampled by the "cut skein" method in which alternate threads served as controls. The actions of the following chem. agents were examd.: HCl and H<sub>2</sub>SO<sub>4</sub> under widely different conditions, 0.04 *N* NaClO with 0.2 *N* Na<sub>2</sub>CO<sub>3</sub> ( $p_H$  11.2), 0.04 *N* NaClO with neutral phosphate buffer ( $p_H$  7), 0.01 *N* alk. hypobromite with 0.1 *N* NaOH, and 0.04 *N* dichromate in the presence of 0.2 *N* H<sub>2</sub>SO<sub>4</sub> or 0.2 *N* oxalic acid, at 25° for different periods upon yarns with or without boiling with different alkalies before and after chem. modification. Increasingly severe treatment caused increasing fluidities accompanied by increasing loss of strength. Concd. HCl or H<sub>2</sub>SO<sub>4</sub> at ordinary temp. or dil. acids at the boil caused approx. the same loss of strength. Similarly the tendering is the same whether caused by alk. hypobromite or hypochlorite in neutral or alk. soln. The same fluidity corresponds, however, with slightly greater tendering by acids than by hypochlorite. Nearly straight lines are obtained on plotting fluidity against loss of strength caused either by acid or hypochlorite attack. The loss of strength for a given rise of fluidity is much less for yarns attacked by dichromate together with H<sub>2</sub>SO<sub>4</sub> or oxalic acid. The acids thus used were of such concn. as to cause no detectable loss of strength without the dichromate. Yarns tendered by acids or alk. hypochlorite suffer only slight addnl. tendering when subsequently keir-boiled (6 hrs., 1% NaOH, 20 lbs. excess pressure), but yarns tendered by neutral hypochlorite suffer great addnl. tendering and the loss of strength is still greater when modification has been caused by dichromate together with H<sub>2</sub>SO<sub>4</sub> or oxalic acid. Yarns oxidized with dichromate with oxalic acid show increasing loss of strength with subsequent increasing alk. of the liquid but even very mild conditions produce greatly enhanced tendering. The normal mercerization process produces effects similar to alk. boils. Boiling unmodified yarns in alkalies produces a slight loss of strength but hardly greater than the exptl. errors of mech. testing. Strength, Cu no. (Schwalbe Braid) and wt. of oxidized yarn are reduced to a greater strength the more alk. the boil, but even boiling in water for 6 hrs. reduces the strength of modified cotton without much effect upon its Cu no. and without causing much loss of material. Cu nos. are therefore valueless as a chem. measure of modified cotton. All mech. testing was done at about 70° F. and 70% relative humidity.

C. H. BADGER

Kier-bleaching cotton with peroxides. T. E. BELL. *Proc. Am. Assoc. Textile Chem. and Colorists; Am. Dyestuff Repr.* 18, 293-5(1929).—Application and control of proper chemicals to the particular fabric as well as mech. details are essential to efficient kier-bleaching of cotton with peroxides.

H. LEUPOLD

Staining, tendering and other faults in cotton-cloth bleaching. THOMAS F. HUGHES. *Textile World* 75, 3821-9(1929).—Suggestions are given concerning causes and remedies of defects in bleaching.

RUBY K. WORNER

Properties of wool. L. MEUNIER AND G. REV. *Halle aux cuirs* 1929, 137-48; cf. C. A. 22, 1047, 1479, 4829.—Swelling of wool as a function of  $p_H$  value. Effect of salts on swelling.—Hanks of degreased wool were immersed for 48 hrs. at 18-20°, in normal solns. of salts, then centrifuged and weighed. The gain in wt. was taken as the measure of swelling. Results for Na salts were: NaI 59, NaSCN 56.5, NaBrO<sub>3</sub> 52, NaNO<sub>3</sub> 52, NaClO<sub>3</sub> 51, NaCl 48, NaC<sub>2</sub>H<sub>3</sub>O<sub>2</sub> 47, Na<sub>2</sub>SO<sub>4</sub> 46, Na citrate 46, H<sub>2</sub>O 45%.  $p_H$  values of these solns. all lay between 5.2 and 7.2, and there was no relation between,  $p_H$  value and degree of swelling. High concns. of NaSCN at high temps. peptize wool giving strongly fluorescent solns. The acid-alkali swelling curve of wool was obtained with solns. of NaOH and HCl, free from salts. The curve shows a sharp min. at  $p_H$  0, a sharp max. at  $p_H$  1.25, a broad min. at  $p_H$  3.75-5.25, apparent inflection point at  $p_H$  8. Deaminized wool, and wool treated with quinine, swell less than ordinary wool in  $p_H$  range 0.5-3, and the isoelec. point is displaced toward  $p_H$  3. Irradiated wool swells more at all  $p_H$  values than ordinary wool; the isoelec. point is unchanged. In solns. of H<sub>2</sub>S, wool swells less than in pure H<sub>2</sub>O, but wool pretreated with H<sub>2</sub>S swells more in alk. soln. than does wool not pretreated. This supports the hypothesis that SH<sup>-</sup> renders keratin more reactive toward OH<sup>-</sup>. Determination of NH<sub>2</sub> groups in wool.—The app. consists of (1) source of CO<sub>2</sub> and purification train, (2) reaction vessel, consisting of glass-stoppered flask provided with gas inlet and outlet, and stop-cock thistle tube for introducing acid, (3) absorption bottle contg. a soln. of 20% NaOH and 6% KMnO<sub>4</sub>, and (4) gas-measuring tube (1 g. wool is placed in the reaction flask). The app. is freed from air by CO<sub>2</sub> current. A mixt. of 20 cc. of 10% nitrite soln. and 15 cc. glacial AcOH is introduced through a stopcock funnel. Reaction begins immediately.

$\text{NO}_2$  and  $\text{N}_2$  are evolved and entrained by  $\text{CO}_2$  current.  $\text{CO}_2$  and  $\text{NO}_2$  are absorbed by alk.  $\text{KMnO}_4$ .  $\text{N}_2$  is collected and measured. A sample of raw, degreased wool gave 0.57%  $\text{N}_2$ . Chem. treatment that tends to hydrolyze wool increases the yield of amino N. Silk fibroin gave only 0.40%  $\text{N}_2$ , which indicates fewer amino groups than in wool; this is in line with the greater swelling of the latter. H. B. MERRILL.

Some scientific aspects of wool as they affect the wearer. S. G. BARKER. *J. Soc. Dyers Colourists* 45, 77-82(1929).—Detns. of fiber shape, density, moisture absorption, tensile strength, elasticity, plasticity, and ultra-violet transmission of wool are reviewed and their value to the finished fabric is discussed. Tables and references are given.

T. G. HAWLEY, JR.  
Some points in scouring woollens and worsteds. ALEX. J. BENNETT. *Textile Colorist* 51, 394-6(1929).

Emulsions, their scope and application (BILLINGHAM) 13. Constitutional influences on the conversion of azonaphthols into their azosulfites and their bearing on the structure of  $\alpha$ - and  $\beta$ -naphthol (KING) 10. Emulsions for use as detergents in dyeing, etc. (Brit. pat. 299,817) 18.

*Handbuch des Zeugdrucks*. Lfg. 3. Edited by Georg Georgievics, Robert Haller and L. Lichtenstein. Leipzig: Akad. Verlag. pp. 513-801. M. 32. Cf. C. A. 22, 3534.

Dyes. L. B. HOLLIDAY AND CO., LTD., JOE KITSON and CECIL SHAW. Fr. 651,731, Mar. 24, 1928. See Brit. 293, 110 (C. A. 23, 1511).

Dyes. I. G. FARBENIND. A.-G. Brit. 299,909 Aug. 4, 1927. Sulfuretted dyes are obtained by polysulfide fusion, in the presence of  $\text{CuSO}_4$ , of indophenols produced by joint oxidation of *p*-aminophenol and alkyl ethers of *p*-hydroxyaryl-1-naphthyl-aminomonosulfonic acids or of the corresponding leuco indophenols. The dyes formed dye cotton clear, fast, greenish yellow tints from a Na sulfide bath. Several examples are given.

Dyes. I. G. FARBENIND. A.-G. Brit. 300,114, Nov. 5, 1927. A deriv. of 3-hydroxy-1-thionaphthene substituted in the nucleus is condensed with 7-methylisatin  $\alpha$ -chloride substituted by halogen or methyl in the 5-position or by halogen or methyl (or both) in the 4- and 5-positions. Several examples are given.

Dyes. I. G. FARBENIND. A.-G. Brit. 300,219, July 7, 1927. Anthraquinone vat dyes are formed by heating anthrones having a further ring attached in the *ms*- and 1-positions (at least in the latter by means of a N atom) and halogenated in the 2-position, with metals, with or without use of a solvent. Various details and examples are given.

Dyes. I. G. FARBENIND. A.-G. Fr. 652,080, April 2, 1928. Dyes which dye silk and cotton mordanted with tannic acid are prepd. by reacting diazo compds. of safranin with  $\beta$ -diketones. Thus, tolusafranin is diazotized and coupled with acetylacetone, acetoacetic ester, malonic ethyl ester, acetoacetic-*o*-toluidide, or acetoacetic xylidide forming dyes which give Bordeaux-red shades. Diethylsafranin is diazotized and coupled with acetoacetic anilide, acetoacetic ester, methylacetoacetic ester, malonic ethyl ester, acetylacetone, benzoylacetone, etc., giving dark blue and green shades.

Dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Brit. 299,791, Oct. 31, 1927. Direct dyes for cotton are made by coupling a diazo compd. of the benzene or naphthalene series with a further diazotizable component of the benzene or naphthalene series, rediazotizing, and coupling with 1,5,7-aminonaphtholsulfonic acid in an acid, neutral or alk. medium. The products give uniform gray to blue-gray and green-gray dyeing from neutral or slightly alk. baths. Several examples are given with a statement of the properties of the dyes produced.

Azo dyes. I. G. FARBENIND. A.-G. Fr. 651,945, Mar. 29, 1928. Azo dyes are produced in substance or on the fiber by coupling with an arylamide of 2,3-hydroxynaphthoic acid the diazo compd. of a dihalogen deriv. of *p*-toluidine having a halogen atom *o*- and *m*- to the  $\text{CH}_3$  group. Several examples are given and also a list of components and colors obtained.

Azo dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Brit. 299,331, Oct. 22, 1927. Azo dyes and intermediate products contg. at least one cyanuric ring and at least one thiazole ring are obtained either (1) by condensing a cyanuric halide with suitable compds. at least one of which contains a thiazole ring and, if necessary, converting the product into an azo dye by diazotization and coupling or by coupling with a diazo compd., or (2) by coupling a diazo component with a coupling component and for

this purpose selecting components one of which contains a cyanuric ring and the other of which contains a thiazole ring. The dyes thus formed may be subjected, either in substance or on the fiber, to addnl. treatments such as reduction, condensation, acidylation (such as treatment with phosgene), alkylation, aralkylation, arylation, further coupling with a diazo compd., diazotization and further coupling with a component, or treatment with a metal compd. A very large number of examples are given.

**Azo dye formed by combining diazotized aromatic amino-pseudoazimino compounds with arylides of 2,3-hydroxynaphthoic acid.** AUGUST L. LASKA and ARTHUR ZIRTSCHER (to I. G. Farbenind. A.-G.). U. S. reissue 17,306, May 28. Reissue of original pat. No. 1,667,667 (C. A. 22, 2065).

**Vat dyes.** ALBERT KUNZ and KARL KÖBERLE (to Grasselli Dyestuff Corp.). U. S. 1,714,427, May 21. A *ms*-benzodianthrone is halogenated at atm. pressure, e. g., with Br in  $\text{PhNO}_2$  with or without I, which forms a dye giving yellow shades on cotton.

**Vat dyes.** I. G. FARBENIND. A.-G. Fr. 652,002, Mar. 30, 1928. Vat dyes are prepd. by transforming a 3-methyl-4-halophenyl-1-thioglycolic acid, substituted in the 2-position by a carboxy, carbamyl or nitrile group, into the corresponding hydroxythionaphthenes and converting the latter by oxidation into sym. thioindigo dyes, or by condensing the said hydroxythionaphthenes or their 2-derivs. with a compd. capable of coupling therewith. In examples, the nitrile of 3-methyl-4-chlorophenyl-1-thioglycolic-2-carboxylic acid is heated with NaOH and  $\text{Na}_2\text{S}$  in water, the Na salt of 4-methyl-5-chloro-3-amino-1-thionaphthene-2-carboxylic acid being pptd. on addn. of NaCl. The ppt. is dissolved in water contg. a small quantity of NaOH and bisulfite acidified with  $\text{H}_2\text{SO}_4$  and heated until the hydroxythionaphthene is formed, and transformed to a dye by known methods. The 4,4'-dimethyl-5,5'-dichlorobisthionaphthene-indigo gives fast violet-red shades on cotton. 3-Methyl-4-chlorophenyl-1-thioglycolic-2-carboxylic acid is heated to boiling with  $\text{Ac}_2\text{O}$  and  $\text{AcONa}$ , and the 4-methyl-5-chloro-3-acetylhydroxythionaphthene is sapond. and oxidized to form the dye. Chloroisatin is heated in  $\text{C}_6\text{H}_6$  with  $\text{PCl}_5$  and 5-bromo-4-methyl-3-hydroxythionaphthene is added; the dye obtained dyes cotton in a bluish violet shade.

**Vat dyes.** I. G. FARBENIND. A.-G. Fr. 652,359, April 7, 1928. Vat dyes of the anthanthrone series are prepd. by heating with condensing agents such as  $\text{H}_2\text{SO}_4$ ,  $\text{ClHSO}_3$ ,  $\text{AlCl}_3$ , KOH, etc., the dyes obtained by condensing halogenated anthantrones with aminoanthraquinones and oxidizing if necessary. Examples are given.

**Vat dyes.** I. G. FARBENIND. A.-G. Fr. 652,388, April 7, 1928. Vat dyes are prepd. by transforming 3,5,6-trimethylbenzene-1-thioglycolic acid, or one of its substitution products contg. a carboxyl, carbamyl or nitrile group in the 2-position, into the corresponding hydroxythionaphthene and converting the latter by oxidation into the 4,6,7,4',6',7'-hexamethylbisthionaphtheneindigo, or condensing the hydroxythionaphthene with a compd. capable of coupling with it. An example is given of the conversion of the nitrile of 3,5,6-trimethylbenzene-1-thioglycolic-2-carboxylic acid, by heating it with aq. NaOH, into 4,6,7-trimethyl-3-amino-1-thionaphthene-2-carboxylic acid which is converted to the dye in known manner. The nitrile used may be prepd. by replacing the  $\text{NH}_2$  of 1-amino-2-nitro-3,4,6-trimethylbenzene by CN, reducing the  $\text{NO}_2$  group to  $\text{NH}_2$  and replacing this by  $\text{SCH}_2\text{COOH}$  in known manner.

**Reducing vat dyes, etc.** I. G. FARBENIND. A.-G. Brit. 299,899, May 4, 1927. Reduction products of vat dyes or of other org. substances contg. reducible carbonyl or quinone groups are obtained by treating the substances with mixts. of  $\text{SO}_2$  and formic acid, in the free state or partly in the form of salts, in the presence of an org. base such as pyridine and in the absence of any considerable quantity of water. Examples are given of the reduction of indigo and several of its derivs. and of the reduction of isatin to .dioxindole.

**Anthraquinone vat dyes.** I. G. FARBENIND. A.-G. Brit. 299,972, Sept. 30, 1927. Vat dyes are obtained by alk. condensation of the  $\alpha,\beta$ -di-9-anthronyleneethylenes obtainable by condensation of an anthrone 2 and glyoxal 1 mol. as described in Brit. 296,817 (C. A. 23, 2578). Examples are given for producing claret-red dyes.

**Green vat dye.** BERTHOLD STEIN, WILLY TRAUTNER and ROBERT BERLINER (to Grasselli Dyestuff Corp.). U. S. 1,713,680, May 21. 10,10'-Diphenylviolanthrone is formed by alkali fusion and oxidation, from 10-phenylbenzanthrone. It forms a blue vat from which cotton is dyed bluish green shades of good fastness.

**Acid wool dyes.** I. G. FARBENIND. A.-G. Brit. 299,721, Oct. 29, 1927. Acid wool dyes are formed by causing a sulfonic, nitrosulfonic, aminosulfonic or sulfamic acid of naphthalic anhydride to react with  $\text{NH}_3$  or an aliphatic or aromatic amine. Similar or identical dyes are also obtainable by converting the products of the reaction

of naphthalic anhydride or its derivs. with  $\text{NH}_3$  or an aliphatic or aromatic amine into the sulfonic or sulfamic acid, or by treating naphthalic anhydride or its derivs. with sulfonated amines. Several examples are given of dyes producing yellow or orange colored dyeings on animal fiber.

**Safranine dyes.** I. G. FARBENIND. A.-G. Brit. 300,178, Nov. 7, 1927. Dyes giving blue to violet shades on wool from an acid bath are prepd. by oxidation of a 4-acidylamino-3'-amino- or 4-nitro-3'-aminodiphenylaminesulfonic acid or a homolog or deriv. with a *p*-phenylenediamine or a deriv. The acidylamino group in the product may be saponified and the nitro groups may be reduced, *e. g.*, by use of Zn and HOAc or by alk. hyposulfite, and the resulting leuco compd. then oxidized. Several examples are given.

**Dyes of the pyrone series.** MAX WEILER (to Grasselli Dyestuff Corp.). U. S. 1,715,261, May 28. In order to remove by-products (which cause dulling and discoloration of dyeings) from dyes formed as described in U. S. 1,532,790 (C. A. 20, 509), the by-products (usually of browner color than the desired products) and desired dye acids in mixt. are converted into salts such as Na salts and the difficultly sol. salts of the pure pyrone dyes are sepd. from the more readily sol. salts of the by-products. Examples are given.

**Dye comprising a mixture of isoviolanthrone and dichloroisoviolanthrone.** BERTRAM MAYER and HUGO SIEBENBÜRGER (to Soc. anon. pour l'ind. chim. à Bâle). U. S. 1,715,242, May 28. A dye of this compn. produces vivid violet dyeings.

**Cinnamylideneanthrones.** ROBERT BERLINER, BERTHOLD STEIN and WILLY TRAUTNER (to Grasselli Dyestuff Corp.). U. S. 1,713,590, May 21. Cinnamylideneanthrone (probably a 10-deriv.), a yellow cryst. substance m. after crystn. from acetone at  $110^\circ$ , sol. in concd.  $\text{H}_2\text{SO}_4$  with a cornflower-blue color, which turns bluish red and after some standing shows a green fluorescence, is formed by the condensation, in a neutral or acid medium, of cinnamaldehyde and anthrone. Substituted anthrones such as  $\alpha$ - and  $\beta$ -hydroxyanthrones,  $\alpha$ - and  $\beta$ -chloroanthrones, anthrone- $\beta$ -carboxylic acid, alkyl and arylanthrones, etc., and substituted cinnamaldehydes and their derivs. react similarly. The products may be used as *dye intermediates*.

**1,4-Diarylamino-5,8-dihydroxyanthraquinones.** KLAUS WEINAND (to Grasselli Dyestuff Corp.). U. S. 1,713,576, May 21. Leuco-1,4,5,8-tetrahydroxyanthraquinone is heated under practically anhyd. conditions with an arylamine (suitably *p*-toluidine for the production of 1,4-di-*p*-toluino-5,8-dihydroxyanthraquinone) in the presence of arsenic acid and a condensing agent such as boric acid. The products may be used as *dye intermediates*.

**Phthaloyl-2,3-thionaphthenes.** FRITZ MAYER (to Grasselli Dyestuff Corp.). U. S. 1,713,670, May 21. Phthaloyl-2,3-thionaphthene and its substitution products can be obtained by causing phthalic anhydride or a substitution product to act upon thionaphthene or a deriv. and condensing the thionaphthenylbenzoic acids thus formed. The products may be used as *dye intermediates*. Phthaloyl-2,3-thionaphthene, corresponding most probably to the formula:

is a yellow powder which is insol. in water, alkalies and acids and yields with alk. hyposulfite a feebly colored vat which dyes wool yellow tints.

**Lakes.** I. G. FARBENIND. A.-G. Brit. 299,521, July 28, 1927. In a process generally similar to that described in Brit. 275,943 (C. A. 22, 2471), there are employed as starting materials mixts. of the specified amines with basic dyes, which may or may not contain acid groups. Examples are given of the treatment, with Na phosphotungstate, of (a) 4,4'-tetramethyldiaminobenzohydrol and Victoria pure blue BO; (b) 4,4'-tetramethyldiaminobenzohydrol and light green SF; and (c) *p*-aminobenzaldehyde and Victoria pure blue BO; which form, resp., deep blue, greenish blue and olive-green products. Cf. C. A. 23, 1283.

**Dyeing fatty acids.** I. G. FARBENIND. A.-G. Brit. 299,790, Oct. 31, 1927. Materials such as stearic acids or other "higher fatty acids" or their mixts. with ceresin,

paraffin, etc., are treated with an org. deriv. of  $\text{NH}_3$  before, during or after dyeing or coloring with org. or inorg. substances. Alkyl-, aryl-, and aralkylamines, and especially hydroxyalkylamines, are suitable, and various coloring substances may be used. Numerous examples are given.

**Dyeing textiles.** SOC. ANON. POUR L'IND. CHIM. À BALE. Fr. 651,810, Mar. 27, 1928. In dyeing dense textiles the textiles are first treated at a high temp. with protective colloids such as glue and waste sulfite cellulose lye, and then dyed without rinsing in the presence of glue or waste sulfite cellulose lye.

**Dyeing material on dipping frames.** I. G. FARBERIND. A.-G. Brit. 299,743, July 26, 1927. Dyeing with ester compds. of leuco indigo and other leuco vat dyes is effected with a bath to which starch, glue, dextrin or the like is added to reduce the mobility of the ester compd. on the material and thus ensure a more even drying of the stretched material. Details of procedure are given.

**Dyeing mixed fabrics containing "acetate silk."** I. G. FARBERIND. A.-G. Brit. 299,787, Oct. 31, 1927. Compns. suitable for dyeing materials contg. both "acetate silk" and other fibers such as wool, cotton, or natural silk comprise a diazotizable base suitable for dyeing the "acetate silk," a cotton or wool dye and a wetting agent. Examples are given.

**Dyeing fur.** VASILY E. BOLDIREV and PETER N. KORUKIN (one-half to Peter F. Naletko and Feodor M. Chalov). U. S. 1,714,941, May 28. The fur is tumbled with a mixt. of dry coloring matter and sawdust until it has acquired the desired color.

**Printing cloth.** I. G. FARBERIND. A.-G. Fr. 652,596, April 12, 1928. In printing cloth with dyes which require alkali for their fixation on the fiber, the dyes contg. vegetable mucilages coagulable by alkalies or other basic agents are printed on the cloth, which is then passed through an alk. bath contg. a reducing agent. Cf. C. A. 23, 1759.

**Printing or stenciling cellulose derivatives.** HENRY DREYFUS. Fr. 651,934, Mar. 29, 1928. Cellulose derivs., particularly the acetate, are printed or stenciled by the application of pastes or aq. dispersions of dyes or insol. or relatively insol. compds. in a non-dispersed form. The material may be treated with Al acetate before printing.

**Printing or stenciling cellulose esters or ethers.** H. PLATT (to British Celanese, Ltd.). Brit. 299,849, Nov. 2, 1927. To facilitate obtainment of sharply defined outlines, the materials are treated, before application of dyes, with a basic metallic acetate such as that of Al to which is also preferably added an org. acid such as  $\text{HOAc}$  or formic acid. Examples with details of the treatment are given.

**Dyeing apparatus.** THE DELTEX CO. Fr. 651,717, Mar. 24, 1928.

**Vat and circulating system for dyeing or washing textile materials.** CECIL F. HAMMOND and WILLIAM SHACKLETON. U. S. 1,714,777, May 28. Structural features.

**Spinnable fiber from coconut husks.** BAREND G. H. VAN DER JAGT (one-third each to Dr. Zadok van der Bergh and Frederick A. J. van Kuyk). U. S. 1,713,681, May 21. Husks are sepd. from the shell, crushed to facilitate access of liquid into the matted mass of fiber and the material is satd. with a liquid such as a boiling weak alkali soln. which facilitates slipping of the fibers one over another, surplus soln. is pressed out and the satd. husk is repeatedly treated to effect disintegration and alternately pressed between rollers; the fiber and pith are subjected to differential drying to enable removal of the pith, thus leaving a sepd., clean spinnable fiber suitable for making woven fabrics.

**Drying and carbonizing webs of fabric.** JOSEPH H. WALSH (to Johns-Manville, Inc.). U. S. 1,714,062, May 21. The fabric is subjected to successive treatment with radiant heat and highly heated still air while passing through an app., which is described, in a series of vertical runs over guide rollers.

**Mercerizing cotton.** OTTO DUBAC. Fr. 33,797, June 25, 1927. Addn. to 618,170. Linen and silk effects are obtained by treating cotton alternately in hot and cold baths contg.  $\text{NaOH}$  for a short time, the cotton being washed out with boiling water after each treatment.

**Dissolving natural silk.** TOMENOSUKE MUTO and SABURO HIDA (to Kanega-Fuchi Boseki Kabushiki Kwaisha). U. S. 1,714,039, May 21. See Fr. 649,979 (C. A. 23, 3111).

**Artificial silk of the hollow-filament type.** ALSA SOC. ANON. Brit. 299,710, Oct. 29, 1927. Hollow filaments are further distended during the process of coagulation or subsequently, by immersion in a liquid contg. a gas in soln. or a gas-generating material and then subjecting the material to treatment such as heating or reduction of pressure or chem. treatment to cause generation of gas; e. g., a hollow filament of "viscose silk" is immersed in cold water satd. with air and the temp. then raised; or a hollow filament

may be soaked in  $\text{Na}_2\text{CO}_3$  soln. and then treated with dil.  $\text{HOAc}$  preferably satd. with air or  $\text{CO}_2$ . The product is preferably dried in closed chambers at  $80\text{--}100^\circ$ .

**Treating artificial silk.** I. G. FARBERIND. A.-G. Fr. 651,770, Mar. 26, 1928. The bobbins on which the artificial silk is wound are magnetic, and are put in and out of the various washing and treating baths by electromagnetic means.

**Gas-proof cloth.** L'ÉTAT FRANÇAIS (REPRÉSENTE PAR LE MINISTRE DE LA GUERRE). Fr. 652,150, Nov. 24, 1926. Cloth which is supple and impermeable to gas has a coating of cellulose covered by a coating of varnish having a basis of cellulose ester.

**Treating surfaces of hat bodies.** VICTOR BÖHM. U. S. 1,713,641, May 21. A neutral reagent contg. a carbonyl group such as  $\text{CH}_2\text{O}$  or other aldehyde or ketone is applied to the surface of hair or wool hat bodies, in order to improve their gloss or smoothness. An oxidizing agent is also preferably used.

**Apparatus for preparing bleaching solutions for laundry use, etc.** GEORGE M. HOGAN. U. S. 1,713,657, May 21.

## 26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

**Reflection factors of white paint.** F. H. RHODES AND J. V. STARR. *Ind. Eng. Chem.* 21, 596-9 (1929).—The effects of the addn. of known amts. of C black, Prussian blue, and Al powder upon the brightness and the hiding power of white paints are measured in a reflectometer. Small quantities of C black or of Prussian blue decrease the brightness only slightly and increase the hiding power markedly. With larger amts. of the colored pigments the decrease in the brightness becomes relatively more pronounced. With very small quantities of Prussian blue the ratio of the increase in hiding power to the decrease in brightness is greater than with C black. The addn. of Al powder greatly increases the hiding power, but lowers the brightness and causes the dry film to have a flecked appearance. The use of Al powder in undercoats for white finishing coats is of advantage.

R. J. MOORE

**The influence of light on paints containing lead.** I. G. ZEIDLER AND W. TOELDT. *Farben-Ztg.* 33, 2607-11 (1928).—Eleven paints contg. various Pb pigments in whole or in part were spread on Fe panels and exposed to the radiations from the sun, an arc light, a mercury arc and a Nitra lamp for intervals from 6 to 28 hrs. The degree of darkening or lightening and loss of gloss was compared with a set kept in the dark. The results are shown in graphs which should be consulted for the details. II. *Ibid* 34, 1547-9 (1929).—Films of the paints described in I were exposed to dil.  $\text{H}_2\text{S}$  fumes for 15 min. and then to the various light sources for periods of 1 to 3 hrs. In general, the mercury arc effected the greatest degree of fading of the discoloration produced by the  $\text{H}_2\text{S}$ , but the relative effects of the different radiations on the various paints were not uniform.

**British standard specification for oil pastes (colored) for paints.** *Brit. Eng. Standards Assoc.* No. 390, 7 pp. (1929).

E. I. S.

**British standard specification for tinted oil pastes for paints.** *Brit. Eng. Standards Assoc.* No. 393, 9 pp. (1929).

E. I. S.

**Spray painting.** LEONARD GREENBURG. *New Haven Health Dept.* 55, No. 10, 3-4 (1928); *U. S. Pub. Health Eng. Abstracts* E-789c, 4.—The spraying of lacquers with paint spray guns was investigated. When paints contg. Pb or benzene are applied with a spray gun, the painter should be protected by means of masks or respirators and suitable exhaust ventilation. Efforts are being made by the Natl. Safety Council to produce non-injurious painting materials.

C. R. FELLERS

**Casein paints.** F. MARGIVAL. *Peintures, pigments, vernis* 5, 673-5 (1928).—Various compns. of casein-contg. paints are given.

B. HAMILTON

**The red lead question.** A. JUNK. *Farben-Ztg.* 34, 1664-7 (1929); cf. C. A. 23, 1291.—Reply to criticisms by Wolff, Toeldte and Zeidler (C. A. 23, 2839) and by Luty.

G. G. SWARD

**Oil absorption of pigments.** RUCHTI. *Farben-Ztg.* 34, 1954 (1929).—The oil absorption of a pigment depends upon the compn. as well as the degree of subdivision.

*E. g.*, 3 others characterized by oil absorption values (according to the method of Wolff, Zeidler and Toeldte, *Farben-Ztg.* 33, 2730(1928)) of 39, 33 and 33 possessed relative finenesses of 2, 11 and 3, resp. No. 1 contained much clay and no. 2 much lime. Any method which is capable of reasonable precision is satisfactory even though the values are not minimum ones.

G. G. SWARD

**The resistance to light of typed manuscripts, their carbon copies and writing made with copying ink pencils.** H. I. WATERMAN, J. GROOT AND M. J. TUSSENBOECK. *Chem. Weekblad* 26, 276-7(1929).—Writing obtained with violet typewriter ribbon (methyl violet and carbon black as coloring matter) and with black carbon paper faded slightly after 3 weeks' exposure to daylight. Copies made with violet carbon paper contg. only methyl violet faded strongly or entirely. Conclusion: The use of typewriter ribbons and carbon papers contg. carbon black furnishes manuscripts suitable for archive purposes. Violet carbon paper and copying ink pencil contg. only methyl violet as coloring matter are unsuitable for copies which are to be kept for long periods.

F. DE LEEUW

**Physico-chemical studies on the mechanism of the drying of linseed oil. I. Changes in density of films.** G. L. CLARK AND H. L. TSCHENTKE. *Ind. Eng. Chem.* 21, 621-7(1929).—Accurate density measurements were made by the flotation method on a large no. of thin, baked films of linseed oil. These films and the characteristic density changes (usually increasing) illustrate the effects of drier, sunning and weathering, ultra-violet exposure, ozonization, natural aging in darkness, influenced of thickness, effect of 2 films superposed, metallic soaps and inhibitors. A mechanism of failure of linseed oil films independent of complex chem. changes is indicated by the density data: stresses and strains are set up throughout the film as a result of unequal contraction of surface and inner layers. Also crystn. of metallic soaps causes non-homogeneity and failure.

R. J. MOORE

**Effect of various driers on linseed oil films during aging.** P. E. MARLING. *Ind. Eng. Chem.* 21, 594-6(1929).—This is a continuation of previously reported expts. (*C. A.* 21, 658, 1889). It shows the relationship during aging of acid no., I no., and soly. of linseed oil films contg. different concns. of Pb, Mn and Co.

R. J. M.

**British standard specification for tung oil.** *Brit. Eng. Standards Assoc.* No. 391, 9 pp.(1929).

E. I. S.

**Non-scaling (aqueous) vehicles.** A. CHRIST. *Farbe u. Lack* 1929, 218.—Scaling of distempers occurs whenever the surfaces to which they are applied possess less tensile strength than the dried films. Succeeding coats should therefore be formulated with progressively less glue than the preceding ones. Weak plaster walls also tend to allow scaling of distempers.

G. G. SWARD

**Place of synthetic amyl products among lacquer solvents.** M. M. WILSON AND F. J. WORSTER. *Ind. Eng. Chem.* 21, 592-4(1929). Recent addns. to the present group of lacquer solvents are synthetic Am alc. and synthetic Am acetate. This alc is made from pentane as a raw material. The synthetic Am alc. is practically a duplicate of the so-called high-test fusel oil offered in the past. The synthetic Am acetate is prepd. from the alc. and AcOH. In lacquer formulation this acetate ranks in the general class of high boilers, including Bu propionate, fusel oil acetate, Cellosolve acetate, etc. Lab. data are given showing various relations between these and other solvents. These comparisons are based on the usual methods of testing the suitability of solvents, and consist of data on distn., tolerance of nitrocellulose solns. for hydrocarbons, viscosities of nitrocellulose solns., evapn. rates and soly. of resins.

R. J. M.

**New materials for the lacquer industry.** AUGUST NOLL. *Farben-Ztg.* 34, 1486-90, 1549-52(1929).—A review of the phys. properties of recently developed lacquer solvents, plasticizers and diluents which are in use in Germany. Many of them are described under their trade names.

G. G. SWARD

**Zinc compounds in nitrocellulose lacquers.** WALTER BAER. *Chem.-tech. Rundschau* 44, 51(1929).—Nitrocellulose contg. 11.8-12.3% N is used in the production of nitrocellulose lacquers. These are colored chiefly with mineral pigments, brightened sometimes with 2-6% of an org. dyestuff. Zn compds. such as zinc white, zinc sulfide and lithopone are particularly suitable as pigments. The first of these stabilizes the film. Lacquers contg. lithopone do not withstand weathering. A mixt. of lithopone and Zn sulfide is stable and has very good covering power. In these lacquers easily hydrolyzable compds. such as ethyl acetate should be avoided. In zinc enamels dibutyl phthalate is a suitable plasticizer, but tricresyl phosphate is not since it yellows the Zn pigments.

E. PICKERING

**Brief notes on crystallizing lacquers and toluene resins.** H. A. GARDNER. *Am. Paint and Varnish Mfrs. Assoc. Sci. Sect. Circ.* No. 348, 321-31(1929).—References

are quoted describing various types of crystal, crackle and wrinkle finishes. Notes are given on producing some of these finishes. One of the cryst. lacquers is produced by pptn. of a toluene-formaldehyde condensation resin in a lacquer film. Properties of this resin are described. Photomicrographs are shown of crystg. lacquers.

R. J. MOORE

**Recent results from the investigations of resins.** W. NAGEL. *Metallbörse* 19, 173-4 (1929).—Because resins afford substances closely related to one another, easily undergoing transformations into similar compds., their study is difficult. While colophonium is derived from a methylpropylphenanthrene nucleus, shellac is  $\text{CH}_2\text{OH}-(\text{CH}_2)_3-(\text{CHOH})_2-(\text{CH}_2)_7-\text{COOH}$ . Less definite information is available concerning other natural resins. The synthetic resins are becoming of so much greater importance than the natural resins that studies of the compn. of the latter substances have little practical value.

W. C. EBAUGH

**Hardening and esterification of rosin.** A. I. GELIKH. *J. Chem. Ind. (Moscow)* 6, 253 (1929); cf. C. A. 22, 3055.—Pyhäälä's calcns. are based on the supposition that rosin consists of abietic acid only; in reality it may consist of abietic anhydride and it may contain other resinous substances. If rosin consisted of abietic acid only, 200 parts of it would have to be melted with 60.6 parts  $\text{C}_3\text{H}_5(\text{OH})\cdot\text{CaO}$ , and not with 27 parts, as Pyhäälä prescribes. As a whole, the mechanism of this reaction, as well as those of the other reactions given by Pyhäälä, is not clear. In reality the monoglycerinate,  $\text{MnO}(\text{OH})_2\cdot\text{C}_3\text{H}_5$ , is not obtained in any of the known reactions, but the diglycerinate can be obtained from  $\text{C}_3\text{H}_5(\text{OH})_3$ ,  $\text{NaOH}$  and  $\text{MnO}_2$ . The other reactions given by Pyhäälä are also incorrect.

BERNARD NELSON

**Advances in the production of artificial resins.** W. BAER. *Chem.-tech. Rundschau* 44, 208 (1929).—A brief and incomplete review.

E. PICKERING

**Euphorbone from euphorbium resin (MÜLLER) 10.** Present status of the chemistry of the resinic acids of conifers (LÉVY) 10. Our knowledge of resinic acids (ROUIN) 10. Retene and some of its derivatives (LI MAN CHEUNG) 10.

**Paint.** HERMANN FRENKEL. Fr. 651,771, Mar. 26, 1928. A paint, several coats of which may be applied without drying, has a binder of fatty oil with which  $\text{SCl}_2$  is caused to react partially while diluents and more fatty oil are added. The paint used for the first coats may have added high b. p. hydrocarbons or esters, essential oils or amines to prevent rapid drying on the surface.

**Paint.** DEUTSCHE GASGLÜHLICHT AUER-G. M. B. H. Fr. 652,322, April 6, 1928. The resistance of paints, particularly oil paints, to the weather is increased by the addn. of insol. germicides, such as compds. of Cu, Zn, Cd, Hg or poisonous org. compds.

**Titanium pigments.** F. G. C. STEPHENS, L. J. ANDERSON and W. A. CASH. Brit. 299,835, Aug. 2, 1927. A Ti sulfate soln. is added gradually to a prepd. bulk of a soln. of a sol. alk. earth metal salt such as  $\text{BaCl}_2$ , and a temp. of 30-35° is suitable during the pptn. of the alk. earth metal sulfate, with a subsequent heating at about 100° to ppt. substantially all the Ti from the soln. Various details are given. Cf. C. A. 22, 1862.

**Pigments containing titanium.** FRANCIS G. C. STEPHENS, LENNOX J. ANDERSON and WILLIAM A. CASH (to National Metal and Chemical Bank, Ltd., of London, England). U. S. 1,714,408, May 21. See Brit. 273,017 (C. A. 22, 1862).

**Zinc and cadmium sulfide pigments.** L. A. LEVY and D. W. WEST. Brit. 299,797, July 1, 1927. Phosphorescent and fluorescent Zn or Zn-Cd sulfides for use as pigments are treated after firing with a soln. of alkali metal phosphate (preferably  $\text{Na}_3\text{PO}_4$ ) or carbonate or borax and the solvent is evapd. White metal oxides such as those of Mg, Th, Al or Ce or other rare earth or alk. earths are also preferably added.

**Ultramarine.** B. K. KLIMOV. Russ. 5542, June 30, 1928. Instead of tar and the siliceous materials that are the usual ingredients of the ultramarine mixture, oil shale is used. The mixt. is heated and the product then treated in the usual way.

**Printing ink suitable for use on rubber.** HERBERT N. MORRIS. U. S. 1,715,209, May 28. An ink suitable for use on rubber, celluloid, etc., contains acetone, tetrahydronaphthalene, methylethyleneglycol and spirit-sol. induline.

**Lithographing ink.** OTTO E. HARDER. U. S. 1,714,166, May 21. A compn. for use with printer's ink comprises "petrolatum oil" 73%, paraffin 21%,  $\text{MgCO}_3$  3% and oleic acid 3%.

**Staining wood.** HAROLD P. VANNAH and JOHN G. GOSSELINK (to Brown Co.). U. S. 1,714,701, May 28. Wood is first impregnated by suction with an acid soln. of

2,4-diaminophenol-HCl or other org. dye intermediate capable of pptg. pigments when neutral or alk., by oxidation, and is then treated with aq.  $\text{NH}_3$  to permit such oxidation in the wood. Cf. C. A. 22, 3756.

**Varnish.** GASTON ROELANDTS. Fr. 652,410, April 10, 1928. A varnish is made by adding Venice turpentine 25, tricresyl phosphate 10, BuOH 10, linseed oil 3, to 100 parts of collodion made from nitrocellulose 30, AcOBu 45, toluene 18 and EtOH 7 parts. This varnish is quickly polished by a mixt. of equal parts of AcOBu, BuOH, vaseline oil and tinct. of benzoin with or without gum lac varnish.

**Plastic substances, varnishes, etc.** I. G. FARBERIND. A.-G. Fr. 651,870, Mar. 29, 1928. Plastic substances, varnishes, etc., having a basis of nitrocellulose are prep'd. by using as gelatinizing agents esters of phthalic acid in which a carboxylic group is esterified by the radical of an aromatic or hydroaromatic alc., and finally adding resins, fillers, dyes, solvents, etc. Examples are given.

**Nitrocellulose varnishes.** I. G. FARBERIND. A.-G. Fr. 652,658, April 13, 1928. See Brit. 289,387 (C. A. 23, 703).

**Coating compositions.** W. H. MOSS (to British Celanese, Ltd.). Brit. 299,781, Oct. 31, 1927. Cellulose derivs. such as the acetate, formate, propionate or butyrate or methyl or ethyl cellulose are used with a ketone-phenol-aldehyde resin and a volatile solvent, with or without natural resins, solvents of high b. p., plasticizers, dyes or pigments. Such compns. may be used as lacquers over a priming coat which may contain linseed oil or over nitrocellulose lacquers, and may be covered with a cellulose acetate lacquer contg. no synthetic resin. Brit. 299,782 relates to solvents for use in such compns. and which comprise a mixt. of  $\text{C}_6\text{H}_6$ , ethylene dichloride and EtOH or a similar mixt. of an aromatic hydrocarbon, a halide of an unsat'd. hydrocarbon and an alc. Various optional ingredients are specified.

**Lacquer.** YVES M. CORTIN. Fr. 649,939, Aug. 4, 1927. An unbreakable lacquer for Fe, wood, etc., contains metallic filings such as Cu dissolved in an acid, with or without ZnO. The linseed oil used is preferably heated first to a high temp., and the proportion of gum is higher than in the usual lacquer.

**Colored lacquers.** HANS WOLFF and RUDOLF SINGER. Fr. 652,441, April 10, 1928. To prevent thickening or gelatinizing of cellulose lacquers contg. Pb pigments, org. compds. having 3 or more C atoms in the mol. and having either a carboxylic or aldehydic group are added thereto, or the salts (Pb, Na, Mg or Mn) thereof which are sol. in the org. solvents for the lacquers. Appropriate compds. are mentioned.

**Cellulose esters for lacquers, etc.** G. SCHNEIDER (to British Celanese, Ltd.). Brit. 300,140, Nov. 5, 1927. Org. esters of cellulose of low viscosity are prep'd. by an esterification process conducted at a temp. not exceeding that at which a substantial degradation of the cellulose takes place, e. g., at a temp. not exceeding about  $55^\circ$  in prep'g. cellulose acetate with the use of  $\text{H}_2\text{SO}_4$  as a catalyst. Numerous details and other examples are given.

**Ether-alcohol esters of polycarboxylic acids such as phthalic acid.** JOHN M. KESSLER and OREGON B. HELFRICH (to Kessler Chemical Co.). U. S. 1,714,173, May 21. Plasticizing agents suitable for use with *pyroxylin lacquers* are produced by bringing an aliphatic ether-alc. as diethylene glycol, triethylene glycol, diethylene glycol Et ether, diethylene glycol Bu ether, dipropylene glycol, ethylene propylene diglycol, etc., or an ether deriv. thereof by substituting a hydrocarbon radical for an H of an OH group, as Et, Pr, Bu, Am, etc., into interaction with a polycarboxylic acid as succinic acid, glutaric acid, maleic acid, phthalic acid, the naphthalenepolycarboxylic acids under conditions such that water is split out and an ester of the carboxylic acid formed. The esterification may be effected by heating the aliphatic ether-alc. and the polycarboxylic acid, preferably in the form of its anhydride. The diethylene glycol Et ether ester of phthalic acid is a neutral viscous liquid having a sp. gr. of 1.1765 at  $20^\circ$  and a flashpoint of  $265-270^\circ$ .

**Artificial horn.** FRANZ PABST. Fr. 652,615, April 12, 1928. A mixt. of phenol, aldol and resin is added to albuminoid material such as casein to be made into artificial horn.

**Treating crude resin.** A. PIETZSCH. Fr. 652,141, April 4, 1928. A small quantity of turpentine oil is added to the crude resin which makes it sufficiently fluid to be filtered in the cold, and it is afterward distd.

**Refining rosin.** IRVIN W. HUMPHREY (to Hercules Powder Co.). U. S. 1,715,083, May 28. See Can. 284,986 (C. A. 23, 1001). U. S. 1,715,086. See Can. 284,988 (C. A. 23, 1001).

**Refining rosin.** HARRY E. KAISER and ROY S. HANCOCK (to Hercules Powder Co.). U. S. 1,715,084, May 28. See Can. 284,985 (C. A. 23, 1001). U. S. 1,715,085

relates to a rosin purified by treatment with furfural. Cf. C. A. 23, 1001. U. S. 1,715,088. See Can. 284,983 (C. A. 23, 1001).

**Refining rosin.** GEORGE M. NORMAN (to Hercules Powder Co.). U. S. 1,715,087, May 28. See Can. 284,984 (C. A. 23, 1001).

**Synthetic resins.** KUNSTHARZFABRIK FRITZ POLLACK G. M. B. H. Fr. 651,723, Mar. 24, 1928. In making artificial resins by condensing phenols and aldehydes, protective colloids such as gum arabic, saponin, casein or gelatin are added to the condensation soln. before or at the moment of the reaction. Preferably neutral salts are added to the soln. before pptn. Cf. C. A. 23, 1294.

**Synthetic resins.** E. I. DU PONT DE NEMOURS & Co. Fr. 652,119, April 3, 1928. Synthetic resins are prepd. by heating a polyhydric alc., e. g., glycerol and a polybasic acid, e. g., phthalic acid, to 180–265° with a drying oil and a natural resin such as Congo resin. The reaction is carried out in a non-reactive atm. such as CO<sub>2</sub> and is continued until the evolution of steam ceases. The resin may be mixed with cellulose esters or drying oils for the production of varnish.

**Synthetic resins.** COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 33,789, June 24, 1927. Addn. to 604,198. Resins which are hardened by heat are solubilized by heating them with a liquid which dissolves the constituent part of the resin, e. g., a glycerol phthalate resin is heated with a solvent for glycerol and phthalic anhydride. A condensation product in the gel state is made sol. by heating it in contact with a liquid in which the product is sol. before being transformed into the gel state.

**Condensation products.** SOC. ANON. POUR L'IND. CHIM. À BÂLE. Swiss 129,592, June 16, 1927. A new condensation product is produced by treating PhNH<sub>2</sub> with C<sub>2</sub>H<sub>2</sub> in presence of a catalyst. The product is a resin which can be used in the varnish and rubber industries. Thus, 280 parts PhNH<sub>2</sub> are stirred with 27 parts HgCl<sub>2</sub> in an atm. of C<sub>2</sub>H<sub>2</sub> at 30–50° until no more C<sub>2</sub>H<sub>2</sub> is absorbed. The product is dissolved in mineral acid and the Hg deposit filtered off. The unchanged PhNH<sub>2</sub> is removed by steam, leaving a reddish resin, m. 70–140°. Other examples are given.

## 27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

**Report on (the analysis of) fats and oils.** G. S. JAMIESON. *J. Assoc. Official Agr. Chem.* 12, 203–5 (1929); cf. C. A. 22, 4000.—Further collaborative work on the Pb salt-Et<sub>2</sub>O method for the detn. of satd. and unsatd. acids confirmed the belief that extensive experience is required on the part of the analyst before the difficult technic can be mastered, but that when the directions are actually followed in every detail as given satisfactory results are obtained.

A. PAPINEAU-COUTURE

**Determination of the saponification number—a more stable alcoholic potash reagent.** D. T. ENGLIS AND V. C. MILLS. *J. Assoc. Official Agr. Chem.* 12, 248–50 (1929).—Addn. of a small quantity of Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub> (5 g. per l.) to alc. KOH reagent was found effective in preventing coloration of the soln. When the clear supernatant liquid is used for the detn. of sapon. values the results obtained with this reagent agree with those obtained with the official reagent. An attempt to find a general inhibitor for color development during the sapon. process was not successful.

A. P.-C.

**Standardization of methods of determination of the iodine number.** J. GIRAL. *Anales soc. españ. fís. quim.* 27, Sección técn., 259–64 (1929).—Unlike other countries, Spain has no official method for detn. of I no. The method used should always be specified in the data.

E. M. SYMMES

**The detection of olive oil in some refined vegetable oils.** W. H. DICKHART. *Olive Oil* 2, 11 (1929); *Squibb Abstract Bull.* 2, A-531.—When 5 cc. of pure olive oil was treated with 5 cc. of a soln. contg. 1 vol. of concd. H<sub>2</sub>SO<sub>4</sub> and 4 vol. of abs. alc. (A), and after the formation of an emulsion 10 drops of a 2% alc. soln. of furfurole (B) added, the lower soln. became dark cherry-red and after standing much darker; refined cottonseed oil failed to give this color even after long heating. Palm-kernel, peanut, coconut, tea-seed and castor oils gave a slight red coloration with this test but on the addn. of 10 cc. of water the color disappeared, leaving a milky soln. Sesame oil gave a pink coloration in the cold but a dark lavender to almost black ppt. in the hot; in the former instance the pink disappeared with the addn. of water. Mustard oil gave a greenish blue and became milky with water. Thus if a pink coloration appears upon the addn. of 5 cc. of A and 10 drops of B to 5 cc. of a sample of oil, sesame oil is indicated;

if after heating on the water bath (94–95°) and adding 10 cc. of cold water a red color appears after 5–10 mins., olive oil is indicated. A very pronounced red coloration with this test on samples of refined cottonseed, soy-bean, peanut, tea-seed, corn oils, etc., contg. 2, 3 and 5% olive oil, is a definite proof of contamination. The test will differentiate between tea-seed oil and olive oil. If sesame oil is present in an oil, olive oil cannot be detected by the above method. H. L. D.

**Fachini's reaction for the identification of oil extracted from the residue from the pressing of olives.** R. MARCILLE. *Ann. fals.* 22, 163–6(1929); cf. Fachini, *C. A.* 21, 3474.—When the reaction is applied to virgin oil contg. a relatively small proportion of extd. oil, it is not very sharp, being masked by the color imparted by the oil to the  $\text{Ac}_2\text{O}$ . This interference can be removed by a preliminary treatment of the oil to be tested with decolorizing black; but a large no. of oils of known purity were found to give a positive reaction after this treatment, such oils generally (but not always) having a high acidity. The reaction is considered as not specific of extd. oils, but is also given by pressed oils obtained from olives which have undergone fermentation. A. P.-C.

**Use of vegetable oils in the soap industry.** S. KAZARNOVSKII AND V. SIZONENKO. *Masloboino Zhirovoe Delo (Oil and Fat Ind. (Russia))* 1928, No. 5, 7–10.—In consequence of a shortage in animal fats and such oils as coconut and palm oil the Russian soap industry is compelled to use liquid vegetable oils which are partly hydrogenated to meet the specifications. The following mixtures are used at the present time. The figures represent for each mixt., resp., the I no. and the percent contents of solid satd. acids, of oleic acid, of linolic acid and of linoleic acid. 70% hydrogenated sunflower oil plus 30% linseed oil 96, 39.9, 37.3, 9.6, 13.2; 70% hydrogenated sunflower oil plus 30% sunflower oil 80, 39.7, 43.5, 16.8, —; 70% hydrogenated sunflower oil plus 30% cottonseed oil 74, 44.6, 47.1, 8.3, —; 70% hydrogenated cottonseed oil plus 30% linseed oil 90, 37.8, 39.4, 9.6, 13.2; 70% hydrogenated cottonseed oil plus 30% sunflower oil 73, 37.6, 45.5, 16.8, —; 70% hydrogenated cottonseed oil plus 30% cottonseed oil 67, 42.5, 49.1, 8.3, —. A. A. BOEHTLINGK

**Modern developments in soap manufacture.** H. M. LANGTON. *Ind. Chemist* 5, 65–70, 105(1929). E. H.

**Making soap in closed kettles.** G. MARGOLIN. *Masloboino Zhirovoe Delo (Oil and Fat Ind. (Russia))* 1928, No. 5, 10–1.—Twenty-five % less steam is used for boiling soap when the boiling is done in closed kettles; the same quality of soap is obtained as in open kettles. A. A. BOEHTLINGK

**Dyeing fatty acids** (Brit. pat. 299,790) 25. Device for separating oil, water and air (U. S. pat. 1,714,825) 1. Filter and gravity separator for oil and water, etc. (Brit. pat. 299,648) 1.

HOLDE, D.: *Huiles et graisses minérales, végétales et animales, etc.* Translated from the 6th German ed. by Ad. Jouve. Paris: Ch. Béranger. 961 pp.

**Fatty substances.** RAYMOND VIDAL. *Fr.* 33,740, April 19, 1927. Addn. to 637,274 (*C. A.* 23, 536). Prepn. which are more fluid than those of *Fr.* 637,274 are obtained by substituting ricinoleic acid for oleic acid. Addns. of alkali hypochlorites or hypobromites may be made. Cf. *C. A.* 23, 1519.

**Wool fat.** I. G. FARBENIND. A.-G. *Fr.* 652,070, April 2, 1928. The fraction of wool fat having a low f. p. or liquid and more easily sol. in solvents is sapond. to obtain separately in known manner from the sapon. product, acids and nonsaponifiable fractions. The acids may be converted to soap by the addn. of NaOH soln.

**Purifying wool grease.** I. G. FARBENIND. A.-G. *Fr.* 652,613, April 12, 1928. Bleached anhyd. wool grease is obtained by heating under pressure to a high temp., e. g., 160°, the emulsions of the grease with reducing bleaching agents, such as  $\text{NaHSO}_3$ , lye or  $\text{SO}_2$  soln.

**Purifying fatty vegetable oils.** ANTHONY S. MORRIS (to Cresson-Morris Co.). U. S. 1,714,231, May 21. A body of oil and admixed alkali soln. is heated and a portion of the oil is continuously withdrawn from the lower portion of the body and returned beneath the level of the body and within the latter in cyclic circulation so as to cause the returned portion to circulate through and to intermix with the body before being again withdrawn. An app. is described.

**Apparatus for the preparation of olive oil.** RAOUL M. BERLINE. *Fr.* 652,818, Feb. 7, 1928.

**Candelilla wax.** JOSE T. GARCIA. U. S. 1,715,194, May 28. The plant material from which the wax is to be estd. is subjected to crushing, tearing and beating so that

wax and non-waxy matter in finely divided form are sepd. from the plant fibers and then subjected to screening, in an app. which is described.

**Hand-cleansing composition.** ADREN B. STRAWTHER. U. S. 1,714,054, May 21. A compn. suitable for removing paint, etc., from the skin comprises finely divided wood 300,  $\text{Na}_2\text{CO}_3$  280, soap 280, Na borate 25 and powd.  $\text{NH}_4\text{Cl}$  about 5 parts.

**Hand-washing powder.** KURT RÖHLER. U. S. 1,713,920, May 21. A mixt. is formed from dry finely ground wood pulp 15, sal soda 12, neutral fat 3, green soap 7, finely pulverized pumice 1.5 and turpentine varnish 1 part, and is suitable for use on the skin or on fabrics.

**Apparatus for casting soap into bars.** L. H. NELLES. Brit. 299,960, Sept. 21, 1927. Structural features.

**Rotating boiler for soap making.** LAFAYETTE H. NELLES. Fr. 652,369, April 7, 1928.

## 28—SUGAR, STARCH AND GUMS

J. K. DALE

**Report on polariscope methods (of sugar determination).** F. W. ZERBAN. *J. Assoc. Official Agr. Chem.* 12, 158-66(1929); cf. *C. A.* 22, 2479.—Results are given of collaborative expts. on the 4 generally used inversion methods as applied to mixts. of pure sugars with pure amides and amino acids (aspartic acid and asparagine). The following conclusions are drawn. In the analysis of complex mixts. resembling cane products and contg. sucrose, invert sugar, reversion products and asparagine or aspartic acid, the invertase method must be used to det. the actual sucrose content. Sucrose as detd. by Jackson and Gillis' method No. II is increased by reversion products formed under the conditions of the expts., but is not affected by the presence of asparagine or aspartic acid. Sucrose by Jackson and Gillis' method No. IV is high because of reversion products, but is low in the presence of asparagine or aspartic acid. The difference between the sucrose result by Jackson and Gillis' method No. II and by the invertase method gives an approx. measure of the reversion products produced by HCl under the conditions of the analysis. The difference between the sucrose result by Jackson and Gillis' method No. II and that by No. IV gives an approx. measure of the asparagine or aspartic acid present. The plain acid method may give any kind of a result, depending on the relative proportion of the different constituents in the mixt. analyzed.

A. PAPINEAU-COUTURE

**Influence of the temperature of refinery massecuite on hardness and destruction of sugar.** M. I. NAKHMANOVICH AND I. F. ZELIKMAN. *Nauch. Zapiski Sakharnoi Prom.* 6, 394-412(1928).—Generally very slight increase in hardness is produced by dropping a massecuite at a temp. of 105° instead of 96°. The color of the sugar boiled at the higher temp. is greater than that boiled at 96°. Apparently increase in the color more than offsets the gain in hardness.

V. F. BAIKOV

**The viscous fermentation of frozen beets.** H. COLIN AND MARC SIMONET. *Compt. rend.* 188, 943-5(1929); *J. fabr. sucre* 1929, No. 14.—The viscous product is no doubt due to a coccus, round or slightly oval, occurring singly or in short chains of 6 or 8 elements. The viscous material elaborated by the organism at the expense of the sugar is analogous to, if not identical with, the product described by earlier observers under the term "fermentation gum" or "dextran."

R. P. WALTON

**Report on drying, densimetric and refractometric methods (for the determination of moisture in sugar products).** J. F. BREWSTER. *J. Assoc. Official Agr. Chem.* 12, 156-7(1929).—A brief discussion of the lack of satisfactory methods of detg.  $\text{H}_2\text{O}$  for any but very high-grade sugar products.

A. PAPINEAU-COUTURE

**Economics of the farm manufacture of maple sirup and sugar.** JOHN A. HITCHCOCK. Vermont Agr. Expt. Sta., *Bull.* 285, 1-96; *Bull.* 286, 1-24(1928).—A very complete study of cost data as related to maple products in the U. S.

C. R. F.

**The spontaneous decomposition of sugar-cane molasses.** C. A. BROWNE. *Ind. Eng. Chem.* 21, 600-6(1929).—Periodical analyses of 2 samples of sugar-cane molasses that had undergone deterioration extending over a period of 14 yrs. showed: (1) a progressive lowering in polarization, (2) a constantly increasing loss of sucrose, (3) a slow, irregular increase in the % of invert sugar, (4) a constantly increasing loss in the total sugars after inversion, and (5) a const. increase in the % of org. non-sugars. These changes resulted from chem. activities within the molasses and not from fermentation by microorganisms. This spontaneous decompn. is apparently a retarded type of "froth" or "hot room" fermentation. Two explanations are offered: (1) the forma-

tion of unstable compds. as glucic acid by the action of lime, introduced during clarification, upon the reducing sugars, and (2) the formation of unstable compds. by the acid of the amino acids of the molasses upon the reducing sugars. The part each probably plays in the deterioration is considered.

**Solid molasses.** STAIGER and GLAUBIT. *Brennerei-Ztg.* 46, 78(1929).—Sun-dried samples of sugar cane molasses received from N. Africa were heavily infested with a variety of microorganisms. 100 g. solid molasses gave on fermentation 31.75–34.25 cc. alc., total N = 0.32% (only 0.01% N utilizable by yeast); % H<sub>2</sub>O = 8.22; 20 g. solid molasses neutralized 0.6 cc. N alkali.

**The effect of heat on tragacanth and its mucilage.** L. F. GABEL. *J. Am. Pharm. Assoc.* 17, 1206–10(1928).—In the prepn. of tragacanth mucilage one- and two-min. boiling periods produce an initial max. viscosity, which increases greatly upon aging. Three-minute boiling produces a mucilage of high viscosity, which aging does not materially change. Prolonged boiling decreases the viscosity of the mucilage to a great degree. Heat has a deleterious effect on powd. tragacanth. Loss of moisture seriously impairs the powd. gum.

Filtering equipment and the systematic and continuous extraction of precipitates (FOURTON) 1. Determination of glucose sirup and glucose in presence of sucrose and invert sugar (KRUISHEER) 12. The saponin of the sugar beet (REHORST) 10. Dehydrating (of sugar beets) (U. S. pat. 1,713,619) 13. Paper pulp (from bagasse) (Brit. pat. 299, 740) 23.

KLINGE, G.: *Notas sobre la industria azucarera del Hawaii*. Lima, Peru: Sociedad nacional agraria. 220 pp. Reviewed in *Expt. Sta. Record* 60, 436 (1929).

**Fine soft granulated sugar.** BERNARD H. VARNAU and TRUMAN B. WAYNE U. S. 1,715,049, May 28. A comparatively concd. sucrose soln. is maintained substantially free from crystals at a temp. of 60–100° and is rapidly cooled to effect a substantially complete and regular grain setting, further maintained at a crystg. temp. and the crystals are sepd. from mother liquor. An app. is described. Cf. C. A. 23, 1522.

**Treating sugar solutions with lime.** RALPH W. SHAFOR. U. S. 1,713,925, May 21. A continuous reaction in a series of steps is first effected between lime and sucrose soln. to the point of concn. of the lime at which the alk. approaches a max. point as the reaction is completed, and reaction in a series of steps is then effected between the product of the first reaction with lime to produce a ppt. of lime and sucrose; the material in the second reaction is kept from mixing with the material undergoing the first reaction. An arrangement of app. is described.

**Apparatus for extracting sugar from beets.** A. A. SHUMILOV, YU. D. LYUBCHENKO and R. R. KRAUSS. Russ. 5755, June 30, 1928. Mechanical features are specified. Starch. CORN PRODUCTS Co., LTD. Fr. 652,360, Apr. 7, 1928. See Brit. 288,516 (C. A. 23, 728).

## 29—LEATHER AND GLUE

ALLEN ROGERS

Collected references on colloid technic. Colloid chemistry in the tannery. G. SANDOR. *Kolloid-Z.* 48, 96–103(1929).—A survey is made of the literature on the colloid chemistry of tanning based on: the chemistry of the proteins, the swelling of hides, vegetable tanning materials, chrome tanning, other mineral tanning materials, fat liquoring and finishing.

**Tanniferous barks of Madagascar. II. Bark of Terminalia catappa** L. A. DEFORGE, J. MAHEU and F. HEIM DE BALSAC. *Halle aux cuirs* 1929, 118–23; cf. C. A. 23, 2845.—The fruit of *Terminalia* (myrobalams) is its chief contribution to the leather industry, but the bark of some varieties is also rich in tannin. H. B. M.

**The modified shake method for tannin analysis and the Darmstadter apparatus.** G. BALDRACCO. Nat. Inst. for the Leather Ind., Turin. *Boll. ufficiale staz. sper. ind. pelli nat. concianti* 7, 82–94(1929).—B. stresses the exactness and simplicity of his 2 modifications (C. A. 15, 2366; 19, 3070) of the official method for the detn. of non-tannins in tanning liquids. The advantages of performing the analysis according to his method in the Darmstadter app. are pointed out. Parallel detns. always gave con-

cordant results; the values obtained agreed closely with those obtained with the official method. The detannizing was complete. The following procedure is recommended: Dry hide powder (8.5 g.) chromed in advance with chrome alum is introduced into the Darmstadter app. Seventy-five cc. of the tanning liquid is added. The app. is closed and agitated for 15–20 mins. Then the washing liquid is removed by suction and 75 cc. of the tannin soln. is added. After shaking for 15 mins. the soln. is removed by suction and filtered. The detn. of the nontannins in 50 cc. of the clear filtrate is carried out according to the usual method. A minor change in the construction of the Darmstadter app. is proposed.

G. SCHWOCH

**Synthetic tanning materials. I. Hydroxybenzene series.** G. GRASSER. *J. Faculty Agr. Hokkaido Imp. Univ.* 24, 73–92(1929).—The manuf. of syntans always involves a condensation reaction. Different types of condensations are reviewed. For syntans, the most important condensation is that in which  $H_2O$  is eliminated, and the most important agents are  $HCl$  and  $H_2SO_4$ . The technically important syntans are formed by the union of 1 mol. of aldehyde or ketone with 2 mols. of aromatic hydrocarbons or substitution products thereof, including phenols and their ethers. Very numerous qual. expts. were made in which various aldehydes were condensed with  $C_6H_5OH$ ,  $C_6H_5ONa$ , or  $HOC_6H_4SO_3H$ , in various solvents, with and without  $H_2SO_4$  present. When a  $H_2O$ -sol. product was obtained, its pptg. power toward gelatin was tested.  $HOC_6H_4SO_3H$  is much more readily condensed than  $C_6H_5OH$  or  $C_6H_5ONa$ . With the former, in  $H_2O$ , most  $H_2O$ -sol. aldehydes and ketones, including glucose and lactose, but not "cellulose ext.," are readily condensed. In  $EtOH$  soln.,  $HCHO$  and  $CH_3CHO$  react readily; salicylaldehyde and protocatechualdehyde react only in presence of  $H_2SO_4$ , forming insol. resins, which, however, are sol. in  $NaOH$ , forming solns. that are not pptd. by acid and have tanning properties; glucose and lactose cannot be condensed with  $HOC_6H_4SO_3H$  in  $EtOH$  soln., even in presence of  $H_2SO_4$ ; "cellulose ext.," on the other hand, reacts readily, forming a compd. possessing tanning properties.  $HCHO$  is readily condensed with  $HOC_6H_4SO_3H$  in soln. in  $(CH_3)_2CO$ ,  $(CH_3CO)_2CO$ ,  $CH_3COOEt$ ,  $HAc$  and  $C_2H_5(OH)_2$ , giving  $H_2O$ -sol. compds. that ppt. gelatin.

H. B. MERRILL

**A few south-Japanese tanning materials.** G. GRASSER. *J. Faculty Agr. Hokkaido Imp. Univ.* 24, 61–72(1929).—Japan is almost wholly dependent upon importation for tanning materials. In Formosa, however, many tanniferous species are available. Nine species were examd. to det. the kind and amt. of tannin and suitability for tanning. Results:

Species	Structure	% tan- nin (dry)	Tannin like	Remarks
<i>Q. castanopsisifolia</i>	Acorn cups	28.3	Valonia	Recommended
<i>Q. amygdalifolia</i>	Acorns	6.1	—	—
<i>Q. glandulifera</i>	Galls	20.4	European galls	Recommended
<i>Areca catechu</i> L. (Betel nut)	Nuts	12.3	Mangrove	Difficult to ext.
<i>Castanopsis taiwaniana</i> Hayata	Wood	2.0	—	Bark recommended
	Bark	9.2	—	—
<i>Castanopsis kawakamii</i> Hayata	Wood	3.3	Pine bark	Bark recommended
	Bark	9.3	Pine bark	—
<i>Acacia confusa</i> Merr	Bark	12.0	Quebracho	Recommended
<i>Dioscorea rhipogonoides</i> Oliv.	Root nodes	30.0	—	Recommended
<i>Diospyros kaki</i> (Persimmon)	Fruit	—	—	Tannin too unstable for use.

H. B. MERRILL

**Examination of raw hide.** G. GRASSER. *J. Faculty Agr. Hokkaido Imp. Univ.* 24, 97–9(1929).—Raw skin is sometimes analyzed to det. the method of curing and preservation employed. Qual. and quant. examn. of mineral constituents usually suffices. Analyses of mineral matter from arsenicated, salted and dried skins from the orient are given.

H. B. MERRILL

**Influence of hydrogen-ion concentration on the color of vegetable-tanned leather.** R. O. PAGE AND A. W. PAGE. *Ind. Eng. Chem.* 21, 584–5(1929).—It is shown that when strips of skin are pretreated with solns. of  $pH$  values from 1 to 9 and tanned with wattle or chestnut liquors of the corresponding  $pH$  values, the depth of color of the leather rises and falls with  $pH$  value in a manner very similar to the swelling curve of skin. Strips all pretreated at  $pH$  5 and tanned in liquors of  $pH$  1 to 9 showed progressive darkening with increasing  $pH$ , corresponding to change of color of liquor with

$p_H$  value. Strips pretreated at  $p_H$  2 and 13, then brought to  $p_H$  5 and tanned at  $p_H$  5, were both darker than strips pretreated at  $p_H$  5. These effects are attributed to changes in structure of collagen due to pretreatment.

The dyeing of gloving leathers. J. W. LAMB. *Dyer, Calico Printer* 61, 168-9 (1929); cf. *C. A.* 22, 3550.—General. Formulas are given. H. B. MERRILL  
RUBY K. WORNER

Qualitative investigation of chrome-leather spews. G. GRASSER. *J. Faculty Agr. Hokkaido Imp. Univ.* 24, 93-6 (1929).—Spews may be composed of fats, fatty acids, S, salts, or mold growths. Microscopic examn. followed by microchem. tests is advised. H. B. MERRILL

Leather. SIEGFRIED STRANSKY. *Fr.* 651,853, Mar. 28, 1928. Two pieces of skin of fish such as large ray are passed through lime, placed one on another so that the inner sides touch, joined at the edges and submitted to tanning for the production of fancy leather.

Finishing leather. A. O. T. BEARDMORE. *Brit.* 300,077, April 3, 1928. In finishing and removing blemishes from leather, the dried tanned hide is caused to absorb 20-25% of water, stacked to effect even penetration of the water, sprayed with a mixt. of mineral and vegetable oils at about 140°, rough-rolled and finally subjected to hot embossing under heavy pressure.

"Leather substitute." ROBERT A. MARR. U. S. 1,713,846, May 21. Material contg. digested wood is subjected to brush beating at a speed not substantially below 1000 ft. per min., a sizing is added, a portion of the disintegrated binding matter is removed and the product is formed into sheets.

Imitation leather. CHARLES H. DENNISON (to American Rubber Co.). U. S. 1,713,746, May 21. A strain-resisting flexible backing such as woven textile fabric is coated with a rubber compn., a layer of fibrous rubber compn. is applied over the first rubber layer, the material is subjected to vulcanization and then to abrasion to expose the ends of the fibers.

### 30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

Belt dressing for eliminating static. P. W. EDWARDS AND J. O. REED. *India Rubber World* 80, 60 (1929).—Static electricity can be eliminated from rubber or leather belts by the use of special belt dressings. A good non-static rubber belt dressing contains spar varnish 82, lampblack 18, it is allowed to dry before running the belt. For leather belts the following mixt. is especially good: liquid fish glue 100, glycerol 80, sulfonated castor oil 100, water 170, 2%  $NH_4OH$  20 cc. and lamp black 82 g., in some cases more fish glue and glycerol being advisable. Conditions favoring the production of static electricity and methods of preventing it are described. C. C. DAVIS

The generation of rubber. R. L. DUPONT. *Rev. gén. mat. plastiques* 4, 621-3, 745-51 (1928); 5, 237, 239 (1929).—A review. A. PAPINEAU-COUTURE

Rubber, with special reference to the use of lead compounds. J. R. SHEPPARD. *Trans. Am. Inst. Chem. Eng.* 20, 187-212 (1928).—A review and discussion, with illustrations and tabulated data, dealing with the phys. properties of vulcanized rubber, vulcanizing agents, accelerators and compounding ingredients, with particular reference to Pb compds. C. C. DAVIS

Active fillers for rubber. MARJA SAGAJLO. *Przemysl Chem.* 13, 154-7 (1929).—A review with bibliography. A. C. ZACHLIN

Coagulation phenomena in Hevea latex. VIII. Influence of some heavy metal salts on coagulation and coalescence. OTTO DE VRIES AND N. BEUMÉE-NIEUWLAND. *Arch. Rubbercultuur* 13, 125-204 (1929); (in English 205-18); cf. *C. A.* 23, 1771.—In studying the effect of  $MnSO_4$ ,  $CuSO_4$ ,  $NiSO_4$  and  $HgCl_2$  on coalescence and coagulation, the aq. salts were added to undild. latex, to latex dild. to various degrees and to heated dild. latex, with and without the simultaneous addn. of  $AcOH$ , the addns to heated latex being for the purpose of detg. the influence of the salts on the coalescing power of fresh latex and of exts. contg. coalase. The results of the expts. are summarized in the following data, the arithmetical values representing in all cases the concn. of the salt in mg.-mols. per l. in the liquid in question: Coalescing power (in B mixt.)— $MnSO_4$ , weak, coalescence in 24 hrs. by 35 and in 2 days by 10;  $NiSO_4$ , no effect;  $CuSO_4$ , weak, coalescence in 24 hrs. by 64 and a trace of coalescence in several days by 32;  $HgCl_2$ , distinct, coalescence in 2.5 hrs. by 40-50, in 24 hrs. by 20 and a trace in several days by 2.5. Coagulating power.— $MnSO_4$ , distinct, coagulation in

undild. latex in 1-2 hrs. by 13, flocculation in dild. latex (1:9) by 7 and coagulation in undild. latex (1:9) in a short time by 33;  $\text{NiSO}_4$  distinct, coagulation in undild. latex in 0.25 hr. by 16, and in dild. latex (1:9) a clot in 0.25 hr. by 8;  $\text{CuSO}_4$  distinct, in undild. latex a thickening or pasty condition by 10-20, coagulation in 24 hrs. by 30-60, and in dild. latex (1:9) flocculation by 2 and coagulation in a few hrs. by 30;  $\text{HgCl}_2$  distinct, undild. latex became viscous with 5-10 and coagulated in 24 hrs. with 40, and dild. latex (1:9) flocculated with 1 and coagulated in 24 hrs. with 20. *Effect on heated latex (1:9 B mixt.) without acid.*— $\text{MnSO}_4$  flocculation by 3.3, coalescence after 3 days by 33, and after 2 days by 80;  $\text{NiSO}_4$  flocculation (with a white serum) by 2.4, flocculation (with a clear serum) by 40, with no coalescence;  $\text{CuSO}_4$  flocculation in 24 hrs. by 8, rapid flocculation, by 64, coalescence after a few days by 46;  $\text{HgCl}_2$  flocculation in a few hrs. by 0.5, coalescence in 1 day by 10, coalescence in a few hrs. by 40. *Influence on coagulation by AcOH.*— $\text{MnSO}_4$  acceleration caused by 3.3 or more in undild. latex, and by 5-6 or more in dild. latex (1:9);  $\text{NiSO}_4$  acceleration caused by 8-16 in dild. latex and by 2-6 in dild. latex (1:9);  $\text{CuSO}_4$  flocculation promoted with formation of a paste or porridge-like mass, but coalescence retarded by 0.8-4, and accelerated by 12-40, while in dild. latex (1:9) syneresis proceeded very slowly;  $\text{HgCl}_2$  flocculation promoted as with  $\text{CuSO}_4$ , coalescence retarded more strongly than with  $\text{CuSO}_4$  with 0.5-10, while 75 or more accelerated coagulation. *Destruction of coalescing power of exts.*— $\text{MnSO}_4$ , no effect,  $\text{NiSO}_4$  distinct, 40-80 diminishing the power greatly and 130-200 nearly destroying it altogether;  $\text{CuSO}_4$  strong, the power being destroyed by 0.8 or more;  $\text{HgCl}_2$  strong, 0.5 or more destroying the power. *Spontaneous coagulation by bacterial acid formation.*— $\text{MnSO}_4$  no effect;  $\text{NiSO}_4$  no effect;  $\text{CuSO}_4$  coagulation of undild. latex inhibited by 4, and of dild. latex (1:1) inhibited by 2;  $\text{HgCl}_2$  coagulation of undild. latex inhibited by 5 and of dild. latex (1:1) inhibited by 0.75.  $\text{CoSO}_4$  was not available, but tests of  $\text{Co}(\text{NO}_3)_2$  indicated that it would have much the same properties as  $\text{NiSO}_4$ . The results show that the phenomena are varied and complicated.  $\text{MnSO}_4$ ,  $\text{NiSO}_4$  and  $\text{Co}(\text{NO}_3)_2$  showed in general the normal behavior of bivalent salts except that  $\text{NiSO}_4$  in high concns. diminishes the coalescing power and has no coalescing power itself (whereas  $\text{MnSO}_4$  has a weak coalescing power).  $\text{CuSO}_4$  however, acts abnormally, particularly in that coagulation by  $\text{AcOH}$  is greatly retarded at certain concns. of  $\text{CuSO}_4$ , and in that the coalescing power of fresh latex and exts. is diminished or destroyed.  $\text{HgCl}_2$  is also noteworthy in its power of destroying the coalescing power of fresh latex and exts. contg. coalse.  $\text{AgNO}_3$  (0.6 and 1.2 mg.-mols. per l.) did not coagulate dild. latex (1:1); in fact spontaneous coagulation was retarded. Coagulation by  $\text{AcOH}$  is uninfluenced by 0.6 mg.-mols. and is retarded by 1.2 mg.-mols. It has a weak coalescing effect. C. C. DAVIS

**Volume compounding.** F. HARRIS COTTON. *India Rubber J.* 77, 583-4(1929).—

A discussion of the principles.

C. C. DAVIS

**China clay as a reinforcing agent in rubber compounding.** T. J. DRAKELEY AND W. F. O. POLLETT. *Trans. Inst. Rubber Industry* 4, 424-60(1929).—Since clays are cheaper than C blacks and can also be used in light-colored rubber products, an extensive investigation was made of the suitability of china clays as reinforcing agents and the quality obtained in comparison with C blacks under the same conditions. The base mixt. contained: pale crepe 100,  $\text{ZnO}$  5, S 4, diphenylguanidine 1, to which were added various proportions of the pigments. The phys. tests of the cured mixts. included the relation between tensile products and times of cure, the influence of temp. on the stress-strain curves, stress-strain curves and their comparative curvatures, resilient energy, the effects of softeners and the relative stiffness of the various samples. The data are given in detail in tables and graphs, and the results may be most readily summarized from the following conclusions: None of the clays retarded the rate of vulcanization, and some had a mild accelerating action. On the other hand, the C blacks had a retarding action. The accelerating action of some clays was probably closely related to their alkali content, for equiv. quantities of  $\text{Na}_2\text{CO}_3$  had the same effect. Small proportions of stearic acid did not influence the accelerating action of the clays, but did eliminate the retarding action of the C blacks. The extent of these accelerating or retarding effects was proportional to the quantity of pigment. The lower the temp. at which the mixts. were tested, the lower the elongation and the greater the tensile strength. Increasing proportions of clays displaced the stress-strain curve toward the stress axis in a way typical of reinforcing pigments. Up to 18% by vol. (based on the rubber) the clays increased the tensile strength, and the best clays increased the tensile strength more than did equal vols. of the C blacks. Up to 25% by vol., the clays increased the resilient energy, the max. being reached at about 12%. These max. resilient energy values were greater than the corresponding

ones with C black, but the clays failed to reinforce at such high loadings as the best C blacks. Small proportions of stearic acid did not influence the % vol. of clay or of C black at which the max. energy values occurred. With clays, stearic acid reduced the tensile strength and resilient energy values, whereas with C blacks it increased it. The slope of the stress-strain curve of the base mixt. was increased at first by clay or C black, but in some cases a max. was reached, beyond which the slope diminished with more pigment. The stress required to obtain a given elongation does not represent the stiffness of a cured mixt., particularly when the effect of increasing proportions of pigments is taken into account. Stiffness is more satisfactorily expressed by the elongation which a given stress produces. The C blacks increased the stiffness more than did the corresponding vols. of clays, and though stearic acid was without effect with small proportions of pigment, at higher proportions it further increased the stiffness. This stiffening action of the clays and C blacks had little relation to their effects on the tensile strengths. Clays did not increase the concavity factor (cf. Wiegand, C. A. 19, 2423, 3386) of the base mixt. so much as did the same vols. of the C blacks. With increase in the % pigment, the effect on the concavity factor gradually diminished, while this factor was not affected by small proportions of stearic acid. C. C. DAVIS

The influence of selenium red on the physical properties of accelerated rubber mixtures. RUDOLF DITMAR. *Chem.-Ztg.* 53, 239(1929).—A study of the action of Se red (cf. C. A. 23, 1526) on the phys. properties of rubber-S-ZnO-CaCO<sub>3</sub>-Se red-accelerator mixts. vulcanized with 19 different accelerators showed that it behaves like the com. grade of Se called "Vandex," the reinforcing effect depending upon the accelerator and being inappreciable with some accelerators. C. C. DAVIS

The behavior of the selenium preparation "Vandex" in rubber mixtures. RUDOLF DITMAR and MANFRED RACHNER. *Gummi-Ztg.* 43, 1583-4(1929).—Tests of the phys. properties of different cured rubber mixts. contg. Se (in the form of Vandex) show that (1) in a mixt. contg. rubber 100, S 5, CaCO<sub>3</sub> 20, Vandex 2, the Vandex stiffened the cured mixt., whereas with much higher proportions this stiffening action was diminished; (2) in a mixt. contg. rubber 100, S 5, ZnO or PbO or MgO 10, CaCO<sub>3</sub> 20, Vandex 2, the Vandex had a stiffening effect with ZnO, but had no effect with PbO or MgO; (3) in a mixt. contg. rubber 100, S 3, PbO 10, CaCO<sub>3</sub> 30, accelerator 2, Vandex 2, the Vandex had a stiffening effect with some accelerators, whereas with others it had no effect; and (4) in a mixt. contg. rubber 100, S 3, ZnO 10, CaCO<sub>3</sub> 30, accelerator 2, Vandex 2, the Vandex had a high stiffening effect with some accelerators, whereas with other accelerators its effect was negligible. The accelerators with which Vandex showed a stiffening effect in conjunction with PbO were different in some cases from those accelerators with which it showed a stiffening action with ZnO. Therefore the stiffening action of Vandex depends upon the accelerator and other factors, and it must be detd. for the individual case. C. C. DAVIS

The nature of vulcanization. IV. H. P. STEVENS and W. H. STEVENS. *J. Soc. Chem. Ind.* 48, 55-9T(1929); cf. C. A. 22, 1703.—A survey of the literature shows that there is still uncertainty concerning the max. proportion of S, which under the most favorable conditions will combine with rubber on vulcanization. Expts. were therefore carried out, under conditions different from those of previous investigators, to det. the max. limit of combined S. Prolonged vulcanization was carried out at 100° by the aid of Zn diethyldithiocarbamate (cf. *British Patent* 269,693, C. A. 22, 1498), which minimized the decompn. of the rubber. If the Zn diethyldithiocarbamate remained unaltered during vulcanization, it would be removed on acetone extn., whereas if it were decompd., ZnS would be formed. The technic took care of each possibility, the acetone-extd. rubber having been analyzed directly for combined S, and the vulcanizates also having been extd. with HCl in Et<sub>2</sub>O to remove any ZnS. The results were such that, even if all the Zn were converted to ZnS and allowance were made for this in the calcs., the combined S of the hard rubber was considerably in excess of that corresponding to C<sub>6</sub>H<sub>8</sub>S. Extn. of the hard rubber with HCl-Et<sub>2</sub>O mixt. removed part of the combined S; the greater the proportion of the latter the more was removed, but in all cases the proportion remaining was considerably greater than that corresponding to C<sub>6</sub>H<sub>8</sub>S. This was true whether the rubber was ordinary crepe, sprayed rubber or partially purified rubber, whether vulcanization was carried out in the ordinary way or by the solvent method of Whitby and Jane (cf. C. A. 20, 2763), and regardless of the excess S. With prolonged vulcanization, the proportion of combined S depended chiefly upon the excess of S. The H<sub>2</sub>S and other volatile S compds. evolved in appreciable quantities during vulcanization being considered, the results show that part of the combined S is accounted for by substitution of H by S. This substitution product is decompd. by the treatment with HCl-Et<sub>2</sub>O mixt., though it is probably impossible to decomp. all of this S-

substitution product. Consequently, any combined S in excess of that corresponding to  $C_4H_8S$  may be the result of substitution. Degradation products contg. combined S were not formed, the brown substance remaining in the acetone ext. after removal of free S from the latter contg. no S compds. but probably being composed of decompn. products derived from non-rubber components. Even with continued acetone extrn. for several months, small quantities of free S were still being removed. C. C. D.

**New microscopic methods in connection with the problems of vulcanization.** E. A. HAUSER, H. MIEDEL AND M. HÜNEMÖRDER. *Colloid Symposium Monograph* 6, 207-17 (1928).—By means of a tiny vulcanization chamber, which is illustrated, vulcanization of the following mixts. was followed microscopically: (1) 100 rubber, 3 S; (2) same as (1) plus 5 ZnO; (3) same as (2) plus 1 accelerator. With (1), when undecured, S reappears as colloidal globules which grow and form dendrites. ZnO retards this process, dendrites being marked. Accelerators seem to prevent sepn. of the S, except at the surface (blooming), and may thus be recognized. Thiuram disulfide slowly forms needle-shaped deposits, which aggregate into half-moon shaped crystals of unknown compn. While (1) and (2) show marked flow at the beginning of vulcanization, (3) shows only slight flow, which stops abruptly. Ether-sol.  $\alpha$ -rubber vulcanizes more slowly and requires a higher temp. than whole rubber, or  $\beta$ -rubber. The view is advanced that vulcanization "depends on minute traces of a substance present in crude rubber, a substance which firmly adheres to the  $\alpha$ -fraction, so that it can be removed only after this fraction has been isolated from its original combination in the rubber." JEROME ALEXANDER

**The consumption of accelerator during vulcanization.** L. v. WISTINGHAUSEN. *Kautschuk* 5, 57-61, 75-7 (1929).—The extent to which accelerators of different types disappear during vulcanization was studied by curing accelerated base rubber mixts. with different proportions of S, with and without ZnO, and by detg. the proportions of accelerator remaining after increasing times of cure. The 2 accelerators chosen were diphenylguanidine (I) and mercaptobenzothiazole (II). Throughout the expts. they were used in the same proportion by wt. The stress-strain curves of the vulcanizates were also obtained to det. whether there is any relation between the stability or fugitiveness of an accelerator and its activity. In all cases the consumption of I and II increased progressively with the duration of cure, approaching a max. in each case. All the results are given in graphical form, and it is this max. which shows most clearly the influence of the type of rubber, the type of accelerator, the % S, the presence or absence of ZnO and the time of vulcanization on the extent of the disappearance of the accelerator. Without ZnO, I disappeared much more rapidly than II, and this was reflected in a greater accelerating power by I, the stress-strain curves showing stiffer, stronger vulcanizates for given cures. With other conditions equal (with or without ZnO, etc.), more I and II disappeared with 1st latex crepe than with sprayed rubber or Peru rubber. This had no relation to the phys. properties of the vulcanizates, for the stress-strain curves bore no relation to the accelerator consumption. The disappearance of I and II was smallest without ZnO; with increasing proportions of ZnO (up to 12 parts per 100 parts of rubber) progressively higher proportions of I disappeared. The stress-strain curves showed that ZnO had an activating effect. Without ZnO, the higher the % S the greater the proportion of I but the less the proportion of II which disappeared. With ZnO, the higher the % S the greater the proportions of both I and II which disappeared. In all cases the rate of vulcanization (judged by the stress-strain curves) increased with the % S. The results indicate that the accelerating power depends in some way upon its reactivity and disappearance in the reaction, rather than upon a catalytic effect. Where no appreciable part of the accelerator disappeared, there was no accelerating effect. The formation of complexes of accelerators and Co salts of unsatd. org. acids makes it probable that complexes of I and II with ZnO are formed during vulcanization. Such complexes would increase the soly. of the accelerator in the rubber, and would also increase the electro-positive state of the Zn and thus activate the S (cf. Scholz, *C. A.* 21, 2399). The increase in consumption of accelerator with increase in the % S indicates, furthermore, that S takes part in this complex formation. It is also possible that a rubber-accelerator compd. is formed. The expts. were not carried far enough to find a relation between the consumption of accelerator and the increase of combined S (cf. Hardman and White, *Gummi-Ztg.* 1927, 305; cf. *C. A.* 21, 4098). Twiss has already found (*Gummi-Ztg.* 1928, 2307; cf. *C. A.* 22, 2491; 23, 2070) that a combined S-cure curve gives no indication of the optimum cure, and similarly the present expts. show that there is no apparent relation between the progressively increasing consumption of accelerator and the changes in phys. properties. The consumption of accelerator was measured

indirectly by detg. the residual accelerator extractable with hot acetone. *Detn. of I.*—Ext. 20 g. of finely divided rubber for 12 hrs. in a Soxhlet app. with acetone, evap. the ext., dissolve in Et<sub>2</sub>O, add 10 cc. of aq. 0.1 N HCl, evap. the ether, cool, filter, dissolve the residue in Et<sub>2</sub>O, treat as before with HCl; repeat this 3 times; wash the final residue with water; to the combined filtrates (not over 50 cc.) add 50 cc. of 1% aq. picric acid, let stand overnight, filter through a weighed Gooch crucible, wash with 5 cc. of water, and dry at 100°. With overcured vulcanizates the final picrate may have a dark brown color, and probably contains decompn. products. *Detn. of II.*—Ext. 100 g. of finely divided rubber for 12 hrs. in a Soxhlet app. with acetone, evap. the ext., dissolve the residue in 20 cc. of warm C<sub>6</sub>H<sub>6</sub>, filter, wash with C<sub>6</sub>H<sub>6</sub>; to the filtrate add an excess of 3% filtered C<sub>6</sub>H<sub>6</sub> soln. of Cu oleate until the soln. remains green and let stand overnight, centrifuge, wash the ppt. with C<sub>6</sub>H<sub>6</sub> and then with petr. ether, dry at 140° and weigh. The reaction is:  $2\text{II} + \text{Cu}(\text{C}_{18}\text{H}_{33}\text{O}_2)_2 \longrightarrow 2\text{C}_{18}\text{H}_{33}\text{O}_2 + \text{CuC}_7\text{H}_4\text{NS}_2 + \text{C}_7\text{H}_4\text{NS}$ , the C<sub>6</sub>H<sub>6</sub>-sol. Cu salt which is formed being transformed into a C<sub>6</sub>H<sub>6</sub>-insol. Cu salt and dibenzothiazolodisulfide (like the decompn. of Cu(CN)<sub>2</sub> to CuCN and (CN)<sub>2</sub>). In the Cu ppt. is 0.5 of the II, so that this must be multiplied by the factor 1.4556; to obtain the quantity of II extd. by the acetone.

C. C. DAVIS

**The oxidation of vulcanized rubber.** A. VAN ROSSEM AND P. DEKKER. *Rubber Age* (N. Y.) 25, 85-8, 143-5(1929).—An English version of *C. A.* 23, 2598. C. C. D.

**Onazote.** J. C. G. KUNHARDT. *Bull. Rubber Growers' Assoc.* 11, 222-8(1929).—"Onazote" is a type of vulcanized rubber which has been made to absorb a neutral gas under pressure during vulcanization and is thus expanded into a highly cellular condition. The gas is retained under pressure, and the product may be molded into any desired form, and can be made soft and resilient, or hard. Unlike sponge rubber it is non-absorbent and has certain notable characteristics, *e. g.*, (1) it is the best non-conductor of heat; (2) it is the lightest solid known (3-7 lbs. per cu. ft.); (3) the soft variety is by far the most compressible solid in existence and has a recovery almost the same as that of air; (4) it is an extremely efficient absorber of shock and vibration; (5) it is probably the best non-conductor of sound; and (6) its great expansion during vulcanization allows better molding than ordinary rubber mixts. The unique properties of Onazote make it of great value for a very wide variety of uses, many of those already tried or suggested being mentioned.

C. C. DAVIS

**Temperature coefficient of vulcanization of a litharge compound.** J. R. SHEPPARD. *India Rubber World* 80, 56-60(1929); *cf. C. A.* 22, 4272.—Exptl. data on the stresses at intermediate elongations, tensile strength, ultimate elongation, tensile product, energy and free S of a mixt. contg.: rubber 100, S 8, PbO 15, stearic acid 1 and ZnO 44, vulcanized to different degrees, were utilized to construct graphs showing the time of cure as a function of the temp. for const. values of the 6 properties mentioned above. There were no significant differences in the temp. coeffs. for the several properties. The coeffs. of the various properties varied from 12.6 for strength at 300 and 600%, elongations to 13.7 for tensile product, with an av. of 13.1, *i. e.*, to halve or to double the time of cure required a change of 13.1° F. This method may be applied to the study of vulcanization in general and to accelerator action in particular, *e. g.*, the more exact evaluation of the suitability of an accelerator for low or high temp. cures, the comparative effects of various methods of curing (air, steam, mold, etc.), the instability of accelerators to avoid scorching, comparisons of different activators with different accelerators, the adsorption of accelerators by reinforcing agents, etc. C. C. D.

**Lyophilic colloids.** I. Osmotic pressure and viscosity measurements of rubber solutions (KROEPFLIN) 2. The preservation of tropical fruits with latex (SPOON) 12. Printing ink suitable for use on rubber (U. S. pat. 1,715,209) 26. Imitation leather (U. S. pat. 1,713,746) 29.

**Rubber.** THE DUNLOP RUBBER CO., LTD. Fr. 652,439, Apr. 10, 1928. Viscous liquid or semi-solid accelerators, anti-aging agents, or softeners are mixed or combined with colophony before compounding them with rubber. Examples are given. Hardened rosin and substances such as ZnO or clay may be added to vary the consistency.

**Recovery of latex from storage-tank settlings by centrifugal treatment.** AKTIEBOLAGET SEPARATOR. Brit. 299,808, Nov. 1, 1927.

**Deposition of rubber.** THE ANODE RUBBER CO. (England), LTD. Fr. 651,730, Mar. 24, 1928. The constitution of the electrophoretic deposition of rubber is acted upon by varying the content of electrolytes practically free from OH ions in the dispersion. Thus, the content of such electrolytes may be decreased by dialysis, or in-

creased by addn. of more of such electrolytes. Electrolytes, the anions of which form sol. or insol. compds. with the metal of the cathode, may be used. Cf. *C. A.* 23, 3375.

**Apparatus for mixing rubber compositions, etc.** WILLET B. RANNEY (to Wm. Wrigley, Jr., Co.). U. S. 1,713,554, May 21. Structural features.

**Rubber-mixing apparatus.** RICHARD C. LEWIS (to Farrel-Birmingham Co.). U. S. 1,713,969, May 21. Structural features.

**Apparatus for testing strength and stretch of rubber, etc.** DAVID C. SCOTT (to Henry L. Scott Co.). U. S. 1,714,638, May 28.

**Rubber articles.** SOCIETÀ ITALIANA PIRELLI and UGO PESTALOZZA. Fr. 651,684, Jan. 27, 1928. Small quantities of solns. or suspensions of salts of bi- or trivalent metals are added to latex, which is subsequently heated to produce coagulation or thickening of the latex. Molded articles may be produced directly by dipping heated formers into the treated latex, or by heating the latex in a mold.

**Thin-walled stretchable rubber articles.** ISTVAN DOROGI and LAJOS DOROGI (one-half to Dorogi Es Tarsa Gummigyar R. T.). U. S. 1,713,751, May 21. See Brit. 288,541 (*C. A.* 23, 731).

**Rubber bulbs or other hollow articles.** DUNLOP RUBBER CO., LTD., D. F. TWISS and E. A. MURPHY. Brit. 299,974, Oct. 5, 1927. A rod, tube, or like device carrying a bulbous enlargement of rubber having a roughened surface and of approx. the desired shape is dipped into a concd. dispersion of rubber or similar vegetable resins, followed by drying, and if desired by vulcanizing, and removal of the rod, etc. Successive dippings may be effected for increasing the thickness of the deposit, and a settling medium such as a heated soln. of  $\text{CaCl}_2$  or  $\text{NH}_4\text{OAc}$  may be used. Brit. 299,975 specifies use of a distended collapsible former for use in a similar process. Cf. *C. A.* 23, 1309.

**Molded articles by dipping formers into rubber dispersions, etc.** P. KLEIN and F. GABOR (to Dunlop Rubber Co., Ltd.). Brit. 299,737, June 28, 1927. In molding by dipping formers into dispersions such as those of rubber, gutta, balata, or mixts. of these, which may also contain proteins, cellulose esters, natural or synthetic resins, etc., the entire molds or their surfaces are formed of solid or solidified non-porous substances of such compn. that contact with the dispersion liberates agglomerating agents for the dispersion. The mold may be of a solid salt, such as an alum, which reacts with an alk. dispersion such as latex preserved with  $\text{NH}_3$ , or it may be of a metal, such as Zn or Al. Crystd. citric acid is mentioned, as are also liquid acids such as  $\text{HOAc}$  which may be solidified with collodion, and sol. salts which may be mixed with substances which are liquefiable by heat. The mold may have an inert skeleton. Emission of gas may be prevented by addns. to the dispersion or to the mold, e. g., the mold surface may be formed from a paste contg. a metal such as Al bronze powder and an oxidizing agent such as  $\text{MnO}_2$  or  $\text{PbO}_2$ . Metal molds may be coated with a film of gelatin to keep gas bubbles away from the deposit. The temp. may be raised to promote agglomeration. Cf. *C. A.* 23, 1012.

**Removing water from rubber-coated fabrics or other rubber products by electric endosmose.** C. L. DARBY (to Anode Rubber Co., Ltd). Brit. 299,713, Oct. 28, 1927. Layers or articles of rubber or the like formed from an aq. dispersion are treated by elec. endosmose for removal of water. In one method described, a metal plate coated with rubber is connected as anode while immersed in Hg or an electrolyte; exposed parts of the plate not coated with rubber are coated with wax or other insulating substance. In another method, the coated plate, connected as anode, is placed between 2 metal plates connected as cathodes. An app. and various details of procedure are described. The process is adapted for treated wire or metal strip coated with rubber.

**Rubber dressing or finish.** JAMES S. MOTTER. U. S. 1,714,919, May 28. A mixt. is formed from xylene, "petroleum spirits," Al palmitate, black aniline oil dye, gilsonite, carnauba wax and barberry wax.

**System of distributing fiber in rubber stock to form shoe soles, etc.** WILLIAM B. WESCOTT (to Rubber Latex Research Corp.). U. S. 1,714,995, May 28. Relatively long fiber is distributed so as to reinforce the rubber in all directions in a sheeted material; the latter is plated so as to possess more extensibility in one direction than in another. Cf. *C. A.* 23, 1528.

**Rubber floor and wall coverings, etc.** H. BECKMANN. Brit. 300,008, Nov. 8, 1927. Rubber floor or wall coverings and the like are coated with a thin film of porous or spongy rubber to facilitate their sticking to other materials by use of glue, pitch, resin, etc. The rubber article before vulcanization may be coated with viscous latex contg. S and vulcanization may be effected under conditions to prevent evapn. of water as described in Brit. 193,207 or the latex may contain substances which generate gas during vulcanization.

**"Self healing" composition for automobile tire tubes.** JOHN SCHWAB, JR. U. S. 1,715,213, May 28. Vulcanizing cement 30 and melted vulcanized rubber 30 parts are mixed with each other and then with honey 40 parts; the mixt. is heated to about 125°.

**Synthetic rubber.** ERNEST KLEIBER and PIERO GILARDI. Fr. 651,824, Mar. 27, 1928. Petroleum or its residues is oxidized with  $\text{Na}_2\text{O}_2$  or for several days with  $\text{HNO}_3$  after which it seps. into 2 layers, one composed of octanaphthenes, which on treatment with S are transformed to *m*-xylenes, and a turbid aq. layer, which is transformed by oxidation with fuming  $\text{HNO}_3$  to cyclohexanes and passes to adipic acid. The *m*-xylenes are mixed with the adipic acid and they also are converted to adipic acid; terpenes are then added and after heating to about 150°, isoprene and butadiene are formed, from which artificial rubber is obtained.

**Synthetic rubber.** I. G. FARBENIND. A.-G. Brit. 300,167, Nov. 7, 1927. Examples are given of processes such as described in Brit. 286,272 (C. A. 23, 310) in which polymerization of hydrocarbons is effected in the presence of a colloid and an electrolyte, *e. g.* in the presence of glue and  $\text{Na}_2\text{SO}_4$  in an atm. of O.

**Apparatus for vulcanizing rubber tires.** F. KRUPP GRUSONWERK A.-G. Brit. 299,647, Jan. 19, 1928. Structural features.

**Reclaiming vulcanized rubber.** TATSUCHI TOKOYAMA. U. S. 1,714,835, May 28. The material is treated with a hydrogenated naphthalene rubber solvent contg. dissolved therein a substance such as  $\text{NaOEt}$ , which has a strong affinity for S.

**Vulcanizing rubber.** I. G. FARBENIND. A.-G. Brit. 300,208, Nov. 8, 1927. An alicyclic base or deriv. or compd. is used as a vulcanization accelerator. The basic group may be in the ring as in decahydroquinoline, decahydroquinaldine, or perhydro-methylindol, or in non-cyclic combination as in hexahydromethyl toluidine. Various examples are given.

**Vulcanization of rubber.** THE RUBBER SERVICE LABORATORIES CO. Fr. 652,254, Apr. 5, 1928. See Brit. 297,726 (C. A. 23, 2851).

**Rubber vulcanization.** THE RUBBER SERVICE LABORATORIES CO. Fr. 652,817, Feb. 6, 1928. Compds. produced by the action of one or more mol. proportions of an aldehyde, preferably of the aromatic series, on a compd. resulting from the reaction of one mol. proportion of an aliphatic aldehyde on 2 mol. proportions of a primary aromatic amine are used as vulcanization accelerators. Examples are given.

Vol. 23.

AUGUST 10, 1929

No. 15

## 1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

**A comparison of Seitz and Mandler filters.** N. W. LARKUM. *Am. J. Pub. Health* 19, 670-3(1929).—A careful study of the comparative efficiency of Seitz and Mandler filters has shown a distinct superiority for the former. The rate of filtration and the amt. of yield have shown some advantages for the Seitz. The adsorptive capacity of the 2 filters is essentially identical. For many purposes the Seitz is unquestionably cheaper and more satisfactory than the Mandler.

J. A. KENNEDY

**Monochromatic light filters. II. Application of the Goldberg spectrodensograph.** E. ELVEGORD, HERBERT STAUDE AND FRITZ WEIGERT. *Z. physik. Chem., Abt. B*, 2, 149-60(1929); cf. *C. A.* 22, 729.

W. F. MEGGERS

**Development of the ultracentrifuge and its field of research.** J. B. NICHOLS. *Colloid Symposium Monograph* 6, 287-308(1928).—A review including: thermodynamical and kinetic applications; solvation and incipient gel formation; proteins. J. A.

**An x-ray tube with detachable ends and electrodes for x-ray spectroscopy.** W. BAND AND A. J. MADDOCK. *J. Sci. Instruments* 6, 160-3(1929).—Directions for constructing a tube with the advantages of the Owen and Preston tube, but which requires the use of a small lathe only. Cf. *C. A.* 21, 343.

J. H. MOORE

**A pyrometer for the measurements of temperatures by means of color changes.** G. NAESER. *Stahl u. Eisen* 49, 464-6(1929).—The compound filter used in the pyrometer can be thought to consist of 3 single filters. The first filter absorbs all except 2 complementary colors, e. g., red and green. The second filter is wedge-shaped and absorbs with increasing thickness more and more red but none of the green; the third wedge-shaped filter absorbs more and more of the green color with increasing thickness, but none of the red. The observer sees a mixt. of the 2 colors, and depending on the thickness of the wedge-shaped filters through which the light rays pass, red or green will predominate. The mixed color, in this case white, will be observed at a place where the intensities of the 2 colors are equal. The change in temp. of the light source changes the place of the mixed color. The filters are of gelatin contg. various org. dyes. The pyrometer is calibrated by means of a radiating black body of known temp. It can be used from 900° to 2000°; the limit of error is  $\pm 13^\circ$ . J. A. S.

**A modified colorimeter for the determination of hydrogen-ion concentration.** J. J. BEAVER. *J. Optical Soc. Am.* 18, 41-9(1929).—A modified Duboseq type colorimeter is described, similar to a standard colorimeter with the addn. of an added cup and plunger, so that there are 2 cups, one above the other, for buffer solns. and a third cup for the unknown. An opal glass plate is placed in the light path to equalize the 2 rays. From the scale reading, when the 2 fields match and the indicator is const., the  $p_H$  is easily calcd. The method is accurate and rapid and can be used with colored or turbid solns.

E. G. VANDEN BOSCHE

**The junior scopometer.** WM. G. EXTON. *J. Am. Med. Assoc.* 92, 708-12(1929).—Description of a simplified app. for measuring, by means of an optical wedge, turbidity and color by the extinction or vanishing point of a target. Cf. *C. A.* 23, 1314, 2331.

J. H. MOORE

**A simple viscometer.** R. A. VAN LINGE. *Chem. Weekblad* 26, 301(1929).—A 50-cc. pipet is provided at the upper end with a two-way stopcock. In one position of the cock the liquid is sucked up into the pipet. A quarter turn closes it. Another quarter turn opens it to the air, allowing the liquid to flow out. The time of delivery is measured by a stop-watch. The temp. is detd. by allowing the liquid, as it is delivered from the pipet, to flow over the bulb of a thermometer.

E. SCHOTT

**An improved simple viscometer for colored fluids.** A. E. ROBINSON. *Ind. Chemist* 5, 205-6(1929).—The improvement is designed to permit the use of the "falling ball" method with colored solns., more particularly with nitrocellulose lacquers. The tube contg. the colored lacquer is fitted at the top with a cap with a hole in the center through which

the ball is dropped. The lower end is closed by a cork or hard rubber stopper to which two or more copper or brass strips are attached and bent so as to catch the falling ball, which then makes contact so that a lamp in the circuit immediately lights. Specifications in detail and a sketch are given.

E. G. R. ARDAGH

**A gravimeter for recording rapid changes of specific gravity in gases.** A. BLACKIE AND B. H. WILLIAMS. *J. Sci. Instruments* **6**, 157-60(1929).—A report is made on favorable attempts to adapt the Ranarex CO<sub>2</sub> recorder to this purpose. Precautions to be observed are given.

J. H. MOORE

**An automatic mercury still.** F. L. ROBESON. *J. Optical Soc. Am.* **18**, 72-4(1929).—A still of Pyrex glass is described. It starts and stops automatically and needs little attention. With 90 w. 100 g. of Hg are obtained per hr.

E. G. VANDEN BOSCHE

**A sublimation mercury still.** K. C. D. HICKMAN. *J. Optical Soc. Am.* **18**, 62-8; *Chemistry and Industry* **48**, 366-9(1929).—An automatic vacuum Hg still, giving about 400 cc. in 24 hrs., is described. Three Pyrex bulbs, blown in the form of an alembic, in series; are utilized for condensation of the Hg. Electrically heated, the Hg is sublimed into a vacuum space allowing no boiling to disturb the liquid surface.

E. G. V. B.

**A still for liquids of high boiling point.** K. C. D. HICKMAN. *J. Optical Soc. Am.* **18**, 69-71; *Chemistry & Industry* **48**, 365-6(1929).—Unstable org. liquids easily oxidized in the presence of air, can be distd. under highly reduced pressure with the app. It consists of an electrically heated still, made in the form of an alembic, so constructed that the surface of the liquid is within a cm. or so of the cooling space.

E. G. V. B.

**Still heads and laboratory rectification columns.** V. LONGINOV AND A. PRYANISHNIKOV. *Trans. Inst. Pure Chem. Reagents (Moscow)* **1929**, No. 7, 54 pp. (Summary in French).—By using an equimol. mixt. of C<sub>6</sub>H<sub>6</sub> and CHCl<sub>3</sub> the efficiency of the Hempel column was studied from the following points of view: (a) height, (b) diam., (c) isolation, (d) rate of distn., (e) reflux ratio, and (f) the nature of the material with which the column is filled. The most important factor is (e). It increases the efficiency 25-63% when the other factors are kept const. Its greatest effect is manifested when the column is isolated, filled with active objects and when the distillation is fast. The factor of next importance is (a). The greatest effect is shown when there is no reflux and when the column is isolated and filled with active objects. (d) and (f) are factors of nearly equal but of secondary importance. The effect of slow distn. is greatest when there is no reflux and when active objects are used. The influence of (f) is greatest when there is a large reflux and when distn. is slow. The influence of (b) is even less and is noticeable only without reflux and with fast distn. The factor of least influence is (c). It is noticeable under the same conditions as (b).

H. F. JOHNSTONE

**A reaction tube.** CHARLES DIHÉRE. *Bull. soc. chim.* **45**, 183-4(1929).—The classical reaction tube described by Hoppe-Seyler is modified in that the cup is maintained in position by three small expansions of the outside tube, instead of by a glass rod reaching to the bottom of the tube.

ALBERT L. HENNE

**Extraction and perforated apparatus for the extraction of liquids.** PAUL H. PRAUSNITZ. *Oesterr. Chem.-Ztg.* **32**, 71-3(1929).—Historical, with references and 8 cuts. Cf. *C. A.* **22**, 4011.

J. H. MOORE

**A portable pH apparatus with microanalytical electrode and saturated calomel electrode.** ARAO ITANO. *Ber. Österr. Inst. landw. Forsch. (Japan)* **4**, 19-26(1929).—The results which are closely comparable with those obtained with the type K potentiometer are obtained with the app. described. The app. is inexpensive and easily carried around, and the cost of maintenance is very low. Each part in the app. is independent so that it can be used separately, if so desired. An electrode for the detn. of the pH value in a min. quantity of sample, 0.02 cc. or less, is described. The results of a comparative study of a 0.1 N electrode and a satd. electrode of special prepn. show very close agreement. The calcd. potential of a satd. calomel electrode was 0.2514 v. at 18°. A photograph of the app. is shown.

E. F. SNYDER

**Labor-saving devices for the commercial protein testing laboratory.** W. O. WHITCOMB. *Cereal Chem.* **6**, 215-17(1929).—Description is given of carriages for holding Kjeldahl flasks, caustic soda buret, acid buret, buret for distd. water and tube for indicator.

L. H. BAILEY

**D. V. L. pressure cylinder and its use.** E. RACKWITZ AND ERICH K. O. SCHMIDT. *Chem. Tech. Rundschau* **44**, 343(1929).—The Deutschen Versuchsanstalt für Luftfahrt has introduced a glass or porcelain cylinder for use in testing corrosion of metals and protective coatings by liquids and gases. The cylinder has a lateral rectangular opening of about 50 × 200 mm. in which the material to be tested is inserted, the cylinder then being filled with the liquid under investigation.

E. PICKERING

**Use of amplifiers for the measurement of small quantities of energy.** J. BRENTANO.

*Z. Physik* **54**, 571–81 (1929); cf. *C. A.* **22**, 4058.—A bridge arrangement of amplifier tubes is described by which direct currents of  $5 \times 10^{-14}$  amp. and potential differences of  $10^6$  v. can be measured.

GEORGE GLOCKLER

**Conveying chemicals with portable loaders.** MARTIN H. KIDDER. *Chem. Markets* **24**, 619–23 (1929).

F. J. C.

**Chemical plants are turning to welded construction.** ALAN G. WIKOFF. *Chem. Met. Eng.* **36**, 352–4 (1929).

E. J. C.

**An improved electrically heated thermostat.** P. VAN CAMPEN. *Z. Elektrochem.* **35**, 265–6 (1929).—A Hg temp. regulator with a vacuum tube relay is described, the regulator being connected in the grid circuit of the tube. Since the operating current through the regulator is only  $10^{-4}$  amp., difficulties with arcing are avoided. A magnetic relay for controlling heater current is also described. The device makes contact by means of an iron U-shaped bar bridging Hg cups; all contacts are placed in an evacuated glass container, troubles from arcing being thus eliminated. Control of a water thermostat to  $0.002^\circ$  is attained.

C. Z. ROSECRANS

**Filter or diaphragm.** SIEMENS & HALSKE A.-G. Fr. 653,033, April 19, 1928. A porous filtering layer or an electrolytic diaphragm is made from oxide of Cr by mixing the oxide with one or more compds. of Cr, e. g., chromic acid,  $\text{Cr}(\text{NO}_3)_3$ , pressing the mixt. into molds and heating until the other Cr compds. are transformed to the oxide. Substances such as NaCl or substances such as sawdust, which are eliminated by heating, may be added before heating.

**Air filter.** ALBERT KRAUTZBERGER. Ger. 476,050, Jan 21, 1928.

**Dust filter for gases.** AUGUSTE J. GAUNE (Fils). Fr. 654,821, May 25, 1928.

**Rotary star filter for separating dust from gases.** MASCHINENFABRIK BUCKAU R. WOLF. A.-G. Ger. 476,762, Feb. 25, 1927.

**Device for determining the quantity of dust in gas currents.** ASKANIA-WERKE A.-G. VORM., CENTRALWERKSTATT DESSAU and CARL BAMBERG. Ger. 475,604, Jan. 15, 1926. The device is particularly applicable to gases contg. coal dust. The passage of the dust-laden gas through an electrically heated tube causes variations in the temp.

**Filter for liquids.** JAKOB GLAUSER-JOST. Swiss 130,409, Feb. 3, 1928.

**Filter for water, etc.** ROBERT D. TACKABERRY. U. S. 1,715,435, June 4. Structural features.

**Filter for water of engine-cooling systems, etc.** MORRIS BASSION. U. S. 1,715,492, June 4. Structural features.

**Oil filter.** AC SPARK PLUG CO. Fr. 654,561, May 22, 1928.

**Vacuum filter for oil, etc.** GASTON J. LIPSCOMB. U. S. 1,716,786, June 11. Structural features.

**Continuous-filter thickening apparatus.** ALBERT L. GENTER (to Genter Thickener Co.). U. S. 1,716,040, June 4. Structural features.

**Apparatus for withdrawing the bottom layers of liquid mixtures.** FRITZ REHMANN. Swiss 130,657, Dec. 13, 1927.

**Steam-heated apparatus for gravity separation of oil and water.** HUBERT J. SMITH. U. S. 1,716,934, June 11.

**Tank with v-shaped bottom for settling solids from liquids.** JAMES Q. HORNE. U. S. 1,716,228, June 4. Structural features.

**Closed rotary drum for clarifying and purifying liquids.** RAMESOHL & SCHMIDT A.-G., JOHANN F. MEYER and HANS LÜCKER. Ger. 476,731, May 27, 1925.

**Dipping refractometer suitable for opaque liquids.** EMIL BUSCH A.-G. Ger. 476,360, June 24, 1927.

**Atomizer.** OSKAR BRANDEIS. Ger. 476,741, Aug. 29, 1926. Water is electrically heated before being forced through the atomizing nozzles.

**Thermometers.** THERMEX SOC. ANON. Ger. 476,684, April 23, 1927. A method of regulating a bimetal spiral thermometer is described.

**Optical pyrometer.** ANSON HAYES. U. S. 1,716,775, June 11.

**Funnel with automatic closing device in the neck.** GOTTFRIED OPPLIGER. Swiss 130,669, Feb. 23, 1928.

**Cathode funnel for mercury-vapor rectifier.** AKTIEN-GESELLSCHAFT BROWN, BOVERI & CIE. Swiss 131,216, Feb. 2, 1928.

**X-ray tube.** ALBERT BOUWERS (to Naamlouze Vennootschap Philips' Gloeilampen-fabrieken). U. S. 1,717,309, June 11. An incandescent filament cathode is used with an anticathode consisting partly of W and hollowed at the focal spot. Various structural details are described.

**Safety device for Röntgen-ray apparatus.** REINIGER, GEBBERT & SCHALL A.-G. Ger. 476,785, Feb. 10, 1924. Details are given.

**Electron tubes.** RADIOWERK E. SCHRACK. Fr. 654,804, May 14, 1928. Arrangements of electrodes are described.

**Electron-discharge tubes.** BENJAMIN F. MIESSNER. Fr. 653,825, May 3, 1928.

**Electron-discharge device.** EMIL G. WIDELL (to Westinghouse Lamp Co.). U. S. 1,716,159, June 4. A device contg. alkali metal has a portion of its envelope adjacent; the leading-in wires are coated with a non-conducting org. material such as shellac or rosin capable of preventing leakage between the leading-in wires. Various other structural details are described. Cf. C. A. 23, 312.

**Anode for electron-discharge devices.** WESLEY F. MASSEY (to General Electric Co.). U. S. 1,717,239, June 11. Structural features.

**Vacuum tube for ultra-violet rays.** NAAMLÖÖZE VENNOOTSCHAP PHILIPS' GLOEI-LAMPENFABRIEKEN. Fr. 653,622, April 30, 1928.

**High-vacuum apparatus comprising condensation vacuum pumps operating in series.** OSKAR SEITZ (to Akt.-Ges. Brown, Boverie & Cie.). U. S. 1,716,507, June 11. Structural features.

**Thermionic electrode.** GEORGE M. J. MACKAY (to General Electric Co.). U. S. 1,716,545, June 11. See Brit. 267,142 (C. A. 22, 1065).

**Thermionic valves.** WILLIAM R. BULLIMORE. Fr. 655,051, May 31, 1928.

**Furnaces.** EUGEN HABER. Ger. 475,693, Feb. 7, 1924. The heat-exchanging structures of a gas heater are built as conducting canals round the main gas canal.

**Furnaces.** ALBERT REPPMAN. Fr. 655,050, May 31, 1928. Construction of an adjustable roof is described.

**Furnaces.** KOHLENVEREDLUNG A.-G. Fr. 653,942, May 7, 1928. Furnaces, particularly for the coking of bituminous products, are heated by hot gases traversing a layer of the product in a direction perpendicular to the direction of movement of the layer.

**Furnaces.** L. and C. STEINMÜLLER. Ger. 475,694, Feb. 11, 1927. Water tubes are arranged in the fire-chamber walls.

**Furnaces.** C. H. WECK KOMM.-GES. Ger. 475,692, Oct. 30, 1925. The furnace has several compressed air chambers and a traveling grate mounted on rollers.

**Automatic furnaces.** RILEY STOKER CORP. Fr. 653,710, May 2, 1928. Method of regulating the air to the surfaces supporting the fuel.

**Annealing furnace.** HEINRICH BANGERT. Fr. 654,698, Jan. 17, 1928.

**Annealing furnaces.** OTTO BASSON. Ger. 476,069, Aug. 19, 1927. Relates to continuously-operating annealing furnaces of the kind in which the goods are lifted from the hearth at intervals and moved forward by eccentrically operated carriers, and describes improvements in the means for operating the carriers.

**Annealing furnace.** SIEMENS-SCHUCKERTWERKE A.-G. Fr. 653,930, May 7, 1928. Cooling means are mounted inside the air-tight envelope of the furnace.

**Tunnel furnace.** HEIMSOOTH & VOLLMER, G. M. B. H. Fr. 654,909, May 26, 1928

**Furnace with trough-shaped fire-chamber bottom.** FRÄNKEL & VIEBAHN. Ger. 476,743, Mar. 19, 1926. Addn. to 438,842.

**Trough-like fire chamber for ovens, drying apparatus and the like.** EMIL GRUND-MANN ERSTE SACHSISCHE PATENT-BACKOFEN- UND PATENT-ARMATURENFABRIK. Ger. 475,691, July 15, 1926. Details are given.

**Coal-dust furnace.** HERMANN BLEIBTREU. Ger. 472,696, Oct. 6, 1926. Addn. to Ger. 446,637. The combustion chamber widens in stages and the burning nozzles are axial and parallel.

**Burners for powdered fuel.** RILEY STOKER CORP. Fr. 654,303, May 14, 1928.

**Burner for powdered fuel.** EWALD HERMSDORF. Ger. 476,224, Mar. 10, 1927. The air-fuel mixt. on its way to the combustion chamber is given a whirling movement by a rotary mixer actuated by a turbine wheel arranged in the path of the mixt.

**Burners for liquid fuel.** PAUL LINKE. Fr. 653,729, Mar. 10, 1928.

**Oil-fuel burner.** FREDERICK HAAGER and GEORGE H. CLARK. Australia 11,061, Dec. 30, 1927.

**Oil burner with fuel feed above and below the burner.** STEAM PRODUCTION CORP. Ger. 475,690, April 26, 1927.

**Burner for vaporized hydrocarbons.** PHILIP H. STEINER. Fr. 653,542, April 27, 1928.

**Safety devices for gas furnaces.** COMP. DES FORGES DE CHÂTILLON-COMMENTRY ET NEUVES-MAISONS. Ger. 476,612 and 476,613, Oct. 7, 1927.

**Mixture regulator for gas furnaces.** LUDWIG STIEGLER. Ger. 476,646, Dec. 10, 1925. Details are given.

**Temperature regulator for gas furnaces.** LE RÊVE S. A. Fr. 653,498, April 27, 1928.

**Gas-furnace burners.** DEUTSCHE WÄRME-AUSNÜTZUNG, G. M. B. H. "DEWAG." Fr. 653,197, Sept. 16, 1927.

**Gas burner.** JOHAN W. BAKHUIZEN. Fr. 654,864, May 25, 1928.

**Gas burner.** JOHN G. CALVERT. U. S. 1,715,989, June 4.

**Gas burners.** LOUIS M. J. GUERPILLON. Fr. 653,451, April 26, 1928. Air-admission regulation is described.

**Gas burners.** COMPAGNIE DES LAMPES. Fr. 33,847, July 6, 1927. Addn. to 584,551.

**Gas burner.** FIRME DEUTSCHE WÄRME-AUSNÜTZUNG, G. M. B. H. "DEWAG." Fr. 654,600, April 26, 1928.

**Gas burners.** IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 653,679, May 2, 1928.

**Gas burner.** GEORGE F. REZNOR. U. S. 1,716,601, June 11.

**Compressed air and gas burner.** DEUTSCHE WÄRME-AUSNÜTZUNG, G. M. B. H. Ger. 476,614, Feb. 23, 1928.

**Regulating device for furnaces for liquid or dust-like fuels.** RUDOLF MEYER. Ger. 475,576, Oct. 7, 1927.

**Means for tapping shaft furnaces.** DEMAG A.-G. Ger. 476,024, Nov. 4, 1928. Addn. to 437,206.

**Furnace wall.** LIPTAK FIRE-BRICK ARCH CO. Ger. 476,175, April 26, 1927.

**Operating device for the traveling grate of a furnace.** BÜTTNER-WERKE A.-G. (Herbert Zikesch, inventor.) Ger. 475,998, Oct. 17, 1925.

**Traveling grate.** WILHELM BERG. Ger. 476,081, Dec. 13, 1927.

**Coal-feed control for trough grates.** ENZINGER-UNION GES. FÜR WÄRMETECHNIK M. B. H. Ger. 476,026, April 6, 1928.

**Hurdles or grates for gas purifiers.** ARTHUR BEUTHNER. Ger. 476,352, Sept. 16, 1928. Addn. to 456,371.

**Movable fuel container for tunnel retort.** JULIUS PINTSCH. A.-G. Ger. 476,661, Sept. 14, 1924. Details are described.

**Oven with rotating annular hearth for heating powdered or finely granular materials in a thin layer.** TROCKNUNGS-, VERSCHWELUNGS-, UND VERGASUNGS-G. M. B. H. Ger. 476,395, Dec. 10, 1927.

**Heating device for laboratory water bath.** HANS VON CHRISTIAN. Swiss 131,048, Feb. 20, 1928.

**Heat regenerators.** VERGASUNGS-INDUSTRIE A.-G. Austrian 112,826, April 15, 1928. The patent describes heat regenerators in which the blow gases of a gas generator are burnt and which are adapted to act as water evaporators. The evapp. chamber is arranged below the combustion chamber.

**Heat-exchange apparatus.** RUDOLPH VUILLEUMIER (to Safety Car Heating & Lighting Co.). U. S. 1,716,333, June 4. Structural features.

**Heat exchanger for heating air.** EUGEN HABER. Ger. 476,262, Sept. 19, 1925.

**Heat exchanger, especially for heating air.** SCHMIDT'SCHE HEISSDAMPF-GES. M. B. H. (Georg H. Davin, inventor). Ger. 476,083, Sept. 28, 1926.

**Apparatus for heating liquids.** ALBERTO E. BIANCHI. Fr. 653,750, April 5, 1928. In an app. for distg. hydrogenating or dehydrogenating liquids such as naphtha, tar, or mazout, the shafts carrying rotating agitators in the vessels heated externally are hollow and connected at their ends to form a worm by which the liquid to be treated is introduced in a continuous manner.

**Drying apparatus.** ERNEST WINDSOR. Ger. 476,783, Oct. 21, 1927. Details are given.

**Drying machine for fibrous materials.** ERICH LAU. Ger. 476,532, Dec. 10, 1927.

**Matrix drying apparatus.** EMIL HAAS and WALTER STUDER. Swiss 131,116, Mar. 8, 1928.

**Distilling column.** MANRY FRÈRES. Fr. 653,576, April 28, 1928. A column is described which may be used either for concg. alcs. to a high degree or for distg. them.

**Fractionating distilling column.** ROBERT E. WILSON, ROGER D. HUNNEMAN, WILLIAM H. BAELKE and FRANCIS M. ROGERS (to Standard Oil Co. of Ind.). U. S. 1,716,939, June 11. Structural features.

**Apparatus for introducing materials into high-pressure vessels, particularly coal into hydrogenation vessels.** CHEMISCHE-TECHNISCHE-GES. M. B. H. (Albert Besta, inventor.) Ger. 476,396, Nov. 18, 1924.

**Rotary vacuum liquid cooler.** FRANZ GOEKE. Ger. 475,940, May 25, 1928. Details of construction are given.

**Apparatus for vacuum concentrating liquids.** PAUL C. LEMALE. Fr. 654,272, Oct. 13, 1927.

**Gas-tight joints for metallic high-vacuum vessels, with a mercury luting.** AKTIEN-GESELLSCHAFT BROWN, BOVERI & CIE. Swiss 130,780, Jan. 14, 1928.

**Gas-tight joints between glass and metal tubes.** CHRIST KIRWER (to Westinghouse Elec. & Mfg. Co.). U. S. 1,716,140, June 4. Structural features.

**Closing device for high-pressure piping.** CHARLES SCHAEER. Swiss 131,175, Feb. 12, 1927.

**Mixing apparatus.** ARCA-REGLER A.-G. Ger. 476,338, July 10, 1928. Mech. regulated app. is described whereby substances of different consistencies are continuously and automatically mixed in a predetd. proportion. Reference is made to the *manuf. of paper pulp* with a predetd. content of water.

**Mixing and agitating apparatus.** CHEM. FABRIK GRÜNAU LANDSHOFF & MEYER A.-G. Ger. 476,181, Oct. 21, 1927.

**Driving means for vibrating classifiers.** WILHELM SELTNER. Ger. 476,208, Mar. 19, 1924.

**Diffusion apparatus for indicating the presence of combustible, explosive or poisonous gases.** BRUNO TREBITSCH. Austrian 112,720, Nov. 15, 1928.

**Apparatus for automatic recording of the analysis of gas containing carbon dioxide.** SOC. ANON. DES ANCIENS ÉTABLISSEMENTS VANHOUTTE ET JUILLOT. Fr. 653,844, May 4, 1928.

**Time and temperature control device for valves supplying heating fluids.** ROY W. BROWN (to Firestone Tire and Rubber Co.). U. S. 1,715,987, June 4.

**Apparatus (utilizing a wheatstone bridge) for comparative heat conductivity tests of gases.** RICHARD H. KRUEGER (to Charles Engelhard, Inc.). U. S. 1,715,374, June 4.

**Apparatus for comparing and registering the intensity of radiant energy.** ARTHUR C. HARDY and FREDERICK W. CUNNINGHAM. Fr. 655,039, May 31, 1928.

**Apparatus for recovering the heat and vapors generated in gas reactions.** GEORGES L. E. PATART. Ger. 476,840, Jan. 22, 1925. Details of arrangement are given.

**Arrangement of tubes to increase the effective area of a surface condenser.** MASCHINENFABRIK OERLIKON. Swiss 130,762, Nov. 29, 1927.

**Fat-removing and cleaning apparatus, especially for hollow bodies.** ANNA W. F. SCHAMMER (NÉE STOLLE) and ANITA H. SCHAMMER-UHLENDORF. Ger. 476,036, Aug. 2, 1927. The bodies to be cleaned are treated with volatile solvents in a rotating or swinging basket surrounded by a system of cooling tubes which may move with the basket or be stationary.

**Fat-removing and cleaning apparatus, especially for hollow bodies.** ANNA W. F. SCHAMMER (NÉE STOLLE) and ANITA H. SCHAMMER-UHLENDORF. Ger. 476,366, Dec. 17, 1926. Addn. to 456,811. The app. is generally similar to that of Ger. 476,036 (cf. preceding abstract) but differs in mech. details.

**Hydrogenation apparatus.** SOC. INTERNATIONALE DES COMBUSTIBLES LIQUIDES (Deutsche Bergin A.-G. für Köhle und Erdölchemie, applicants in Germany.) Fr. 653,135, Apr. 20, 1928. Welding prepn. which resist the attack of hot H under pressure are composed of alloys of Fe with Be, Al, V, Cr, Mo, Mn, Ni or Co or of the metals themselves, or the joints of the app. using hot H under pressure are covered with a layer of one of these metals or an alloy thereof. Fr. 653,136 describes the coating of vessels and pipes of hydrogenation app. with a layer of Cr, Be or Al, which are preferably diffused into the top layer of steel by a heat treatment.

**Rotary acetylene generator with counter-pressure chamber.** RICHARD MÜTSCHLE. Ger. 476,647, May 26, 1926. Details of construction are given.

**Containers for storing gases.** SVENSKA AKTIEBOLAGET GASACCUMULATOR (Gustav Dalén, inventor). Ger. 476,263, Mar. 17, 1925. Containers for storing  $C_2H_2$  and other gases are filled with balls or lumps prepd. from a fibrous, granular or powd. porous material and an adhesive, e. g., from kieselguhr, pumice, asbestos, cellulose, etc., and  $ZnCl_2$ . The balls or lumps may have a core of different porous material, e. g., charcoal. The spaces between the balls or lumps are filled with loose fibrous, granular or powd. material, e. g., kieselguhr.

**Storage tank with a "breather roof" for holding volatile liquids.** HARRY C. BOARDMAN (to Chicago Bridge & Iron Co.). U. S. 1,716,947, June 11. Structural features.

**Automatic vent for "breather roofs" for volatile-oil storage tanks.** CLAYTON L. DAY (to Chicago Bridge & Iron Co.). U. S. 1,716,950, June 11. Structural features.

**Apparatus for dissolving and feeding calcium hydroxide into iron pipes to check corrosion by water, etc.** CHRISTIAN BÜCHER. U. S. 1,716,205, June 4.

**Thermostatic valve for gas burners.** VICTOR MAUCK. U. S. 1,717,052, June 11. Structural features.

**Thermostatic control for valves of gas burners.** GEORGE A. ROBERTSHAW. U. S. 1,715,950, June 4. Structural features.

**Thermostatic control for regulating supply of fuel to burners.** EDWARD L. FONSECA (to Wilcolator Co.). U. S. 1,715,650, June 4. Structural features.

**Thermostatic control device for electric heating apparatus.** LEE P. HYNES (to Consolidated Car-Heating Co.). U. S. 1,717,155, June 11.

**Thermostatic control for apparatus for heating fluids.** VICTOR G. VAUGHAN (to Westinghouse Elec. & Mfg. Co.). U. S. 1,715,687, June 4. Structural features of a thermostatic switch, etc.

**Thermostatically controlled water-heating system.** RICHMOND ROCHESTER, JR. (to Automatic Electric Boiler Co.). U. S. 1,715,512, June 4.

**Thermostatic mixing valve suitable for controlling the mixing of hot and cold water.** WILLIAM B. LASKEY. U. S. 1,715,662, June 4. Structural features.

**Thermostatic control for electric circuits.** HERBERT E. RIDER (34% to Emil Blair, and 18% each to Clinton T. Revere and George C. Shubert). U. S. 1,715,676, June 4. Structural features.

**Thermostatic control for electric appliances.** WILLIAM W. McLAREN. U. S. 1,715,464, June 4. Structural features.

## 2—GENERAL AND PHYSICAL CHEMISTRY

FREDERICK L. BROWNE

**Maximilian Toch.** ELLWOOD HENDRICK. *Ind. Eng. Chem.* **21**, 704(1929).—Biography with portrait. E. C. M.

**Charles Mayer Wetherill, 1825-1871.** I. EDGAR F. SMITH. *J. Chem. Education* **6**, 1076-89(1929). E. J. C.

**Award of American Institute of Chemists (to Mr. and Mrs. Francis Patrick Garvan).** *J. Chem. Education* **6**, 1035-75(1929). **Advance of the nation through the science of chemistry.** CHAS. H. HERTY. Pp. 1037-44. **Chemistry in relation to medicine.** JOHN J. ABEL. Pp. 1045-64. **Pioneers in public service.** JOHN W. DAVIS. Pp. 1065-8. **Presentation address.** JOHN H. FINLEY. Pp. 1069-71. **Acceptance address.** FRANCIS P. GARVAN. Pp. 1072-5. E. J. C.

**Ancient symbols for metals.** JOHN WHITE. *Science Progress* **23**, 687-8(1929).—A relationship is suggested between the alchemical symbols for the metals and the Arabic numerals. JOSEPH S. HEPBURN

**The number of students of chemistry.** F. QUINCKE. *Z. angew. Chem.* **42**, 522-3(1929).—This is an interpretation of statistics from various sources as to the number of students taking chemistry in German institutions, with an attempt to reconcile the discrepancies in such reports. The numbers of students enrolled during the summer semesters of 1911, 1925 and 1928 are as follows: (a) Universities—1524, 3693, 2679; (b) Technical schools (Technische Hochschulen)—1671, 3759, 2497; (c) Pharmacy (in universities)—954, 1505, 742; (d) ditto (in technical schools)—84, 200, 122. (e) Totals of above—4233, 9157, 6040. The increase in the no. of women students is noted specially. W. C. EBAUGH

**The conduct of courses in the teaching of high-school chemistry.** J. O. FRANK. *Science Education* **13**, 211-6(1929). E. H.

**High-school projects in chemistry.** S. D. LAW. *J. Chem. Education* **6**, 1139-43(1929). E. J. C.

**Educational aims in teaching elementary chemistry.** FRANCIS C. COULSON. *J. Chem. Education* **6**, 1120-5(1929). E. J. C.

**Reform in the chemistry curriculum.** R. J. HAVIGHURST. *J. Chem. Education* **6**, 1126-9(1929). E. J. C.

**Improvement of scientific ability through the use of the individual laboratory exercise in chemistry.** RALPH E. HORTON. *J. Chem. Education* **6**, 1130-5(1929). E. J. C.

**International chemistry.** AUSTIN M. PATTERSON. Antioch Coll. *Science* **69**, 531-6(1929).—A sketch of international coöperation in the last 40 years, with special reference to the work of the *Intern. Union of Pure and Applied Chemistry*. The previous

*Intern. Asscn. of Chem. Societies* is briefly described and "dreams of the future" along the lines of international coordination and distribution of chem. literature are discussed.

E. J. C.

**Limitations upon the unification of chemical nomenclature.** ATHERTON SEIDELL. *J. Chem. Education* 6, 720-9(1929).—A report on 84 replies to an inquiry sent to chemists of various countries. About two-thirds think that internat. efforts to reform nomenclature will not arouse chauvinistic or other antagonisms, and favor commissions for the purpose. However, as to unification of names of long-known elements (Fe, Cu, Ag, Au, etc.), only 29 were clearly in favor, while 37 were unreservedly opposed. Individual comments are given. "The results of this inquiry point out clearly that efforts to improve the nomenclature of chemistry must be confined to new names and to the harmonizing of variations in usage which do not conflict with fundamental language differences."

AUSTIN M. PATTERSON

**Some regularities in the periodic system.** D. STRÖMHOLM. *Z. anorg. allgem. Chem.* 177, 303-12(1928).—Even though the principle upon which Mendeleev designed his table, namely, that of arranging the elements periodically as a function of their at. wts., is no longer wholly tenable, such an arrangement is very usable. S., considering later theories, shows that the percentage electron content of the atomic nucleus increases rapidly with increase of at. wt., and that the relation may be expressed as the quotient of the fraction,  $(at. wt./2) : [(at. wt./2) - Z]$ , where  $Z$  is the at. no. of the element in question. This increase in percentage electron content increases in stages, each stage beginning with a decidedly rare element. The second begins with Sc, the third at either Ga or Ge, the fourth at In and the fifth probably with Hf. S. discusses the significance of these stages particularly as to the formation and disintegration of elements, assuming that elements are formed by reactions analogous to those found in a radioactive series.

L. L. QUILL

**The magnetization of single crystals of cobalt.** SEIJI KAYA. *Science Repts. Tôhoku Imp. Univ.*, 1st Series, 17, 1157-77(1928).—Two circular disks, about 4.5 mm in diam. with their planes coinciding, resp., with the 2 principal planes (0001) and (1010) were prepd. from large crystals of Co. In the plane (1010) there are 2 particular directions [0001] and [1010] perpendicular to each other; 1 being the direction of easy magnetization and the other that of difficult magnetization. The parallel and perpendicular components of magnetization in this plane vary with a period of  $180^\circ$ . The satn. value of the intensity of magnetization was found to be 1422 at  $26^\circ$ . D. S.

**A new determination of the melting point of palladium.** C. O. FAIRCHILD, W. H. HOOVER AND M. F. PETERS. *Bur. Standards J. Research* 2, 931-62(1929).—The m. p. of Pd was detd. by measuring with an optical pyrometer the ratio of brightness of the red light ( $\lambda = 0.6528 \mu$ ) emitted by black bodies at the m. ps. of Pd and Au, resp. Of the 2 procedures used, the crucible method in which the pyrometer is sighted into a black body immersed in freezing or melting metal in a crucible was found to be more reliable than the wire method, in which a Lummer-Kurlbaum black-body furnace was employed, the brightness of the black body being measured at the instant a small bit of Au or Pd wire placed inside of the black body and connecting the hot junction ends of a thermocouple melted and halted the e. m. f. of the thermocouple. The temp. of melting Pd was calcd. in terms of that of melting Au by means of Wien's law which is equiv. to Planck's law for light of such wave-length and for such a range of temp. In the computation,  $c_2$  of Wien's law was taken as 1.432 cm. degree and the m. p. of Au as  $1063^\circ$ . The m. p. of Pd was  $1556.6^\circ \pm 1^\circ$ . The av. of this result with those of 6 former detns. is  $1553^\circ \pm 0.7^\circ$ . It is estd. that the uncertainty in this value on the centigrade thermodynamic scale is approx.  $2^\circ$ .

R. J. HAVIGHURST

**A mechanical model of an asymmetric carbon atom.** H. G. TANNER. *J. Phys. Chem.* 33, 755-9(1929).—A description of the construction and functioning of a mech. model of an asymmetric C atom, based on the single postulate that electrodynamic asymmetry of the valence "bonds" is responsible for optical activity.

R. J. H.

**The atomic volume relations in certain isomorphous series.** III. A. F. HALLIMOND. *Mineralog. Mag.* 22, 70-6(1929); cf. C. A. 22, 4411.—Compressibilities of 11 alkali halides can be calcd. from the at. vols. by means of the formula  $\beta = V/K$ ,  $\beta' = V'/K'$ , where  $\beta$  and  $V$  are the compressibilities and at. vols. of the combined metals, resp.,  $\beta'$  and  $V'$  those of the halogens. For the all metals  $K = -4 \times 10^{-4}$ , for the halogens  $K' = -2.5 \times 10^{-4}$ .

W. F. HUNT

**High-temperature experiments. I. Preliminary conditions and materials.** WILLI M. COHN. *Metallwirtschaft* 8, 367-71(1929).—At high temps. stable compds. are rare, the tendency being to split into simpler substances, elements or even at. nuclei with few electrons. Star spectra indicate temps. for their atms. of 3000-30,000°, while

the interiors may be as high as  $40 \times 10^6$ . In high-temp. studies one must have control of the speed of heating, maintenance of a given temp. for a known length of time, production of an oxidizing, reducing or neutral atm., a sufficiently large vol. of heating space, etc. As materials for furnace construction ceramic products, earths, alk. earths, free elements of high m. p., oxides, nitrides and carbides are listed and their phys. properties recorded. From these may be selected materials suitable for working up to temps. of  $3000^\circ$ . By isolating the high-temp. zone from the rest of the app. (as by air layers, vacuum, etc.) higher temps. may be attained.

W. C. EBAUGH

Measurements with the aid of liquid helium. III. Resistance of metals. Superconductivity of tantalum. Contribution to the explanation of superconductivity. Specific heat of gaseous helium. W. MEISSNER. *Z. ges. Kälte-Ind.* 36, 62-8(1929); cf. *C. A.* 20, 3269.—The elec. resistance of various specimens was measured at  $273.2^\circ\text{K}$ . and from  $90^\circ\text{K}$ . to  $1.28^\circ\text{K}$ . In terms of the resistance equal to 1 at  $273.2^\circ\text{K}$ ., the following results were obtained at the lowest temps.,  $1.28^\circ$  to  $1.35^\circ\text{K}$ .: Cu,  $2.9 \times 10^{-4}$ ,  $3.5 \times 10^{-4}$ ; Al, 0.0067; Fe, 0.0103, 0.0141, 0.0163; Be, 0.3077; Co, 0.3632, Mo, 0.1335; Rh, 0.3380; Pd, 0.0245; Ta,  $< 5 \times 10^{-6}$ ; W, 0.0307; Ir, 0.0478; Sb, 0.0239; C, 1.193; nickel silver, 0.8983, 0.9149. Ta was the only specimen showing superconductivity. After measuring the resistance of two like specimens of superconducting Sn, one intimately encased in a nickel silver tube and the other not, it is concluded that the phenomenon of superconductivity is not a surface effect. By a suitable expt. with a four-stage amplifier, no irregularity in the flow of direct current through a sample of superconducting Pb was found. By means of a new precision calorimeter, which is described, the heat capacity of gaseous He at  $5.5^\circ\text{K}$ . and  $0.75^\circ\text{K}$ . is found to be 1.94 cal. per mol.

F. D. ROSSINI

The mechanism of the valve effect at poor contacts. R. AUDUBERT AND M. QUINTIN. *Compt. rend.* 188, 52-4(1929); cf. *C. A.* 22, 533, 1894.—From a theory based on electronic emission and Poisson's equation, an equation representing the valve effect is derived. It agrees with the previous theoretical data. The theory probably explains also the mechanism of AgS and PbS detectors.

ARTHUR FLEISCHER

Calculation of the molecular polarization of dissolved substances at infinite dilution. GUNNAR HEDESTRAND. *Z. physik. Chem.*, Abt. B, 2, 428-44(1929).—The mol. polarization and dipole moment are calcd. for substances dissolved in benzene and hexane, and for glycolcol in water.

F. D. ROSSINI

The measurement of color. F. A. O. KRÜGER. *Z. Ver. deut. Ing.* 73, 465-8(1929).—A modification of the Pulfrich photometer is described whereby it is possible to compare colors and give to them numerical values capable of reproduction. In it the Ostwald factors of basic color, white and black are employed to express the compn. of the sample examd., and illustrations are shown for (a) the numerical values of certain colors, (b) the changes of colors upon weathering and (c) the plotting of results upon logarithmic and 3-component coordinate systems.

W. C. EBAUGH

The solid and liquid phases of helium. W. H. KEESOM. *Natuurw. Tijdschr.* 11, 65-79(1929).—A recent lecture.

J. C. JURRIJENS

Molecular motions in rarefied gases. ERNEST RUTHERFORD. *Engineering* 127, 347-8(1929).—Marked changes occur in the behavior of gases, in passing from ordinary to extremely low pressures. An explanation of this behavior is afforded by the kinetic theory, the essential point being that while at normal pressure, and temp., the mean free path of a mol. is of the order of  $1/100,000$  cm., at pressures corresponding to  $1/100$  to  $1/10,000$  mm. of Hg it becomes comparable with the dimensions of the vessel in which the gas is enclosed. *Ibid* 381.—Expts. indicated that radiometer effects are produced neither at high nor at very low pressures, but only when the mean free path of the mol. is short compared with the dimensions of the radiometer bulb. The phenomena involved are very complicated and have been the object of much study, both theoretical and exptl. *Ibid* 449-50.—The condensation of mols. on a surface produces a complicated problem. A mol. when it strikes a surface does not, in general, rebound at once, but sticks for a little time and then when it does come off, it does so in a direction which is perfectly random and in no way correlated with original direction of incidence. The av. time during which the mol. remains on the surface depends on the abs. temp. The view is now held that mols. which condense on a surface act as a two-dimensional gas. The mols. wander over the surface at random, forming aggregations in the course of time. The d. of the stream of atoms condensing on a surface must attain a certain critical value if a visible deposit is to be formed. Such a visible deposit must be at least three mols. thick.

FRANK V. JOHNSON JR.

The specific heats of some condensed gases between  $10^\circ$  absolute and their triple points. KLAUS CLAUSS. *Z. physik. Chem.*, Abt. B, 3, 41-79(1929).—A vacuum

*calorimeter* for measuring sp. heats of condensed gases down to  $10^\circ$  abs. is described and measurements of  $C_p$  for  $N_2$ ,  $O_2$ ,  $CO$ ,  $CH_4$  and  $HCl$  are given.  $CH_4$  shows a hitherto unsuspected transformation at  $20.4^\circ$  abs. Below  $13^\circ$  the course of the sp.-heat curves is well represented by a *Debye function*. A discussion of the *Pb thermometer* is also given, with tables for the resistance below  $20^\circ$ .

J. B. AUSTIN

**Specific heats of gases at high temperatures.** E. D. EASTMAN. *Bur. Mines, Tech. Paper No. 445*, 27 pp. (1929).—An outline of the methods and results of a study of the most reliable values possible from available data, with an estimate of their accuracy. Earlier investigations are reviewed critically and reasons are given for rejection of some researches purporting to be of high accuracy. Some results are recalcd. from the original data by methods largely eliminating errors characteristic of the methods of measurement. The recalcs. and graphical presentations make apparent the exact contribution of each research and permit independent appraisal of the results. On the side of technic the necessity in sound-velocity work of adequate temp. control and of careful study of tube correction is emphasized.

W. H. BOYNTON

**A new, semiempirical vapor-pressure formula.** VALENTIN KIREV. *Z. Elektrochem.* **35**, 217–20 (1929).—By combining the Clausius-Clapeyron and Nernst equation of state with K.'s empirical formulas for the relation of reduced temps. and pressures, K. derives the equation  $\pi - \ln \pi = m + a (\tau - 1.10 \ln \tau + n)$  where  $\tau$  and  $\pi$  are the reduced temp. and pressure, and  $m$ ,  $n$  and  $a$  are consts.  $a = K_s (1.10 - \tau_s)$  and  $K_s = L_s/RT_s$ ;  $s$  refers to the b. p. and  $L$  to the heat of vaporization. Tables for the values of the functions  $y = x - \ln x$  and for  $y = x - 1.10 \ln x$  are given. The equation holds from pressures above 0.3 atm. to a reduced crit. temp. of 0.85. The calcs. are made for  $C_2H_5OH$  and  $C_6H_6$ .

ARTHUR FLEISCHER

**A vapor-pressure chart for hydrocarbons.** HAL B. COATS and GEORGE G. BROWN. *Univ. Mich. Dept. Eng. Research, Cir. Series No. 2*, 17 pp. (1928).—A new form of vapor pressure chart for hydrocarbons, accurate to  $\pm 0.5^\circ$  over wide ranges of temp., is described. The chart uses straight lines for the vapor pressure of each compd. It was developed by a method based on the fundamental principal that the variations of all properties in the normal paraffin series follow smooth regular curves. A crit. study of existing vapor pressure data was made, and the most reliable were used as a nucleus for the construction of the chart. Curves are given for propane, isobutane, butane, 2-methylbutane, pentane, diisopropyl, 2-methylpentane, hexane, hexamethylene, benzene, 2-methylhexane and heptane.

R. L. DODGE

**The vapor pressure of ethylene chloride between  $-30^\circ$  and  $100^\circ$ .** J. N. PEARCE and PAUL E. PETERS. *J. Phys. Chem.* **33**, 873–8 (1929).—The vapor pressures of ethylene chloride over the temp. range from  $-30^\circ$  to  $100^\circ$  were detd. by a static method. The normal b. p. at 760 mm. was found to be  $84.1^\circ$ , the crit. temp. calcd. to be  $321.9^\circ$ , the molal heat of vaporization at the b. p. 7745 cal. and the molal entropy of vaporization 21.68 cal. Between  $243^\circ K.$  and  $363^\circ K.$  the vapor pressure can be calcd. within 1 mm. by the equation  $\log p = -(4481.12/T) - 52.3092 \log T + 0.071537 - 0.0000418477^2 + 128.756$ .

J. C. McNALLY

**Determination of molecular weights in the vapor state from vapor pressure and evaporation data.** EDWARD W. WASHBURN. *Bur. Standards J. Research* **2**, 703–13 (1929).—Discussion of a method, (cf. *C. A.* **22**, 2693 and 2694) which is based upon detg. at the same temp. the vapor pressure of a substance and the amt. of it required to saturate by aspiration a known vol. of an indifferent gas. The method is applicable to the detn. of the mol. wt. at temps. at which the vapor pressure is small. By employing a reference substance of known mol. wt. the method is practically independent of temp. fluctuations and the measuring of the vol. of gas aspirated can be eliminated.

E. SCHOTTE

**Quantity relations in moist gases.** ROBERT NITZSCHMANN. *Metallbörse* **19**, 958–60 (1929).—Equations and tables designed to shorten calcs. involving moist gases.

W. C. EBAUGH

**Gas-equilibria (homogeneous).** ROBERT NITZSCHMANN. *Metallbörse* **19**, 677–8, 735–6, 790–1, 846–7, 903 (1929).—A series of 282 equations designed to simplify calcs. involving gaseous equilibria.

W. C. EBAUGH

**Volumetric relations of the reaction  $4 HCl + O_2 = 2 H_2O + 2 Cl_2 + 29,400$  cal.** R. NITZSCHMANN. *Metallbörse* **19**, 398–9, 567–8 (1929).—A series of equations, tables and graphs showing values derived from the equation given, under varying conditions.

W. C. EBAUGH

**The volumetric relations of the reaction  $Cl_2 + H_2 = 2 HCl + 44,000$  cal.** R. NITZSCHMANN. *Metallbörse* **19**, 64–5, 176–7 (1929).—A series of 58 equations shows

the results of reactions involving (a) equiv. amts. of  $H_2$  and  $Cl_2$ , (b)  $Cl_2$  in excess, (c)  $H_2$  in excess, but without formation of  $H_2O$ , and (d) ditto but with formation of  $H_2O$ ; and 8 tables give numerical values computed for 6 volume % of  $Cl_2$  in such mixts.

W. C. EBAUGH

**Volumetric and equilibrium relations of the reaction  $CH_4 + H_2O \rightleftharpoons CO + 3 H_2$ .** R. NITZSCHMANN AND H. LIPKA. *Metallhörse* 19, 1014-5(1929). —Equations, tables and illustrative problems.

W. C. EBAUGH

**The decomposition of nitrous oxide in the silent electric discharge. IV. Influence of the addition of foreign gases.** SHRIDHAR S. JOSHI. *Trans. Faraday Soc.* 25, 137-43 (1929).—Measurements were made of the initial velocity of decompn. in mixts. of a const. amt. of  $N_2O$  with varying quantities of  $N_2$ ,  $O_2$  and  $NO_2$  to confirm previous conclusions (C. A. 23, 2887) that the velocity of reaction, the current flowing through and the energy consumed in the ozonizer are related to the amt. of  $NO_2$  present. Added gases cause an increase in  $V_m$  (min. p. d. necessary to initiate decompn.) with increasing electron affinity;  $P$  (mean watts consumed in ozonizer during discharge) diminished.

M. MCMAHON

**The measurement of flame temperatures.** EZER GRIFFITHS AND J. H. AWBERRY. *Proc. Roy. Soc. (London)*, A123, 401-21(1929); cf. C. A. 22, 4340.—Max. explosion temps. were measured in a cylindrical bomb with plate glass ends. Light from an incandescent solid passed through the bomb. Its temp. was adjusted until the  $D$  lines just appeared or did not appear, immediately after the explosion. The temp. could be set within  $10^\circ$  at  $2100^\circ$ . Temp. curves are given for different air-CO mixts. and different gas velocities. The electrodes of an at. H blow pipe were found to be at  $3200^\circ$ , and the gas between them at  $2515^\circ$ .

GERALD M. PETTY

**Combustion of rigidly dried carbonic oxide-oxygen mixtures.** WM. A. BONE. *Nature* 123, 644(1929), cf. Bone, *Ibid* p. 584.—The electrodes were freed from  $H_2$  by glowing *in vacuo* and also in  $O_2$ . A highly purified 2 CO +  $O_2$  mixt., which, under all necessary precautions, has been rigidly dried to the utmost limit possible with redistd. and highly purified  $P_2O_5$ , will still explode and propagate flame provided that a sufficiently powerful igniting spark is used. With Pt-balled electrodes the min. condenser discharge spark required is about 0.75 microlarad at 1000 v. (energy = about 0.75 joule).

G. CALINGAERT

**The temperature relationship of density and refractive index.** W. HERZ. *Z. anorg. allgem. Chem.* 180, 159-60(1929); cf. C. A. 23, 1542.—From  $\alpha = [1/(t_1 - t)] [(d - d_1)/d_1]$  for the temp. coeff. of  $d$ , and  $\beta = [1/(t_1 - t)] [(n - n_1)/n_1]$  for the temp. coeff. of refractive index, the ratio of  $\alpha$  to  $\beta$  for some 23 liquids was investigated; in the calcs. were used temps. of  $8/12 T_k$  and  $7/12 T_k$  and their corresponding values of refractive index and  $d$ . There is no marked similarity in  $\alpha/\beta$ , although for the majority of the substances considered, chiefly org., the range is from 2 to 4.  $S$  and  $H_2O$  are higher, 6.10 and 9.62, resp.

WILLIAM E. VAUGHAN

**Measurements of the refractive index of water between 23 and 73 cm. wave length.** ERNST FRANKENBERGER. *Ann. Physik* [5], 1, 918-62(1929); cf. C. A. 21, 2102.—The app. used is described and illustrated. The refractive index of pure  $H_2O$  remains practically const. in the region of wave length between 23 and 73 cm. Very dil. solns. of  $Na_2Si_2O_5 + 2H_2O$  and  $Na_2SiO_3 + 6H_2O$  from dil. NaOH and colloidal  $H_2SiO_3$  solns. show just as little dispersion as pure  $H_2O$  between 50 and 60 cm. wave lengths. Previous measurements according to the second Drude method have a consistent error due to the surface condition of the wire used.

M. MCMAHON

**Influence of temperature on the expansion coefficient of normal liquids.** K. M. STAKHORSKII. *Ukrainskii Khim. Zhur.* 3, *Sci. Pt.*, 457-62(1928).—From theoretical considerations the following law has been deduced, which expresses the relation between the coeff. of expansion ( $\alpha$ ) and the temp. ( $T$ ):  $\alpha = 0.17 T_{cr}/(T_{cr} - T)$ , where  $T_{cr}$  is the crit. temp. of the liquid. Expts. show that this equation can be used for the temp. interval between the f. ps and the b. ps of the liquids; however, in the vicinity of the b. ps. the const. of the equation is rather 0.18 than 0.17. The equations given by Herz (C. A. 11, 2746) and Kolosovskii (C. A. 21, 1745) present only particular cases of the above equation, which is general. With regard to the applicability of this equation to assoc. liquids, A. Bachinskii has shown (cf. C. A. 5, 1218) that a certain temp. called *metacritical* corresponds to every mol. state of assoc. liquids. The *metacritical* temp. ( $T_{mc}$ ) can be calcd. from S.'s equation by presenting it in this form:  $T_{mc} = T/[1 - (0.17/\alpha T)]$ . The *metacritical* temp. increases with the assocn. factor of the liquid, and both decrease with the rise of temp. The *metacritical* temp. is higher than the usual crit. temp. However, the *metacritical* temp. corresponding to the mol. state of AcOH at the b. p. almost coincides with the usual crit. temp.; this indicates that on

raising the temp. from the b. p. to the crit. point the association factor of  $AcOH$  apparently remains almost unchanged.

BERNARD NELSON

**The molecular theory of non-elastic deformation.** BECKER. *Metallbörse* 18, 709, 765(1928).—A hardened metal, consisting of very small cryst. particles with haphazard orientations, may be considered a sep. phase which differs in free energy from the single-crystal phase by the heat of recrystn. Also its vapor pressure will be higher than that of the single crystal. Recrystn. consists in the formation of large single crystals through the diffusion of atoms from neighboring crystal particles with fortuitous orientation to a "seed" crystal which happens to have a regular structure and a favorable position, and this phenomenon takes place only at temps. so high that diffusion is appreciable.

R. J. HAVIGHURST

**Diffusion in crystallized compounds.** C. TUBANDT, HERM. REINHOLD and WILH. JOST. *Z. anorg. allgem. Chem.* 177, 253-85(1928).—When a direct current is passed through a number of tablets or plates of a salt, the surfaces of which are firmly pressed against each other, no change in the appearance or weight of the individual parts takes place. When different salts touch which contain a common ion, e. g.,  $AgCl$  and  $Ag_2S$  or  $AgCl$  and  $NaCl$  or  $BaCl_2$  and  $BaBr_2$ , an exchange of ions takes place regardless of whether the new salt (formed by substitution) is miscible with the original or not. The extent of this substitution may be detd. very simply by weighing. The method may also be used for purification of the salts without affecting their structure. Similarly the mutual diffusion of 2 salts into each other may be investigated. The velocity of diffusion of the cations was studied in  $Ag_2S$ ,  $AgI$ ,  $AgBr$ ,  $AgCl$ ,  $Cu_2S$ ,  $CuI$  and  $CuBr$ . The diffusion const. of  $Ag_2S$ ,  $Cu_2S$  and  $AgI$  follows the relation  $D = A \cdot e^{-(B/T)}$ . In the case of  $AgI$  and  $CuI$  the diffusion const. may be calcd. from the elec. cond. according to  $D = C \cdot T^{\frac{1}{2}}$ . It is also possible to det. the "autodiffusion" from measurements of cond. and transference in pure salts and mixed crystals.

EMIL KLARMANN

**Electric conductance method for determining liquefaction temperatures of solids.** EDWARD W. WASHBURN and EDGAR R. SMITH. *Bur. Standards J. Research* 2, 787-91(1929).—When a solid or mixt. of solids behaves as an elec. insulator below its liquefaction temp., but becomes a conductor as soon as the liquid phase appears, the temp. at which the system acquires this elec. conductance will be the liquefaction temp. of the system. The app. for detg. this temp. is described. The method is especially convenient when only small quantities of material are available and is unaffected by impurities which do not lower the initial liquefaction temp. It will give reliable results in many cases in which the customary methods fail. Some exptl. data on eutectic temps. of water-salt systems and on transition temps. of salt hydrates are given. E. S.

**Electromotive and elektrokinetic potentials of graphite.** NATHANIEL THON. *Compt. rend.* 188, 253-4(1929); cf. *C. A.* 22, 4330.—Graphite electrodes do not behave like the  $Au$  electrode. The potential increases with increase in concn. of the electrolyte. Graphite functions as a cation electrode. Crystal violet reverses the sign of the electrokinetic potential on graphite.

ARTHUR FLEISCHER

**Adsorption.** RENÉ DUBRISAY. *Rev. sci.* 67, 1-4(1929).—A review. P. T.

**Remarks upon the formulas representing adsorption isotherms.** A. BOUTARIK. *Compt. rend.* 188, 450-2(1929).—By using  $\mu$  the reciprocal of  $\gamma$ , the amt. adsorbed per g. of adsorbent and  $\phi$ , the reciprocal of  $c$  the equil. concn., Perrin's formula simplifies to  $\mu = a\phi + b$ , where  $a$  and  $b$  are consts. By differentiation of Perrin's equation B derives a general equation  $dy/yn = K dc/cn$ : in Perrin's equation  $n = 2$  while in Freundlich's  $n = 1$ . Conclusion: Freundlich's is the simpler equation. A. F.

**The dependence of the adsorption of a dissolved substance on the properties of the solution and solvent.** W. HERZ and L. LORENZ. *Kolloid Z.* 47, 331-4(1929).—A study is made of the adsorption by charcoal of  $I_2$  from its soln. in  $EtOH$ ,  $HOAc$  and various mixts. of  $C_6H_6$  and  $CCl_4$ , and  $C_7H_{16}$  and  $Pr_2O$ . A const. relationship is found between the adsorbability of a substance from org. solvents and their mixts., the soly. of the substance, and the d. and viscosity of its satd. soln. This relationship depends upon the nature of the solvent. R. I. RUSH

**Adsorption from aqueous solutions by silica.** F. E. BARTELL and YING FU. *J. Phys. Chem.* 33, 676-87(1929).—Hydrolytic adsorption occurs when aq. salt solns. are treated with pure dehydrated  $SiO_2$  prepd. from  $SiCl_4$ . The basic constituent is preferentially adsorbed from such solns. In general, bases are adsorbed, org. acids are slightly adsorbed, and inorg. acids are not adsorbed at all. Inorg. bases are preferentially adsorbed in the order  $LiOH > NaOH > KOH > NH_4OH$ . This order is the same as that for the degree of hydration of the cations. The order of adsorption is probably due to the strongly hydrophilic nature of the  $SiO_2$ . Org. acids are adsorbed in decreasing amts. in an ascending homologous series, i. e., formic > acetic > propionic > butyric.

This order is more pronounced in adsorption from org. solvents. From solns. of Na salts of the org. acids hydrolytic adsorption (preferential adsorption of base) occurs in increasing amts. in the ascending homologous series, *i. e.*, Na formate < Na acetate < Na propionate < Na butyrate. Inasmuch as an equil. condition exists between the base adsorbed and the acid in soln., the extent of base adsorption is regulated by the acid given to the soln. by the hydrolytic adsorption, *i. e.*, by the strength of the acid or H-ion concn. of the soln. This probably accounts for the higher degree of hydrolytic adsorption with salts of org. acids than with salts of inorg. acids. The adsorption of inorg. salts such as KCl by  $\text{SiO}_2$  is completely hydrolytic; that is, no KCl as such is adsorbed, neither is Cl ion nor HCl adsorbed. The degree of adsorption is detd. not only by the sp. properties of adsorbent and adsorbate, but is dependent on the soly. of solute in the solvent and upon the solid-liquid interfacial tension relationships. If the soly. of a given adsorbate is the same in a series of different solvents, greater adsorption will occur from solns., the solvent of which has the lower adhesion tension with the adsorbent.

A. WHITE

**Adsorbing power and vapor pressure of adsorbed water by acidic, neutral and alkaline earths.** H. ISOBE. *Bull. Inst. Phys. Chem. Research* (Tokyo) 7, 1133-59; *Abstract sect. 1*, 106-9(1928).—The adsorption of moisture by the earths, "Sansei-Hakudo" from Osawa in Odo, was measured by a relative method. Neutral earth is a better adsorber than alk. or acid earth. Some vapor-pressure curves are given.

G. B. TAYLOR

**The adsorption of water, ethyl alcohol, ethyl acetate and acetic acid by tungstic and zirconium oxides; its bearing on heterogeneous catalysis.** J. N. PEARCE AND M. J. RICE. *J. Phys. Chem.* 33, 692-704(1929).—The adsorption of  $\text{H}_2\text{O}$ ,  $\text{EtOH}$ ,  $\text{AcOH}$  and  $\text{AcOEt}$  vapors by W and Zr oxides was studied at  $99.4^\circ$ . The results are compared with those of a similar study of the adsorption of the same vapors by  $\text{ThO}_2$  and  $\text{Al}_2\text{O}_3$ . For unit vol. of adsorbent the adsorption capacities for  $\text{H}_2\text{O}$  vapor decrease in the order Th, Al, W and Zr oxides. This is also the order of the dehydrating power of these oxides toward alc. The order of adsorption for  $\text{AcOEt}$  is exactly the reverse of that for  $\text{H}_2\text{O}$  vapor. The results confirm the view that in the catalytic process both the alc. and  $\text{AcOH}$  vapor must be adsorbed simultaneously. Further, that the catalytic effect increases as the power of the oxide to adsorb  $\text{H}_2\text{O}$  decreases.

A. WHITE

**The adsorption of iodine, bromine and various halogen salts by carbon in some organic liquids.** JOSEPH TRIVIDIC. *Rev. gén. colloïdes* 7, 14-22(1929); *cf. C. A.* 22, 2092, 2700.—The adsorption of I by C in org. solvents obeys Freundlich's formula rather than that proposed by Davis and Schmidt. The adsorption curves for a series of liquids pass through a common point characteristic of the C and of the series under consideration. Binary mixts. of org. solvents obey the Freundlich equation. A relation exists for these mixts. between the fixed I and that retained in the pure liquids. This also holds for Br. It appears impossible to obtain decisive data on the adsorption of alkali halides by C because of the feeble adsorption possessed by C. I. **Effect of time on the adsorption of iodine by carbon in some organic solvents.** *Ibid* 22-4.—Two preps. of C activated with  $\text{ZnCl}_2$  were used throughout the work. Adsorption work was studied in the following liquids: Me, Et, Pr, isopropyl, Bu, isobutyl, and isoamyl alcs.,  $\text{C}_6\text{H}_6$ , toluene, xylene,  $\text{CCl}_4$  and  $\text{CHCl}_3$ . Contrary to the results of Davis (*C. A.* 2, 221) the adsorption of I is complete after 30 mins. II. **Adsorption of iodine in some organic liquids. Verification of the rule of Freundlich.** *Ibid* 67-73.—In addn. to the above liquids the following were studied: ethylene chloride, ethylidene chloride,  $\text{C}_2\text{H}_5\text{Cl}$ ,  $\text{C}_2\text{HCl}_3$ , mixts. of  $\text{C}_6\text{H}_6$  and  $\text{C}_7\text{H}_8$ , and of  $\text{CHCl}_3$  and  $\text{CCl}_4$ . Freundlich's rule was verified.

RAYMOND H. LAMBERT

**Rapid method for determining maximum adsorption of activated charcoal.** H. BURSTIN AND J. WINKLER. *Przemysl Chem.* 13, 114-9(1929).—On the basis of earlier work, which is here reviewed, a relationship is derived between max. adsorption ( $A_{\text{max}}$ ) and heat of wetting  $Q$  for the system: activated charcoal-benzene, *vis.*  $A_{\text{max}} = KO$ . This relationship is confirmed experimentally by a newly developed practical method for measuring heat of wetting which gave  $K = 1.9\%$  cal. A specimen vacuum flask with a ground-in calibrated thermometer served as the calorimeter. It is a fundamental requirement of this method that the calorimeter, C, and benzene should all be at the same temp., about  $20^\circ$ , at the beginning of the expt. Ten cc. benzene is delivered from a calibrated pipet into the calorimeter flask and the app. is allowed to come to a const. temp. by shaking it  $1\frac{1}{2}$  min. Two g. of activated C, previously dried at  $105^\circ$  is then introduced, the vessel shaken vigorously  $1\frac{1}{2}$  min., and then the temp. rise is read off. Heat of wetting  $Q$  is calcd. from this temp. rise and heat capacities of the materials and app. previously measured.  $A_{\text{max}}$  is measured by passing dry air satd.

with benzene over a weighed quantity of the C to const. wt. and is expressed in  $\frac{g}{g}$ . This method is expected to give good results also for other systems, e. g., activated C, heptane, silica gel-water, etc.

A. C. ZACHLIN

**The relation between the ability of activated charcoal to adsorb electrolytes and the kind of gas with which it is charged.** I. B. BRUNS AND A. FRUMKIN. *Z. physik. Chem.*, Abt. A, **141**, 141-57 (1929).—Ash free sugar charcoal, made by charring recrystallized sucrose in quartz or Pt dishes and then heating the resulting C in a rotating porcelain tube to 1000°, behaves as a gas electrode when placed in solns. of electrolytes; the adsorption of acid or base by such charcoal results from the formation of an elec. double layer at the C-liquid interface. The sign of the charge at the C surface is detd. by the nature of its gas content. Thus, active C after exposure to air adsorbs acid strongly from 0.01 N HCl soln., but adsorbs no KOH from 0.01 N KOH. C cooled in H<sub>2</sub> adsorbs markedly less acid than an air-satd. sample; it likewise adsorbs no KOH. Small percentages of Pt in the activated C enhance the effect produced by charging with H<sub>2</sub>. A C contg. 0.16% Pt adsorbs no acid if satd. with H<sub>2</sub>, whereas it adsorbs acid strongly if satd. with air. Similarly an air-satd. Pt contg. C adsorbs no KOH from 0.01 N KOH, whereas a H<sub>2</sub>-satd. C adsorbs KOH strongly. By its catalytic activity, the Pt present in the C is believed to assure the complete removal of the O<sub>2</sub> content of the C by H<sub>2</sub>. The approx. amt. of adsorption from a given concn. of acid soln. was the same for HCl, H<sub>2</sub>SO<sub>4</sub> and H<sub>3</sub>PO<sub>4</sub>. The amt. of adsorption from acid solns. increased with increasing initial concn. of the acid. The adsorption of benzoic acid from a 0.01 N soln. was independent of both the Pt content of the C and the nature of the gas contained therein. Approx. calcn. of the surface area of a sample of C gives a value of the order of 500 sq. m., of which 0.37 sq. m. only is estd. as covered by a 16% Pt content. The very marked influence of so small a quantity of Pt is regarded as analogous to *promoter action in catalytic reactions*. A discussion of the probable electrode potential of such gas-charged C electrodes is given. II. R. BURSTEIN AND A. FRUMKIN. *Ibid* 158 66.—Ash free C was heated to 1000° in H<sub>2</sub> and its adsorptive activity toward various electrolytes measured without again exposing it to air or O<sub>2</sub>. Samples thus prepd. and tested adsorbed 0.066 milliequiv. of KOH per g. of C from 0.01 N KOH; no HCl was adsorbed from 0.01 N HCl. On the other hand, a g. of the same C when contaminated with air manifested just the reverse ability, adsorbing 0.14 milliequiv. of HCl from 0.01 N HCl but no KOH from 0.01 N KOH. Adsorption of fumes of SO<sub>2</sub> from gas burners in the laboratory was found to decrease the adsorptive efficiency of the C toward the electrolytes. The rate of desorption of adsorbed HCl from C is much faster in a stream of circulating H<sub>2</sub> than in a stream of either N<sub>2</sub> or N<sub>2</sub> and O<sub>2</sub>. App. and technic for prepg. a C sample and testing its adsorptive capacity out of contact with air are described.

P. H. F.

**The behavior of outgassed activated carbon toward electrolytes.** R. BURSTEIN AND A. FRUMKIN. *Z. physik. Chem.*, Abt. A, **141**, 219-20 (1929); cf. preceding abstr.—Ash free sugar C, after being evacuated to  $10^{-5}$  mm. at 1000° for several hours, was found to adsorb neither HCl nor NaOH from dil. solns. of the 2 compds. The same material after exposure to air adsorbed 0.140 milliequivs. of HCl from a 0.01 N HCl soln.

P. H. F.

**Statistical description of the size properties of non-uniform particulate substances.** T. HATCH AND S. P. CHOATE. *Harvard Eng. School, Publ.* No **35**, 369-87 (1928-29). An attempt is made to define particle size by means of well-known statistical methods and to indicate mathematical laws of relationship between particle size, thus defined, and certain size properties of non-uniform particulate substances, namely, number of particles per g. of material and sp. surface of substance. Bibliography. E. I. S.

**Preparation of colloidal solutions.** A. BOUTARIC. *Rev. sci.* **67**, 33-8 (1929).—A review.

P. THOMASSET

**The structure of colloids in the solid state.** J. DUCLAUX. *Rev. gén. colloïdes* **7**, 9-14 (1929).—Colloids may assume different structures in the solid state depending on the mode of prepn. As an example the structure of nitrocellulose is cited. An entirely new form may be prepd. in the presence of cinnamic acid which may be called cellular and which is found to dry very slowly in air. This characteristic resembles certain living tissues.

RAYMOND H. LAMBERT

**Properties of dielectrics and the structure of hydrophilic colloids.** NEDA MARIN-ESCO. *Compt. rend.* **187**, 718-20 (1928).—The inductance capacity of a hydrophilic colloid may change in consequence of adsorption in the same way as that of H<sub>2</sub>O when an electrolyte is added. Dielec. satn. should occur when a micelle is entirely surrounded by H<sub>2</sub>O. Calcd. values of levulose dissolved in H<sub>2</sub>O for dielec. const. as a function of concn. agree well with observed values. Application has been made to methemoglobin, sol. starch

and gum arabic. The dispersing medium plays an important role in the structure of the hydrophilic micelle. The thickness of a  $\text{H}_2\text{O}$  envelope about methemoglobin micelle of radius equal to  $27 \times 10^{-8}$  cm. is calcd. to be  $70 \times 10^{-8}$  cm. R. H. LAMBERT

**The morphology of chemical reactions in colloidal medium.** M. S. DUNIN AND F. M. SHEMAKIN. *Kolloid-Z.* **47**, 335-41(1929).—Satd. solns. of various electrolytes were dropped on 5% gelatin contg. an electrolyte at different concns. The electrolytes used were  $\text{AgNO}_3$ ,  $\text{K}_4\text{Fe}(\text{CN})_6$ , and  $\text{CuSO}_4$ . When  $\text{AgNO}_3$  is the outer electrolyte and  $\text{K}_4\text{Fe}(\text{CN})_6$  the inner, radiating rosetts are formed in the diffusion field. The concn. of the cyanide most favorable is 0.05-0.01  $N$ . No rosetts are obtained if  $\text{AgNO}_3$  is the inner electrolyte. When the concn. of the inner electrolyte is 0.5-0.25  $N$ , concentric layers are formed only under the drops. Radiating rosetts are also formed in the diffusion field when  $\text{CuSO}_4$  is the outer electrolyte and  $\text{K}_4\text{Fe}(\text{CN})_6$  the inner at concns. of 0.05-0.01  $N$ . When the concn. of the inner electrolyte is 0.25-0.05  $N$  well-formed deposits of microscopic layers are formed under the drops. The morphological individuality of the reactions depends to a large extent on the gelatin used. R. I. RUSH

**The reactions between colloidal silica and lime.** PIERRE JOLIBOIS AND LOUIS CHASSEVENT. *Compt. rend.* **188**, 452-4(1929). When solns. of silica and lime are mixed and allowed to stand, the ppt. formed is due to a coagulation of the silica by the lime. This ppt. then slowly combines with the Ca forming a hydrated Ca silicate. The Ca remaining in soln. if highly concd. may continue to be adsorbed by the ppt. for several months. AMY LEVESCONTE

**The influence of agitation on the rate of coagulation of colloids.** K. JABLČZYŃSKI AND G. SZAMES. *Bull. soc. chim.* **45**, 206 10(1929).—When dialyzed  $\text{Fe}_2\text{O}_3$  hydrosol is coagulated with KCl, agitation at first increases the speed of coagulation and then decreases it. With undialyzed  $\text{Fe}_2\text{O}_3$  sol agitation decreases the speed of coagulation. Also in *Roczniki Chem.* **9**, 335-9(339, French) 1929. A. L. ELDER

**Emulsions and suspensions.** ALAN A. CLAFLIN. *Am. Dyestuff Reprtr.* **18**, 277-81 (1929). A general discussion giving elementary definitions and homely examples. The possibilities and applications of the colloid mill are considered. S. K. FORD

**Information on emulsions. I. The influence of soap concentration in both phases on the action of an emulsion.** J. WEICHHERZ. *Kolloid-Z.* **47**, 133-6(1929).—Oil-water and water-oil emulsions stabilized by soap are discussed. Emulsions form on increasing the concn. of soap in water added to oil. On diln. of such oil emulsions with water a critical phase vol. ratio is reached at which the phases reverse and oil in a water emulsion is obtained which depends on soap concn. Expts. are reported with tetralin- $\text{H}_2\text{O}$ , paraffin oil- $\text{H}_2\text{O}$  and xylene- $\text{H}_2\text{O}$  emulsions. The amt. of soap required varied from 0.1 to 8.0% of the oil. Whether oil or  $\text{H}_2\text{O}$  dissolves the soap or soap micelles are absorbed has not been decisively detd. RAYMOND H. LAMBERT

**Ultra-filtration and its industrial application.** G. GÉNIN. *Chimie & industrie Special No.*, 168-74(Feb., 1929).—A review of the properties and prepn. of ultra-filtrating membranes and of their lab. and com. applications. A. PAPINEAU-COUTURE

**The preparation of collodion membranes.** J. BOESEKEN AND O. MEYER. *Rec. trav. chim.* **48**, 504 7(1929).—Collodion membranes were impregnated with  $\text{Cu}_2\text{Fe}(\text{CN})_6$ , and were found to retain dextrans almost completely while permitting some reducing sugars to dialyze. Mol. wts. of 5340-5780 were obtained for the dextrin. T. H. C.

**Solvents and gel formation.** FELIX HEBLER. *Farben-Ztg.* **34**, 1841-3(1929).—Gels may be formed by the swelling of "xerogels" or by the loss of solvent from sols. The properties of gels formed by these two methods are usually different. Suspensions of wax in different liquids, while possessing different working properties, could not definitely be differentiated by their Engler viscosities. G. G. SWARD

**Some properties and theories of gels.** EMIL HATSCHKE. *Chemistry & Industry* **48**, 389-99(1929); cf. *C. A.* **22**, 2093. —Gels are "transparent or translucent bodies contg. a considerable fraction of liquid, but maintaining their shape and exhibiting rigidity." Gels are of 4 types; (1) heat reversible gels like gelatin, (2) irreversible gels like  $\text{SiO}_2$ , which are ineptly called "inelastic" because on drying they become porous instead of shrinking, (3) gels which are an unstable, transient stage in crystn. like azomethine and  $\text{MnHAsO}_4$ , (4) gels, like collodion, formed by displacement of the dispersion medium by a miscible, but non-solvent liquid. The elastic properties of (1) and the appearance of double refraction when stressed are reviewed. Little study has been made of the elastic properties of (2) except that their rigidity, resulting in audible vibration, has been observed and when stressed they are found not to be doubly refracting. The behavior of gels of type (2) on drying has been studied and the size of the pores in the xerogels measured. The properties of types (3) and (4) have received very little study. Gas bubbles forming in gels are lenticular in shape; in the sol imme-

diately before gelation they are spherical. "A single theory of gel structure is not likely to explain the great diversity of behavior exhibited by a few typical gels, though on the other hand every theory of a single example will have to explain some features common to all." H. holds that gels are 2-phase systems, that at least in many gels one phase is solid, and that a fibrillar structure is indicated. F. L. BROWNE

**Solubility of silver in water.** H. KŘEPELKA AND F. TOUL. *Collection Czechoslov. Chem. Comm.* 1, 155-64(1929).—The soly. of metallic Ag in water (cf. Hönigschmid and Birckenbach, *C. A.* 16, 860) is detd. by nephelometric and e. m. f. methods. In the latter method, the set-up consisted of the cell,  $\text{Ag-H}_2\text{O-satd. KCl-Hg}_2\text{Cl}_2$  in  $N$  KCl-Hg, a ballistic galvanometer being used as the null instrument (cf. Beans and Oakes, *C. A.* 15, 8). The soly. at  $20^\circ$  reaches a max. of about 0.036 mg. per l. in about 21 days. Since no Ag dissolves in water from which air and  $\text{CO}_2$  have been carefully excluded, soln. is due to direct oxidation to  $\text{Ag}_2\text{O}$ . The soly. is slightly higher in glass vessels than in Ag, probably because of the alkalies dissolved from the glass. J. H. REEDY

**The aqueous solution of cupric and ferrous sulfates.** F. K. CAMERON AND H. D. CROCKFORD. *J. Phys. Chem.* 33, 709-16(1929).—Detns. at  $30^\circ$  showed that the solubilities of  $\text{CuSO}_4$  and  $\text{FeSO}_4$  in  $\text{H}_2\text{O}$  are each depressed by addn. of  $\text{H}_2\text{SO}_4$ . Soly. of either  $\text{CuSO}_4$  or  $\text{FeSO}_4$  in  $\text{H}_2\text{O}$  is depressed by the presence of the other and increasingly so if  $\text{H}_2\text{SO}_4$  is present. The behavior is explained by assuming the solid phases  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  and solid soln. of  $\text{FeSO}_4$ ,  $\text{H}_2\text{SO}_4$  and  $\text{H}_2\text{O}$ . M. MCMAHON

**The systems butyl alcohol-water and butyl alcohol-acetone-water.** DAVID C. JONES. *J. Chem. Soc.* 1929, 799-813.— $\text{BuOH}$ ,  $d_{44}^{20}$  0.81417 and  $n_D^{20}$  1.39711, was used to det. the binary soly. curve with  $\text{H}_2\text{O}$  to approx.  $-20^\circ$ . The crit. soln. concn. is 32.4%  $\text{BuOH}$  and the crit. soln. temp. is at  $124.75^\circ$ . The ternary system  $\text{BuOH-Me}_2\text{CO-H}_2\text{O}$  was studied to det. the effect of a 3rd component. The  $\text{Me}_2\text{CO}$   $b_{760}$  56.3°. The soly. curve was detd. by the synthetic method for the mixts. made up by wt. As the concn. of  $\text{Me}_2\text{CO}$  increases the crit. line falls slowly from the binary crit. soln. temp. and then increasingly steeply to  $-15^\circ$ . Mutual solvents as alc. and  $\text{AcOH}$  examined gave the same results as  $\text{Me}_2\text{CO}$ . In all cases the ternary crit. soln. temps. are more sensitive to impurities than the binary. I. A. KOTEN

**The densities of butyric acid-water mixtures.** JOHN GRINDLEY AND CHARLES R. BURY. *J. Chem. Soc.* 1929, 679-84.—The results confirm the suggestion of Jones and Bury (*C. A.* 22, 341), that micelle formation occurs in butyric acid solns. It is argued that micelle formation must lead to abrupt changes in the slope of phys. property-compn. curves. The densities of butyric acid-water mixts. were detd. at  $0^\circ$ ,  $12^\circ$ ,  $18^\circ$ ,  $25^\circ$  and  $34.94^\circ$ . The partial sp. vols. of the 2 components were evaluated by the graphical method of Hildebrand. Ds. were detd. according to Hartley and Barrett (*C. A.* 5, 2996) with a modification of their formula and the use of a flask of the type used by Baxter and Wallace (*C. A.* 10, 303). The d. of pure butyric acid over the range studied is given by  $d_4^{20} = 0.97844 - 0.001004t + 2.5 \times 10^{-7}t^2$ . As expected, there is an abrupt change in the slope of the curve at a concn. of about 15% acid. I. A. K

**Osmosis of ternary liquids.** G. A. H. SCHREINEMAKERS. *Chem. Weekblad* 26, 306-14(1929).—See *C. A.* 23, 1536. J. C. JURRIENS

**Osmotic pressures of acetone solutions.** M. J. MURRAY. *J. Phys. Chem.* 33, 896-920(1929).—Attempts were made to measure osmotic pressures with acetone as a solvent and rubber sheets as semipermeable membranes. The permeability of the rubber for the solutes used— $\text{H}_2\text{O}$ ,  $\text{NaI}$ ,  $\text{KI}$ , succinic, malic, tartaric and citric acids—made the results of the expts. uncertain but it is concluded that the osmotic pressures of acetone solns. would agree with those predicted by the gas laws if the exptl. errors were lower. J. G. McNALLY

**Isotonic liquids.** F. A. H. SCHREINEMAKERS. *Rec. trav. chim.* 48, 393-401(1929).—When two aq. solns. are sep'd. by a membrane permeable to  $\text{H}_2\text{O}$  only, a quantity  $\gamma$  of  $\text{H}_2\text{O}$  diffuses through the membrane toward the soln. with the higher osmotic water attraction,  $\xi$ , and the decrease in the thermodynamic potential of the total osmotic system is  $(\xi - \xi')\gamma - C\gamma^2$ . The 2 solns. are isotonic with respect to  $\text{H}_2\text{O}$  when  $\xi = \xi'$  and no  $\text{H}_2\text{O}$  passes through the membrane. For a binary soln. of  $X$  in  $W$  there is only one concn. at which the soln. is isotonic with some given soln., but for a ternary soln. of  $X$  and  $Y$  in  $W$  there are an infinite no. of concns. that are isotonic. For any soln.,  $\xi$  depends not only on the concn. but also upon the temp. and pressure. The pressure coeff. of  $\xi$  is  $d\xi = [-V + x(\delta V/\delta x) + y(\delta V/\delta y)]dP = -\Delta V \cdot dP$ . The temp. coeff. of  $\xi$  is  $d\xi = [H - x(\delta H/\delta x) - y(\delta H/\delta y)]dT = \Delta n \cdot dT$ .  $x$  and  $y$  are the mol. fractions of solutes  $X$  and  $Y$ ,  $V$  is the vol.,  $H$  the entropy of 1 mol. of soln.,  $P$  pressure and  $T$  temp. When  $P$  and  $T$  both change  $d\xi = -\Delta V \cdot dP + \Delta n \cdot dT$ . Two solns. may be isotonic at one temp.

only and the direction of movement of  $H_2O$  through the membrane differs above and below that temp. Two solns. with the same f. p. are isotonic only at that temp. Analogous rules may be stated for pressure instead of temp., reading vapor pressure for f. p. Two solns. with the same osmotic pressure,  $\pi$ , are isotonic only at the pressure  $1 + \pi$  atm.; solns. isotonic at 1 atm. pressure have different osmotic pressures. Two isotonic solns. remain isotonic if temp. and pressure change thus:  $(\Delta V - \Delta V')dP = (\Delta\eta - \Delta\eta')dT$  where  $\Delta V$  is the change in total vol. and  $\Delta\eta$  the change in entropy when soln. is mixed with 1 mol. of  $H_2O$ . For very dil. solns. (1) if the solns. are isotonic at any given  $T$  and  $P$ , they are also at other temps. and pressures, (2) the concn. alone det. whether the solns. are isotonic, (3) isotonic solns. have the same f. p., vapor pressure and osmotic pressure, and (4) solns. with the same f. p., vapor pressure and osmotic pressure are isotonic. Two solns. are isotonic with respect to a solute  $X$  when they have the same osmotic  $X$  attraction.

A. J. MONACK

**A new application of the differential ebullioscope.** W. SWIETOSLAWSKI. *Compt. rend.* 188, 256-8(1929).—The app. previously described may be used to study liquids which form azeotropic mixts. The differences in temp. of the liquid and vapor are noted at various pressures.

ARTHUR FLEISCHER

**Conductivity of a solution of lead and ammonium nitrate.** G. MALQUORI. *Atti accad. Lincei* [6], 9, 231-3(1929).—In a previous paper (*C. A.* 22, 3852) the authors by a study of the solubilities of the compds. in each other's presence, indicated the possibility of the formation of a *complex salt*. This hypothesis is strengthened by a study of the cond. of the solns. The conductivities of the individual salts when plotted, show a straight-line increase, but with both present there is a break in the curve, which further indicates a complex formation. It is probable that a complex ion of the type  $Pb(NO_3)_4^{--}$  is present.

A. W. CONTIERI

**Investigations of carbohydrates. I. Conductivity of binary salts in ethyl chloride.** P. WALDEN AND G. BUSCH. *Z. physik. Chem., Abt. A*, 140, 89-123(1929).—With  $EtCl$  as solvent, precise cond. measurements were made up to a diln. of 400,000 at  $0^\circ$ ,  $25^\circ$ , and  $50^\circ$  of  $Et_4N$  picrate,  $Et_4NCl$ ,  $Et_4NClO_4$ ,  $Et_4NI$ ,  $Me_4N$  picrate,  $Me_4NClO_4$ ,  $Me_4NI$ , etc. Phys. measurements of dielec. const., both of salt and solvent, as well as viscosity measurements were made. The Kohlrausch-Debye-Huckel square-root law for the trend of cond. with concn. was found valid for high dilns.; with decreasing dielec. const. this is transformed to the Walden equation  $\epsilon \sqrt{c} = \text{const.}$  for high dilns. The salt-like character of the substances studied has an important bearing on the cond. at a given diln. The degree of disocn. of the cation is found to be in the order  $N(CH_3)_4^+ < N(C_2H_5)_4^+ < N(C_3H_7)_4^+ < N(C_4H_9)_4^+$  Kohlrausch's law for the additivity of the conductivities is shown to be applicable with  $EtCl$  as solvent. The general Walden rule  $\lambda \cdot \infty \eta = \text{const.}$  is also found to hold.

H. R. MOORE

**Electrolytic polarization. VII. Complex cyanides: (a) silver.** SAMUEL GLASSSTONE. *J. Chem. Soc.* 1929, 690-702; cf. *C. A.* 19, 1228.—The cathode potentials and current efficiencies for Ag deposition were measured in a no. of argentocyanide solns. and the results discussed. The influence of stirring, temp. and diln. were investigated. It is shown that the argentocyanide probably dissociates very rapidly. Existing theories of the deposition of Ag from cyanides are shown to be unsatisfactory and a new theory involving a complex cation is proposed. The effects of Na, K and  $CO_3$  ions on the form of the Ag deposit are discussed. **Complex cyanides: (b) copper.** *Ibid* 702-13.—Electrometric titration of  $CuCN$  and soly. measurements in alkali cyanide solns. show that the complex ions  $Cu(CN)_2^-$  and  $Cu(CN)_3^{--}$  can both exist. The cathode potentials and current efficiencies for Cu deposition were measured. The effects of raising the temp. and of stirring were investigated and shown to be in harmony with the view that cuprocyanide ion dissociates rapidly. The difference in behavior of Cu and Ag in complex cyanide solns. is shown to be connected with the fact that a small increase in the ratio cyanide : metal ions with Cu raised the electrode potential to a point at which the evolution of  $H_2$  is possible.

LOUIS WALDBAUER

**Calcium-amalgam electrode in dilute aqueous solutions.** RUSSEL J. FOSBINDER. *J. Am. Chem. Soc.* 51, 1345-56(1929).—F. redetd. the activity coeffs. of  $CaCl_2$  from 0.01 to 3.3  $M$  and obtained values which agreed up to 1.0  $M$  with those of Lucasse (*C. A.* 19, 1365). A suitable app. was devised for the detn. of the activity coeffs. of Ca ions, by means of which their values were detd. in aq. solns. of  $CaSO_4$ , Ca lactate,  $Ca(OH)_2$ ,  $CaCl_2$  and Ca acetate for concns. between 0.01 and 0.001  $M$ . It was impossible to use the Ca electrode for the detn. of Ca activities in physiol. solns. The potential is lowered in the presence of cations either above or below Ca in the electromotive series and likewise by the presence of protein.

H. S. v. KLOOSTER

**The problem of dilution in colorimetric hydrogen ion measurements. I. Isohydric indicator methods for accurate determination of  $p_H$  in very dilute solutions.** EDNA H. FAWCETT AND S. F. ACREE. *J. Bact.* **17**, 163-204(1929).—A study of the diln. curves for the different buffers and media investigated reveals 3 types of variation from the electrometric  $p_H$ ; (1) buffer diln. effects, (2) changes caused by varying  $CO_2$  and by alk. impurities in the water used, and (3) differences in  $p_H$  valued of the indicator solns. The effect of  $CO_2$  is not marked until a diln. of 1 to 50 is reached; it then increases markedly with diln.; in the case of buffer  $p_H$  5 water often carried the curves beyond the range of the indicators used.  $CO_2$  acts not only as an acid but also as a buffer. The adjustment of the buffer soln. itself does not begin to make noticeable changes in readings until a diln. of 1.100 is reached in org. media, or molalities of 0.00001 to 0.000083 in synthetic media. The isohydric indicator method makes possible colorimetric salt error corrections and  $p_H$  measurements to about 0.1  $p_H$  by the use of indicators adjusted at their mid point  $p_H$  for buffers at the usual concns. and up to 50-fold diln. If adjusted at their lowest, mid point, and highest useful  $p_H$  values the method can be used from 50- to 100-fold diln. of buffer solns. If adjusted at intervals of 0.1 or 0.2  $p_H$  the method can be used for extreme dilns. where q. m. f. detns. are inaccurate or useless. A bibliography is included. JOHN T. MYERS

**Copper oxide in the borax bead.** WILDER D. BANCROFT AND R. L. NUGENT. *J. Phys. Chem.* **33**, 729-44(1929); cf. *C. A.* **23**, 2868. —The change of blue to green in the Cu borax bead is due to reduction of  $Cu^{++}$  to  $Cu^+$ . The green of Cu glasses is due to a mixt. of  $Cu^{++}$  and  $Cu^+$ . The blue given to glass by CuO deepens with increasing amt. of alkali and at low temps.; increasing Cu content in the borax bead with high temps. changes the color from light blue to deep green. The behavior of CuO in glazes is considered. A critical bibliography is included. M. McMAHON

**Elliptical polarization produced by reflection at the surface of fatty acid solutions in water.** CH. BOUDET. *Compt. rend.* **188**, 59-61(1929); cf. *C. A.* **21**, 3312. —Measurements of the elliptical polarization of the fatty acids from acetic to myristic were made covering the entire range of concn. where satd. solns. were not formed. As the no. of C atoms increases the tendency for a min. in the curve increases. The ellipticity is a function of the concn. The orientation of mols. in the pure org. acid is not the same as that in the soln. of min. ellipticity. ARTHUR FLEISCHER

**Study of ionic equilibria. III. Equilibrium of cadmium sulfide and dilute hydrochloric acid.** MAURICE AUMERAS. *J. chim. phys.* **25**, 727-42(1928); cf. *C. A.* **21**, 3009; **22**, 529. —The equil. was studied by pptg. 0.1 N  $CdCl_2$  with 0.1 N  $H_2S$  and detg. the amt. of N HCl just able to dissolve the  $CdS$ . The consts. for the various equilibria were calcd. by the law of mass action. For the reaction  $CdS + 2HCl = H_2S + CdCl_2$ ,  $K = 1.06 \times 10^{-6} = [CdCl_2][H_2S]/[HCl]^2$ . This value is an arithmetic mean of those found by Bruner and by Zawadzki by other methods. Depending on whether Walker and McCormack's or Auerbach's value for the soly. product of  $CdS$  at  $18^\circ$  is used, the secondary dissoen. const. of  $H_2S$  is 0.59 or  $0.37 \times 10^{-15}$ . KNOX found  $1.2 \times 10^{-15}$ . ARTHUR FLEISCHER

**The effects of salts on weak electrolytes. III. Interaction of certain weak electrolytes.** HENRY S. SIMMS. *J. Phys. Chem.* **33**, 745-54(1929). —Previous expts. (*C. A.* **22**, 3815; **23**, 21) are extended to the interaction of weak electrolytes. Glycine causes a drop in  $P_{K'}$  of  $H_2PO_4$  which increases with addn. of the salt; the presence of  $Na_2HPO_4$  increases  $P_{K'}$  of glycine.  $Na_2SO_4$  produces a similar effect on glycine as does  $Na_2C_2O_4$ , Na succinate and Na citrate in concns. up to 0.2  $\mu$ . In more dil. soln. (0.01  $\mu$ ) these 3 latter salts decrease  $P_{K'}$  of glycine. Similar effects were observed for  $P_{K'}$  of succinimide. M. McMAHON

**Action between copper salts and glycerol.** B. K. VAIDYA. *Nature* **123**, 414(1929). —A vigorous action occurs when a soln. of any Cu salt (hydrated or dehydrated) in glycerol is heated to about  $150-200^\circ$ . The salts with the exception of  $CuCl_2$  are decomposed into metallic Cu and free acid, which may undergo further decompn. Glycerol yields  $C_2H_5OH$ , acrolein,  $CO_2$ ,  $CH_4$ , CO and  $H_2$ .  $CuCl_2$  yields  $Cu_2Cl_2$ . Other polyhydric alcs. (glycol, erythritol and mannitol) give nearly the same result. Some of the decompn. products may be due to the catalytic decompn. by finely divided Cu. The action may be represented by  $C_6H_{10}O_6Cu_3 \rightarrow 3Cu + 3CO_2 + CH_4 + C_2H_6$ . The Cu so produced is good for catalytic purposes. GEO. GLOCKLER

**The oxidation of benzoyl-*o*-toluidine at a benzene-water interface with special reference to the temperature coefficient of the reaction rate.** LOUIS S. KASSEL AND NORWOOD K. SCHAFFER. *J. Am. Chem. Soc.* **51**, 965-74(1929). —The oxidation of benzoyl-*o*-toluidine by  $KMnO_4$  at a  $C_6H_6-H_2O$  interface was measured and found to depend upon the rate of stirring and upon the presence of some unknown catalyst. The temp.

coeff. of this rate does not appear to be 13, as reported by Bell (cf. *C. A.* **22**, 3085), but is about 2. It increases somewhat with the temp., indicating that more than one reaction is occurring. The mechanism suggested by Bell, impact of  $\text{MnO}_4^-$  ions on an adsorbed film of benzoyl-*o*-toluidine, does not agree with the data. Other possible mechanisms are suggested.

R. L. DODGE

**Reactions with very large apparent temperature coefficients.** LOUIS S. KASSEL. *J. Am. Chem. Soc.* **51**, 1136-45(1929).—The exptl results of Topley and Hume (cf. *C. A.* **22**, 4036) on the temp. coeff. of the rate of dehydration of  $\text{CaCO}_3 \cdot 6\text{H}_2\text{O}$  crystals can be accounted for by assuming stepwise reactions, all but the last one being reversible. It is unlikely that the dehydration is a single reaction with a temp. coeff. of 12. The anomalous temp. coeffs. of reaction rates in the decompn. of bornyl and menthyl sulfonate solns. (cf. *C. A.* **23**, 128) can be accounted for on the basis of autocatalysis by the resulting acids.

R. L. DODGE

**The theory of molecular dislocation applied to homogeneous catalysis.** J. BÖESCH-KEN. *Trans. Faraday Soc.* **24**, 611-20(1928); cf. *C. A.* **22**, 2307. — Since the Friedel and Crafts reaction is too complicated for a study of the several catalytic actions involved, that of the change of white P into red due to the presence of I was chosen for study. A distinction is made between physical and chemical catalysis. The change of activity of the mol. is named *dislocation* and is considered as elec. in nature. The polymerization of acetaldehyde is an example of dislocation. This action of catalysts is believed to be an induction of the open polar character of the bond between mols. Inhibition occurs if the catalyst is bound too closely so as to form a new non-polar system. In bi-mol. reactions the catalyst causes dislocation in both mols; this is an important factor in the choice of a catalyst. A thermodynamic treatment is given of the dislocation with respect to photooxidation of primary into secondary alcs. under the influence of certain ketones. The supposition is made that in phys. catalysts the  $A$  term of the Arrhenius equation relating temp. and reaction const. remains unchanged the  $B$  term being enlarged, while for chem. catalysis the  $A$  term always increases.

RAYMOND H. LAMBERT

**Homogeneous catalysis. II. Intermediate addition compounds and chain reactions.** J. A. CHRISTIANSEN. *Trans. Faraday Soc.* **24**, 714-15(1929).—In the general discussion on homogeneous reactions C. agrees that a definite chem. mechanism of oxidation and inhibition occurs up to a certain point but some assumption of a chain mechanism must be incorporated to explain exptl. facts.

RAYMOND H. LAMBERT

**Report on the theory of chain reactions.** J. A. CHRISTIANSEN. *Trans. Faraday Soc.* **24**, 596-601(1928).—Factors in certain equations expressing bimol. reactions are discussed. The effect of traces of foreign substances apart from a catalytic action may be neglected. Negative catalysis is not necessarily due to breaking of the chain by foreign material, since hydration produces a like effect. The method of calcn. is equiv. to the method of stationary velocity used in kinetics and is advantageous in the case of negative catalysis where very small concns. of active intermediate products are strongly influenced by the inhibitor.

RAYMOND H. LAMBERT

**The inhibition of chain reactions by bromine.** M. POLÁNYI. *Trans. Faraday Soc.* **24**, 606-11(1928).—Admixt. of  $\text{Br}_2$  for arbitrarily shortening the chain in chain reactions has been studied since  $\text{Br}_2$  inhibits by reacting with free H atoms or  $\text{CH}_3$  radicals. An inherent inhibition influences chain length markedly for small concns. of  $\text{Br}_2$ . For greater  $\text{Br}_2$  concns. alkali bromide is formed, being thereby lost to the induced reaction. Inhibition slightly decreases with increase in temp. in the reaction  $\text{H}_2 + \text{Cl}_2$ ; this is due possibly to  $\text{Br}_2$  catalysis. Alkali metals can be replaced by other metals or even metalloids for the inductive effect as evidenced by a series of bivalent metals. The primary process for Zn takes place according to the reaction  $\text{Zn} + \text{Cl}_2 = \text{ZnCl} + \text{Cl}$  while for Cd the inductive part is less than 1 so that the reaction  $\text{Na} + \text{Cl}_2 = \text{NaCl} + \text{Cl}$  proceeds much faster than  $\text{Cd} + \text{Cl}_2 = \text{CdCl} + \text{Cl}$ . The inductive effect depends on  $\text{H}_2$  pressure and  $\text{N}_2$  admixt. both increasing the effect. The heat of activation is, in these cases, found to equal the heat of reaction for monochlorides of the type  $\text{M}^+ + \text{Cl}$ . Cd and Zn do not in general combine with  $\text{Cl}_2$  to form the normal dichloride but form a monochloride and free Cl atom since  $5 \times 10^3$  collisions can take place between Zn and  $\text{Cl}_2$  before formation of dichloride while  $10^5$  must occur in the case of Cd.  $\text{Br}_2$  does not inhibit formation of HCl but exerts a slight acceleration, while the induced reaction does occur for  $\text{CH}_4$  and  $\text{Cl}_2$ .

RAYMOND H. LAMBERT

**The mechanism of inhibition in autoxidation reactions.** HANS L. J. BÄCKSTRÖM. *Trans. Faraday Soc.* **24**, 601-5(1928).—A study was made of the relation between inhibition and induced reactions which appears to throw some light on the mechanism by which reaction chains may be broken by an inhibitor. The oxidation of sulfite

solns. in the presence of alcs. was chosen for the reaction. Isopropyl, *sec*-butyl and benzyl alcs. were tried as inhibitors. The activity of the alc. in breaking the chains was proportional to its concn. and its relative inhibitory power. For a mixt. of two alcs. oxidation was proportional to the alc. concn. and the relative inhibitory powers. Results were identical whether started thermally or photochemically. Induced or "photosensitized" oxidation of alc. obeys Einstein's photochemical equivalence law. Cu catalysis accelerates the total reaction without changing the ratio of sulfite oxidized to alc. oxidized, *i. e.*, without altering the chain length. RAYMOND H. LAMBERT

The influence of nitrogen peroxide on the combination of hydrogen and oxygen. H. W. THOMPSON AND C. N. HINSHELWOOD. *Proc. Roy. Soc. (London)*, **A124**, 219-27 (1929); cf. *C. A.* **22**, 3816.—The effects of the pressure, temp. and nature of reaction vessel on the combination of  $H_2$  and  $O_2$  in the presence of  $NO_2$  were studied and a theory of chain reactions involving the formation of  $H_2O_2$  is given and discussed.

MALCOLM DOLE

Activity of various catalysts in promoting the oxidation of methane by means of oxygen. JOHN R. CAMPBELL. *J. Soc. Chem. Ind.* **48**, 93-7T (1929).—Hydrolysis of  $MeMgI$  gave  $CH_4$ ; this was mixed with 0.5 vol. of  $O_2$  and stored over satd.  $MgCl_2$  soln. The mixt. was circulated over 20 cm. of hot catalyst at a rate of 50 cc. per min. for 5 hrs. by means of a Sprengel pump. Products were partially removed from the gas by washing with 5 cc. of ice- $H_2O$ ; at the end of the oxidation, the gas pressure was noted and the compn. calcd. by the method of Bone and Wheeler (*J. Chem. Soc.* **83**, 1074). The wash-water was tested for  $H_2CO$ ,  $HCO_2H$  and  $MeOH$ . The following catalysts were used: Ag (I) from ignition of  $AgNO_3$  and reduction at  $500^\circ$ ; Cu (II) from  $Cu(NO_3)_2$  at  $400^\circ$ ; V oxides (III) from  $NH_4VO_3$ ; Pt-asbestos (IV) from  $(NH_4)_2PtCl_6$ ; and Pt- (V) and Pd-black (VI) reduced on asbestos by means of  $H_2CO$ . I, II and III were made up with 1 g. of catalyst on 12 g. of 8-32 mesh pumice; IV, V and VI contained 0.027 g. of metal on 3 g. of asbestos. Tables and curves show the  $CH_4$  oxidized between  $0^\circ$  and  $700^\circ$ . I and II became active at about  $320^\circ$ , and I gave a complete reaction at a lower temp. ( $610^\circ$ ) than II or IV. III became active at  $480^\circ$  and gave a complete consumption of  $O_2$  at  $580^\circ$ , which was lower than I, II or IV, the latter becoming active, however, at  $430^\circ$ . V and VI induced reaction at room temp.; V causing total consumption of available  $O_2$  at a temp. about  $100^\circ$  above VI. The following gives the decreasing order of efficiency of the catalysts: VI, V, III, I, IV and II.  $H_2$  was produced with I and III, probably from the decompn. of  $H_2CO$ , otherwise  $H_2CO$  was the only intermediate product detected in the wash- $H_2O$  aside from a small quantity of  $HCO_2H$  in the case of III. The presence of a catalyst did not seem to change the course of the oxidation as proposed by Bone, but varied the stages so that intermediates were not easily isolated.

A. S. CARTER

Catalytic decomposition of carbon monoxide. I. Iron as catalyst. HIROSHI TUTIVA. *Sci. Papers Inst. Phys. Chem. Research (Tokyo)* **10**, 69-82 (1929). (In Esperanto.)—The decompn. rate of CO was measured in presence of C, of 2 kinds of Fe wire, of reduced Fe and of a mixt. of  $Fe_3C$  and C, and the carbons produced were studied with x-rays. Conclusions: (1) Fe itself functions not as a catalyst but as a catalyst donor, *i. e.*, as a supporter of autocatalytic decompn. of CO. (2) When CO decomposes in presence of Fe,  $Fe_3C$  forms first and the two reactions,  $3Fe + 2CO = Fe_3C + CO_2$  and  $2CO = C + CO_2$  progress concurrently. (3)  $Fe_3C$  has a remarkable catalyzing ability and plays a chief role in the decompn. of CO. (4) C isolated from the catalytic decompn. not only has no catalyzing power but even hinders the catalytic effect of  $Fe_3C$ . (5)  $Fe_3C$  becomes very densely packed with the C which is itself isolated by decompn., till it ceases completely to catalyze. On this account  $Fe_3C$  in the C is very difficultly removable. This suggests a quality of C which is obtained catalytically by decompn. in presence of metal. (6) "X-carbide" of U. Hofmann is Fe oxide.

AUSTIN M. PATTERSON

Study of the action of iron catalyzers on mixtures of carbon monoxide and hydrogen. E. AUDIBERT AND A. RAINEAU. *Ann. combustibles liquides* **3**, 367-428 (1928).—See *C. A.* **23**, 2094.

R. E. SCHAAD

The autocatalytic decomposition of thiosulfuric acid. II. K. JABLONCZYŃSKI AND S. FRENKENBERG. *Bull. soc. chim.* **45**, 210-7; *Roczniki Chem.* **9**, 327-34 (334 in French) (1929); cf. *C. A.* **21**, 1215.—The rapidity of the decompn. of  $H_2S_2O_3$ , as measured by the relative opacity of the soln., was greatly increased by preliminary addn. of a suspension of colloidal S from previous runs, approx. in proportion to the amt. added. Addns. of com. powd. S or of mastic also increased the rate but not so markedly.

T. H. CHILTON

Catalytic effects in concentrated salt media. M. BOBETSKY AND D. KAPLAN.

*Z. anorg. allgem. Chem.* **177**, 119–23 (1928).—The analytical method suggested in *C. A.* **22**, 3816 is developed further. For the investigation, there is required only a half cc. of the soln.; this is mixed with 30 cc.  $\text{H}_2\text{C}_2\text{O}_4/\text{H}_2\text{SO}_4$  soln. The app. employed is the same as in the earlier work. To 15 cc. of a soln. 0.2 *N* in oxalic acid and *N* in sulfuric acid add 15 cc. of 2.5 *N* salt soln. and finally 0.5 cc. of inductor soln. Adjust the temp. of the mixt. to 5° (plus or minus 0.1° tolerance) and add from a second vessel at the same temp., 0.5 cc. of 0.01 *N*  $\text{KMnO}_4$  and stir. Det. the time of decolorization by a stop watch. The results are interpreted through the assistance of tables, and conditions of acceleration and retardation of the velocity of decolorization are set forth through mathematical formulas taken in connection with the tables. B. HAMILTON

**Catalytic oxidation of naphthalene.** TOKISHIGE KUSAMA. *Bull. Inst. Phys. (Chem. Research (Tokyo))*, **7**, 1087–1132, Abstract sect. 1, 105–6 (1928).—Acidic oxides are the best promoters for  $\text{V}_2\text{O}_5$  as catalyst in the oxidation of naphthalene to phthalic acid. A theory is presented that basic oxides including lower *V* oxides combine with the acid produced.  $\text{H}_2\text{O}$  vapor tends to yield benzoic acid. G. B. TAYLOR

**Investigations on the one-component system silica. III. Stability regions of quartz, tridymite and cristobalite.** C. J. VAN NIEUWENBURG. *Rec. trav. chim.* **48**, 402–5 (1929); cf. *C. A.* **22**, 2863.—The samples of cristobalite and tridymite were prepd. by mixing quartz with the proper amt. of  $\text{LiCO}_3$  soln. and evapg. to dryness so 1% of the catalyst was present. After heat treatment the samples were washed with dil.  $\text{HCl}$  and distd.  $\text{H}_2\text{O}$  and dried at 60–70°. The thermal dilatation diagram was worked out from these samples. The stability regions of quartz, tridymite and cristobalite as described by Fenner (*C. A.* **7**, 3945) were confirmed. It was proved that cristobalite cannot be formed from the vapor phase and that amorphous  $\text{SiO}_2$  results. Below about 1300° quartz is always a transitory decompn. product of cristobalite. In the course of 6 to 20 hrs., depending on the temp., the quartz is changed, evidently into tridymite. There is a very clear irregularity in the expansion of tridymite at temps. varying from 430° to 480°, but neither a very sensitive thermal analysis nor a study under the polarizing microscope showed the slightest discontinuity at 450°. The question of whether or not a fourth enantiotropic modification of tridymite really exists is left open.

**Binary system alumina-silica.** VEADIMIR ŠKOLA. *Chem. Obzor* **4**, 112–7 (1929) (117 English).—The heterogeneous binary system  $\text{Al}_2\text{O}_3\text{--SiO}_2$  is very complicated because both  $\text{Al}_2\text{O}_3$  and  $\text{SiO}_2$  exist in various heteromorphous forms. The different relationships are illustrated by the diagrams of Fenner, Parkin-Shepherd-Wright and Bowen-Greig. The *manuf. of artificial corundum and sillimanite* according to Malinowsky, Lecesne-Gowen and Goldschmidt is described and the high content of  $\text{Al}_2\text{O}_3$  for the good qualities of ceramic materials is emphasized. J. KUČERA

**Compound formation in ester-water systems.** JAMES KENDALL AND LILIAN E. HARRISON. *Trans. Faraday Soc.* **24**, 588–96 (1928).—An examn. was made of data obtained on the f.-p. depression and soly. for aq. solns. of the following esters: Me propionate, Pr formate, Et formate, Me acetate, and dimethyl oxalate with data also on Et acetate. Low soly. is closely related to small internal pressure. Internal pressure differences cause abnormally small f.-p. depression while compd. formation produces abnormally large depression. Dimethyl oxalate shows the greatest neg. deviation in f.-p. depression. Little differences are observed where the alc. radical is the only variable factor. Compd. formation is connected with acidic strength of acid radical. Speed of ester hydrolysis is also dependent on this latter property. A further study is to be made of this phenomenon. RAYMOND H. LAMBERT

**Critical solution-temperature phenomena in the ternary system phenol-thymol-water.** KATHLEEN W. WILCOX AND C. R. BAILEY. *J. Phys. Chem.* **33**, 705–8 (1929).—The liquid-liquid equil. is examd. by the synthetic method. Data and curves are given for the binary system thymol-water and for the ternary system phenol-thymol-water. R. J. HEMPHILL

**Ammonium sulfite and bisulfite. I. Solubility and transition point of ammonium sulfite.** F. ISHIKAWA AND H. MUROOKA. *Bull. Inst. Phys. Chem. Research (Tokyo)* **7**, 1160–76, Abstract sect. 1, 110–1 (1928); cf. *C. A.* **23**, 2642.—Equil. in the system  $(\text{NH}_4)_2\text{SO}_3\text{--H}_2\text{O}$  was measured at –13 to +100°. Transition from  $(\text{NH}_4)_2\text{SO}_3\text{·H}_2\text{O}$  to  $(\text{NH}_4)_2\text{SO}_3$  occurs at 81°. G. B. TAYLOR

**The reduction of cuprous oxide by carbon monoxide.** CHAS. G. MAIER. *Bur. Mines, Repts. of Investigations*, Ser. 2926, 7 pp. (1929).—The presence of less than 0.1 mm.  $\text{CO}$  pressure in an atm. of otherwise pure  $\text{CO}_2$  will act reducingly towards  $\text{Cu}_2\text{O}$  below 1064°. The equil. changes with temp. in such a way that below 900° decreasing quantities of  $\text{CO}$  suffice to reduce  $\text{Cu}_2\text{O}$ . At temps. near and above the m. p. of  $\text{Cu}$

a partial pressure of 7.6 mm. CO in otherwise pure CO<sub>2</sub> should reduce the dissolved CuO to 0.008%.

**The dependence of the surface tension  $\gamma$  and the heat of vaporization  $\lambda$  on density and temperature, up to the critical temperature.** J. J. VAN LAAR. *Z. anorg. allgem. Chem.* **180**, 193-214(1929).—A theoretical treatment yields the equation  $\gamma = 0.4362 f \alpha d_1 (d_1 - d_2)^2 p_k \sqrt{v_k/N}$ , where  $f$  and  $\alpha$  are consts.,  $d_1$  and  $d_2$ , resp., densities of liquid and vapor;  $p_k$  is crit. pressure;  $v_k$ , crit. vol.; and  $N$ , Avagadro's no. A test with benzene and ether gives  $\alpha = 0.2537$  and  $0.2502$ , resp. The agreement is fair considering the large temp. range (10° to 280° for benzene), but not startling. The law of Dutoit and Friderich is derived theoretically. Heat of vaporization and mol. surface energy and their relationship with  $d$  and temp. are also treated mathematically.

WILLIAM E. VAUGHAN

**Calculation of latent heats of vaporization of hydrocarbons and alcohols.** J. W. SCHULTZ. *Ind. Eng. Chem.* **21**, 557-9(1929).—If, for a liquid, the Dühring line and the entropy of vaporization at 2 or 3 temps. is known, the latent heat of vaporization can be calcd. for other temps. The method has been applied to 4 hydrocarbons and 2 alcs for temps. nearly up to the crit.

### 3—SUBATOMIC PHENOMENA AND RADIOCHEMISTRY

S. C. LIND

**Fine structure of absorption edges of x-rays.** B. B. RAY AND P. C. MAHANTI. *Z. Physik* **54**, 534-6(1929).—See *C. A.* **23**, 3158.

GEORGE GLOCKLER

**Synthesis of the elements.** G. I. POKROVSKII. *Z. Physik* **54**, 724-30(1929). cf. *C. A.* **23**, 2879.—The energy of nuclear synthesis in interstellar space is assumed to come from the combination of a proton and an electron with emission of a quantum. The resulting velocity of the proton may carry it into the nucleus. The mass defects of the elements are calcd. and the curve obtained agrees with Aston's (cf. *C. A.* **21**, 3543).

GEORGE GLOCKLER

**Synthesis of the elements in the stars.** R. D'E. ATKINSON AND F. G. HOUTERMANS. *Z. Physik* **54**, 656-65(1929).—The notion of Gamov (*C. A.* **23**, 2352) that a probability exists for the disruption of a nucleus by the emission of an  $\alpha$ -particle gives

the idea according to von Laue (C. A. 23, 1565) that the inverse process also can take place. A. and H. find that in the interior of stars protons can enter the nucleus of lighter elements;  $\alpha$ -particles cannot. The heavier elements are also considered.

GEORGE GLOCKLER

**Optical concentration measurement of atoms and ions.** W. DE GROOT. *Z. Physik* 55, 52-5(1929).—The influence of the broadening of the emission line caused by self absorption on the concn. measurements by optical means is discussed (cf. C. A. 22, 910).

GEORGE GLOCKLER

**Matter and light as two different phases of the same material.** W. ANDERSON. *Z. Physik* 54, 433-44(1929).—Matter (protons and electrons) and light (quanta) become identical at high pressure.

GEORGE GLOCKLER

**An isotope of oxygen, mass 18.** W. F. GIAUQUE AND H. L. JOHNSTON. *J. Am. Chem. Soc.* 51, 1436-41; *Nature* 123, 318(1929).—The weak doublets of the atm. absorption bands of  $O_2$  originate from a mol. consisting of an O atom 16 and one of 18 or  $O_{16}O_{18}$ . Some results of band analysis are given and it is claimed that no other isotope of O combined with an atom of O of weight 16 will satisfy the data. The data show that the normal state of the  $O_2$  mol. has one-half units of vibration in agreement with the wave-mechanic theory.

GEORGE GLOCKLER

**Density and shape of submicroscopic particles.** G. PLACZEK. *Z. Physik* 55, 81-118(1929).—From the behavior of an uncharged metallic particle in an inhomogeneous field it is possible to get some idea of its spherical shape and the compactness of its structure. Expts. are carried out on oil drops, Ag and Hg. The problem relates to questions concerning Millikan's oil-drop method of detg. the charge of an electron.

GEORGE GLOCKLER

**Determination by electrical means of  $\alpha$ -particles.** G. ORTNER AND G. STETTER. *Z. Physik* 54, 449-76(1929).—The various methods used in the detection and the detn. of  $\alpha$ -particles and other corpuscular rays are discussed. The use of amplifiers which magnify the ionization currents due to the  $\alpha$ -rays is especially studied on Ra C.

GEORGE GLOCKLER

**Some experiments on the multiple scattering of  $\alpha$ -particles.** D. C. ROSE. *Proc. Cambridge Phil. Soc.* 24, 557-66(1928).—Expts. have been made on the scattering of  $\alpha$ -particles by surfaces on which radioactive material had been deposited and on surfaces in the neighborhood of the source in an attempt to raise the effective strength of the source by including particles which were scattered out of the surface at glancing angles. The effect was found to be too small to be of importance. A repetition of the Lawson and Hess expts. (cf. C. A. 14, 146) on the scattering of  $\alpha$ -particles by the walls of a long glass tube down which a beam of particles was projected indicated that the particles may lose any fraction of their energy in the scattering. It was also indicated that the probable angle of scattering in such expts. is large, and that the av. particle spends at least half and probably a greater fraction of its range in the scattering material.

J. B. AUSTIN

**New species of fast  $\beta$ -rays.** D. SKOBELEZIN. *Z. Physik* 54, 686-702(1929).—In a Wilson cloud chamber there appeared  $\beta$ -ray tracks due to electrons produced by cosmic rays.

GEORGE GLOCKLER

**Determination of radium content using the  $\gamma$ -rays.** V. A. SOKOLOV. *Z. Physik* 54, 385-98(1929).—The  $\gamma$ -ray method for the detn. of Ra is as accurate and more convenient than the  $\alpha$ -ray or emanation methods. A  $\gamma$ -ray electroscope with a sensitivity of  $2 \times 10^{-10}$  g. Ra per g. of substance is described (cf. C. A. 16, 4130).

GEORGE GLOCKLER

**Spontaneous emission of protons during radioactive processes.** A. V. GROSSE. *Z. Physik* 54, 764-6(1929).—On the basis of Einstein's equation  $E = mc^2$  and Aston's curve of packing fractions (C. A. 21, 3543), G. shows that the emission of a proton from a radioactive element could only take place with the absorption of a great deal of energy and that therefore such a process would not take place of itself. G. G.

**The radioactivity hypothesis in the "Serono effect" of the irradiated phosphatides.** NICOLA GENTILE. *Rass. clin. terap. sci. affini* 27, 451-7(1928); cf. Serono and Cruto, C. A. 22, 4361.—Considering all the exptl. facts that have been gathered so far in the study of the "Serono effect," G. favors the hypothesis that this effect is an expression of a radioactivity produced in org. substances contg. elements of low at. wt. The photoactive rays emitted from the irradiated phosphatides are secondary, characteristic rays belonging to the same class as x- and  $\gamma$ -rays. The theory is supported by the following facts: the effect is distinctly related to the phenomenon of fluorescence. It may be produced by various electromagnetic wave lengths as are present in x-rays and the rays emitted from the sun or the Hg lamp. It manifests itself at a distance

from the irradiated substance. It persists for a long time after cessation of the primary irradiation. The theory of the Hertz-Hallwachs effect places the ultra-violet rays in the same class as x- and  $\gamma$ -rays concerning the ability of attacking the at. structure. Large wave lengths of the exciting rays are sufficient to induce photoactivity; the radiation emitted cannot be abundant in the org. substances composed of elements with a low enough at. wt. G. SCHWOCH

**The uranium-thorium ratio in monazites.** SATOYASU IMORI. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) 10, 229-36(1929).—U and Th were detd. in 5 monazites from different localities in Japan, Korea and Ceylon. Th was detd. chemically (Benz method) but as U is present in such small quantities in monazite it was calcd. from the Ra content (ratio of Ra to U =  $3.4 \times 10^{-7}$ ). Ra was detd. by boiling off the emanation from the samples dissolved in concd.  $H_2SO_4$ . A careful gravimetric estn. gave lower results than the calcd. No relation between the ratio of U to Th and the amt. of U or Th was found in the monazites. The estd. age of the monazites was calcd. from its He content (cf. *C. A.* 21, 1610). Thorouranium, parent of Th, with a half-value period of  $10^{-7}$  years must nearly have disappeared from the earth's crust. C. H. BADGER

**Deflection of molecular rays.** I. I. RABI. *Z. Physik* 54, 190-7(1929).—A beam of neutral atoms or mols. enters an elec. or magnetic field obliquely and particles having an elec. or magnetic moment suffer a deflection in the field much as light is refracted when entering an optically different medium. The method avoids the measurements of inhomogeneous fields. The magnetic moment of K is found to be one Bohr magneton. GEORGE GLOCKLER

**The polarization of canal rays. III. Canal rays for the mercury line 2537.** E. RUPP. *Ann. Physik* [5], 1, 289-300(1929); cf. *C. A.* 23, 2099. —The polarization relation  $J_p/J_s$  for the Hg line 2537 canal rays was measured. Polarization for this line occurs only if a disturbance of light emission occurs at the slit. Removal of this disturbance by baking out the slit causes polarization to disappear. The polarization relation depends on the nature of the gas and its pressure and on the magnetic field. The elec. vector for polarized canal rays is in the direction of the beam axis. On producing a diffuse beam polarization disappears. RAYMOND H. LAMBERT

**Polarization of neon lines due to an electron beam and due to neon canal rays.** W. HANLE AND B. QUARDER. *Z. Physik* 54, 819-25(1929). GEORGE GLOCKLER

**Polarization of the tungsten L radiations.** PAUL KIRKPATRICK AND IWAO MIYAKE. *Proc. Natl. Acad. Sci.* 15, 418-21(1929).—The states of polarization of the three lines  $L\alpha_1$ ,  $L\beta_1$  and  $L\gamma_1$  of W were examd. separately. The results are in accord with the consensus of earlier researches, no polarization being found for any line, though the method employed should have revealed any polarization as great as 1%. W. F. MEGGERS

**Polarization of fluorescence in mercury vapor.** W. HANLE AND E. F. RICHTER. *Z. Physik* 54, 811-18(1929). GEORGE GLOCKLER

**Decay of fluorescence in the case of molecules.** H. H. HUFFELD. *Z. Physik* 54, 484-97(1929).—The duration of luminosity in  $Na_2$ ,  $K_2$ ,  $I_2$  and Na resonance is of the order of  $10^{-8}$  sec. (cf. *C. A.* 21, 3023). GEORGE GLOCKLER

**Fluorescence in flames.** R. M. BADGER. *Z. Physik* 55, 56-64(1929).—Metal vapors show fluorescence in the flame. The alkali metals are an exception. Sensitized fluorescence could not be produced in a flame. Expts. on the extinction of Hg fluorescence in  $H_2-N_2$  mixts. at high pressure and low temp. showed that the action of mixts. can be calcd. roughly from the action of the individual gases. GEORGE GLOCKLER

**Preparation of luminescent substances.** N. F. ZHIROV. *Ukrainskii Khim. Zhur.* 3, Tech. Pt. 209-27(1928).—As carriers the very pure sulfides of Ca, Sr, Ba and Mg are used; they are prepd. by calcining the corresponding carbonates in a very high degree of purity with S. The following method of prepg.  $CaCO_3$  was found to be best for this purpose. Pure white marble is dissolved in tech. HCl; the marble taken in excess is allowed to settle during several days under its HCl soln., after which the latter is filtered, acidified by HCl, boiled, satd. with  $H_2S$ , boiled to remove  $H_2S$  and filtered hot. On cooling, 3%  $H_2O_2$  is added to the liquid in the quantity of about  $1/20$  of its vol., the mixt. is boiled till cessation of gas emission, filtered and pptd. by  $(NH_4)_2S$ . A weight of milk of lime equal to about  $1/10$  of that of the marble taken is added. After boiling several hrs. the lime becomes gray and the liquid is filtered. After cooling, a current of  $CO_2$  is passed into the liquid to complete resolu. of the ppt. at first formed, after which  $CO_2$  is completely removed by boiling and the ppt., which is formed again, is filtered. The color of the ppt. serves as indicator of purity: the grayer it is, the less pure the soln. If necessary, the purifying operation by means of  $Ca(OH)_2$  is re-

peated. The soln. obtained is evapd. to crystallize  $\text{CaCl}_2 \cdot 6\text{H}_2\text{O}$ , the crystals are redissolved in distd.  $\text{H}_2\text{O}$  and subjected to an electrolysis between 2 Pt plates with a current of 2 v. and 0.1 amp. not less than 24 hrs. The soln. is filtered, pptd. by a satd. soln. of  $(\text{NH}_4)_2\text{CO}_3$  and left standing together with the ppt. not less than 24 hrs. After that, the liquid is removed by decantation and the ppt. of  $\text{CaCO}_3$  is repeatedly washed, first with hot  $\text{H}_2\text{O}$ , then with cold  $\text{H}_2\text{O}$ , then with  $\text{EtOH}$  and  $\text{Et}_2\text{O}$ , air-dried and calcined slightly for  $1\frac{1}{2}$  hr. The reagents used in these operations must be very pure. The  $\text{H}_2\text{S}$  used should not be prepd. from pyrites; it is best to prep. it by the action of vaseline oil on S.  $\text{CO}_2$ , after being prepd. from marble and  $\text{HCl}$ , is washed by being passed successively through a soln. of  $\text{CuSO}_4$ , a soln. of  $\text{K}_2\text{MnO}_4$ , pure  $\text{H}_2\text{O}$  and is finally passed through cotton. Ashless filter paper should be used in all filtrations. Pure  $\text{SrCO}_3$  and  $\text{BaCO}_3$  are prepd. by the same lengthy process as pure  $\text{CaCO}_3$ . With  $\text{SrCO}_3$  one may start with either the com.  $\text{Sr}(\text{NO}_3)_2$  or  $\text{SrCl}_2$ , but in order to obtain  $\text{BaCO}_3$  it is necessary to start with  $\text{Ba}(\text{NO}_3)_2$ ;  $\text{BaCl}_2$  will not do. The corresponding sulfides are obtained by calcination with S; a certain quantity of sulfates is obtained thereby; the latter may be reduced either by pure starch, or by sugar. An admixt. of sulfates is not in itself harmful, since a 75% admixt. of this salt reduced the luminosity by only 8%. S used for this calcination must be extremely pure; it is best crystd. from aniline. As fluxes, salts contg. water of crystn. are used. The crucibles used are lined with lime and asbestos. The characteristics of luminophores are as follows. Bad luminophores are obtained by using  $\text{BaS}$  with  $\text{Rb}$  and  $\text{CaS}$ , or  $\text{SrS}$  with  $\text{Mn}$ . The best red luminophores are obtained by using  $\text{BaS}$  with  $\text{Cu}$  and  $\text{Rb}$ . The best yellow luminophores are obtained by using  $\text{SrBaS}$  with  $\text{Pb}$ ,  $\text{Cu}$ ,  $\text{Sb}$ ,  $\text{Tl}$ . In  $\text{CaS}$  gives a greenish light-blue luminophore,  $\text{In}$  in  $\text{SrS}$ —blue-green,  $\text{Th}$  in  $\text{CaS}$ —light bluish violet;  $\text{U}$  in  $\text{BaS}$  gives a bad luminophore. The best of the new activators are  $\text{In}$  in  $\text{SrS}$ ,  $\text{Zr}$  in  $\text{SrS}$ ,  $\text{V}$  in  $\text{CaS}$ . Of the complex luminophores the following are good:  $\text{SrS-Cu}$ ,  $\text{SrS-U}$ ,  $\text{Bi}$ ,  $\text{SrBaS-Th}$ ,  $\text{Pb}$ ,  $\text{Cu}$ ,  $\text{CuS-Tl}$ ,  $\text{U}$ ,  $\text{Bi}$  and  $\text{Rb}$ . B. N.

**Photoluminescence of liquids.** S. I. VAVILOV AND L. A. TUMMERMANN. *Z. Physik* 54, 270-6(1929).—Many liquids show a blue fluorescence when irradiated by the light of a Hg lamp. The spectra of this fluorescence are very similar for the different liquids. It appears that the phenomenon is caused by an impurity such as  $\text{O}_2$  or  $\text{CO}_2$  of the air, since so many different liquids as  $\text{H}_2\text{O}$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{C}_2\text{H}_5\text{O} \cdot \text{C}_2\text{H}_5$ ,  $\text{CH}_3\text{CO} \cdot \text{CH}_3$ ,  $\text{C}_6\text{H}_6$ ,  $\text{C}_6\text{H}_5\text{CH}_3$ ,  $\text{C}_2\text{H}_5\text{OH}$ , etc., show it. By repeated distn. of  $\text{H}_2\text{O}$  the fluorescence disappears.

GEORGE GLOCKLER

**Luminescence caused by x-rays in mercury vapor.** S. MROZOWSKI. *Z. Physik* 54, 422-6(1929); cf. *C. A.* 23, 39.—The visible and the ultra-violet light produced by x-rays in Hg vapor are due to the photoelectron produced by the x-rays. G. G.

**Theory of x-ray diffraction of liquids.** H. MARK. *Z. Physik* 54, 505-10(1929).—The intensity max. in the case of spherical mols. can be obtained theoretically by considering a liquid as a powder, the crystals of which have lattices of hexagonal or cubic closest packing with large temp. motion (cf. *C. A.* 23, 764). G. G.

**Diffraction of x-rays in liquids.** H. F. HERTLEIN. *Z. Physik* 54, 341-6(1929).—The diffraction of x-rays in liquids and liquid mixts. is thought to be an intermolecular rather than an intramolecular phenomenon (cf. *C. A.* 23, 764). GEORGE GLOCKLER

**X-ray diffraction haloes in the aqueous solutions of electrolytes.** HIKORCHI SHIBA AND TOKUNOSUKE WATANABE. *Sci. Papers Inst. Phys. Chem. Research (Tokyo)* 10, 187-92(1929).—By the measurement of photographs of x-ray diffraction haloes it is found that from aq. solns. of  $\text{H}_2\text{SO}_4$  the halo contracts continuously with increase in concn.; haloes from solns. of  $\text{KCl}$ ,  $\text{NaCl}$ ,  $\text{NH}_4\text{Cl}$  and  $\text{NH}_4\text{OH}$  in any concn. have the same size as that for  $\text{H}_2\text{O}$ ; haloes from solns. of  $\text{LiOH}$ ,  $\text{NaOH}$ ,  $\text{KOH}$  and  $\text{LiCl}$  expand as the concn. is increased; and haloes of  $\text{BeCl}_2$ ,  $\text{MgCl}_2$ ,  $\text{CaCl}_2$ ,  $\text{AlCl}_3$ ,  $\text{Al}(\text{NO}_3)_3$  and  $\text{Be}(\text{NO}_3)_2$  solns. show slight expansion and then a contraction with increase in concn. Halo contraction is assocd. with hydration of the cation. The diffraction at small angles is remarkable in dil. solns. as compared with pure  $\text{H}_2\text{O}$  and becomes weak in concd. solns. Tables of data and plates of patterns are included.

H. W. WALKER

**Homogeneity of x-rays by filtration.** N. MIROLUBOV AND I. POROKOV. *Z. Physik* 54, 399-407(1929).—The idea of homogeneity is defined as the no. of octaves within the ray. The relation between filter and voltage, given similar homogeneous rays, is deduced. GEORGE GLOCKLER

**Liberation of photoelectrons by x-rays at total reflection.** W. EHRENBERG AND F. JENTZSCH. *Z. Physik* 54, 227-35(1929).—The photoelec. current from a metal mirror reaches a max. near the angle of total reflection for x-rays and decreases rapidly to very small values for smaller values of the angle. GEORGE GLOCKLER

Photoelectric thresholds and photoelectric fatigue for iron, cobalt and nickel. GEORGE B. WELCH. *Phys. Rev.* 31, 709(1928); cf. *C. A.* 23, 763. E. J. C.

The surface photoelectric effect of the silver halide and silver sulfide. F. KRÜGER AND A. BALL. *Z. Physik* 55, 28-43(1929).—The surface photoelec. effect is studied on AgCl, AgBr, AgI and Ag<sub>2</sub>S as a function of wave length and compared with the volume photoelec. effect and the photochem. effects. GEORGE GLOCKLER

Inversion of the photovoltaic effect by hydroxyl and hydrogen ions. G. ATHANASIU. *Compt. rend.* 188, 786-8(1929).—The sign and magnitude of the photovoltaic effect for Ag-AgI, Hg-Hg<sub>2</sub>I<sub>2</sub>, and Ag-Ag<sub>2</sub>S cells can be changed by modifying the OH<sup>-</sup> and H<sup>+</sup> concns. of the electrolytic media. Thus for the cell Ag-AgI | KCl neutral | Ag-AgI the electrode becomes pos. on illumination but by making the electrolyte basic a neg. charge is obtained. The addn. of OH<sup>-</sup> also is found to shift the sensitivity max. from  $\lambda$ 4240 to  $\lambda$ 4300 Å. U. Similar inversion effects are noted for Hg-Hg<sub>2</sub>I<sub>2</sub>, Cu-Cu<sub>2</sub>I<sub>2</sub>, and Cu-Cu<sub>2</sub>I<sub>2</sub> cells. The addn. of OH<sup>-</sup> to the Ag-Ag<sub>2</sub>S cell, on the contrary, augments the neg. photovoltaic e. m. f. With some electrodes regions of sensitivity are found common to the 2 effects. This effect, usually observed, of an increased e. m. f. due to addn. of H<sup>+</sup> and OH<sup>-</sup> ions to the electrolyte is attributed to the acceptance by the electrolyte of one of the products of photochem. decompn. H. R. MOORE

Multiple absorption and secondary K-absorption limits. B. B. RAY. *Z. Physik* 55, 119-26(1929).—It is assumed that a single x-ray quantum can be absorbed by more than one electron in various energy levels. The calcd. absorption limits are very near to the exptl. observed ones (cf. *C. A.* 22, 2322). GEORGE GLOCKLER

Absorption of electrons. W. BOTHE. *Z. Physik* 54, 161-78(1929).—The absorption of  $\beta$ -rays is studied theoretically by assuming that the reduction in nos. in the absorbed beam is due to many small-angle scatterings. The distribution in direction in normal incidence is in agreement with expt. The calcd. absorption coeff. for Al for varying velocity agrees with the exptl. value. The change of mass absorption coeff. with the material used is not given correctly because of simplifying assumptions made in the theory. GEORGE GLOCKLER

Gas adsorption determined by experiments on electron diffraction. L. H. GERMER. *Z. Physik* 54, 408-21(1929).—With the proper exptl. conditions it is possible to obtain 4 different diffraction patterns when electrons are reflected from a single crystal of Ni. The 4 patterns are due to: the space lattice of the crystal; the first outermost layer of Ni atoms; a monatomic adsorbed gas layer and an outer deeper layer of adsorbed gas (cf. *C. A.* 22, 4354). GEORGE GLOCKLER

Selective absorption by excited mercury vapor. E. P. METCALFE AND B. VENKATESACHAR. *Nature* 123, 761(1929). GREGG M. EVANS

Efficiency of resonance of  $\lambda$ 2537 of mercury. W. HANLE. *Z. Physik* 54, 848-51(1929).—The efficiency of resonance for electrons of 4.9-10.0 v. speeds is measured. The efficiency curve shows a max. at  $1\frac{1}{2}$  v. above the resonance point. G. G.

Critical potentials in mercury. V. PAVLOV AND N. SUEVA. *Z. Physik* 54, 236-45(1929).—Several crit. potentials are found for Hg below 4.9 v. which do not fit into the optical energy diagram. GEORGE GLOCKLER

Increase of the sparking potential of a gas mixture by irradiation. F. M. PENNING. *Proc. Acad. Sci. Amsterdam* 32, 341-3(1929); cf. *C. A.* 22, 1904, 3352.—A review of the expts. done earlier, with further explanation of the theory. E. SCHOTTE

Second-order Stark effect in the Balmer series of hydrogen. H. RAUSCH VON TRAUBENBERG AND R. GEBAUER. *Z. Physik* 54, 307-20(1929).—The middle component agrees with Schroedinger's theory; the higher components do not. G. G.

A note on the hydrogen chromosphere. W. H. MCCREA. *Proc. Cambridge Phil. Soc.* 24, 506-15(1928).—A mathematical treatment of the equil. between H and its ions in the chromosphere. J. B. AUSTIN

Calculation of the energy of helium. EGIL A. HYLLERAAS. *Z. Physik* 54, 347-66(1929).—The energy of par-He is calcd. by methods of approximation from the wave-equation expressed in distances only. The calcd. value is  $E = -1.45162 R_{\text{He}}/h$  to be compared with the exptl. value  $E = -1.45182 R_{\text{He}}/h$ .  $R_{\text{He}}$  = Rydberg const. for He,  $h$  = Plank's const. With ortho-He the approximations are not carried out so completely but agreement between calcd. and exptl. values is deduced (cf. *C. A.* 22, 2873). GEORGE GLOCKLER

Frequencies of the carbonate group. C. SCHAEFER. *Z. Physik* 54, 676-8(1929).—This is a criticism of remarks by K. F. Herzfeld in Handbuch d. expt. Physik VII, 273, regarding interpretation of the infra-red frequencies of the CO<sub>3</sub> group. G. G.

Electrodeless discharge with undamped excitation. H. STEINHÄUSSER. *Z.*

*Physik* **54**, 788-97(1929).—Striking potentials and conductivity as dependent on gas pressure in air, O<sub>2</sub>, N<sub>2</sub>, CO<sub>2</sub>, H<sub>2</sub>, He, Ne and A are studied. GEORGE GLOCKLER

**Transparency in the infra-red of thin metal foils and their electrical conductivity.** H. MURMANN. *Z. Physik* **54**, 741-60(1929).—It is shown experimentally that the transparency of Ag, Bi and Sb foils in the range  $\lambda = 25\mu$  to  $\lambda = 110\mu$  is independent of the wave length, and depends only on the product of thickness and elec. cond., in agreement with theory. GEORGE GLOCKLER

**Chemical and optical properties of reactive organic groups.** A. DADIEU. *Z. Elektrochem.* **35**, 283-91(1929).—A substituent may change the location of the max. and width and intensity of absorption bands, or it may alter the type of absorption spectrum. The latter type is not considered. Displacement of the max. is compared in  $\mu\mu$ , width at half the max. in  $\mu\mu$  and change of intensity by the difference in molar extinction. Data on perylene (cf. *C. A.* **23**, 1351), PhH and C<sub>10</sub>H<sub>8</sub> indicate that the displacement of the max. depends on the kind of nucleus and position of substitution. Broadening of the band does not parallel displacement. A similarity is found between decrease of intensity and broadening of the band but they are apparently not entirely due to the same factor. The more strongly neg. a group the more it displaces the absorption band, with NH<sub>2</sub> an exception because of NH<sub>2</sub> type complex formation. The parallelism between negativity and bathochromic properties is important in prediction of the optical effect of a substituent. Apparently in the cases considered an electron is raised to a higher energy level but this effect is not sufficient to change the type of energy distribution, the max. only being shifted. Broadening of the band depends on changes in the outer electron structure due to the substituent. The degree of steric hindrance, a non-rigid atom being assumed, is a factor in the neg. nature of a group. Other methods of measurement of reactivity are reviewed. FOSTER DEE SNELL

**Evolution of the new quantum mechanics.** N. M. BLYTH. *Science Progress* **23**, 619-32(1929).—A review. JOSEPH S. HEPBURN

**New quantum theory.** RASCHKO ZAYCOFF. *Z. Physik* **54**, 588-9(1929).—Mathematical. GEORGE GLOCKLER

**Quantum theory of radioactivity.** J. KUDAR. *Z. Physik* **54**, 297-9(1929); cf. *C. A.* **23**, 2352.—Mathematical. GEORGE GLOCKLER

**Quantum theory of the nucleus.** TH. SEXL. *Z. Physik* **54**, 445-8(1929).—Mathematical treatment of the appropriate wave equation of radioactive decay as given previously by Gurney and Condon (cf. *C. A.* **23**, 329) and Gamow (*C. A.* **23**, 2352). GEORGE GLOCKLER

**Wave theory of the electron.** J. M. WHITTAKER. *Proc. Cambridge Phil. Soc.* **24**, 501-5(1928).—In Darwin's method of accounting for the "duplexity" of the atom without using the spinning-electron hypothesis, the work can be given invariance of form only by replacing the 4 wave functions by 16. This complication is avoided by specifying the electron wave as a 6-vector analogous to the electromagnetic force vector, the first 3 components being the components of a space vector analogous to the elec. force, and the last 3 the components of a space vector analogous to the magnetic force. The differential equations satisfied by these functions are obtained by assuming that in a null magnetic field they admit a soln. representing a plane wave advancing with uniform velocity. The theory leads to the correct energy levels for the fine structure of the H atom, and gives correct results for the free motion of the electron. B. C. A.

**Wave-mechanical treatment of the temperature coefficient of electrical resistance.** G. BORELIUS. *Z. Physik* **54**, 806-10(1929).—The theoretical formulas derived so far fail to give agreement with expt. (cf. *C. A.* **22**, 4347). GEORGE GLOCKLER

**Diffraction of short electromagnetic waves by a crystal.** W. L. BRAGG. *Scientia* **45**, 153-62(1929).—A popular account of the fundamentals of diffraction of x-rays by crystals. G. L. CLARK

**Spectral-analytical method for the determination of low melting and volatile substances by the use of the cathode-ray tube.** O. EISENHUT AND E. KAUPP. *Z. Physik* **54**, 427-32(1929).—The x-ray emission spectrum of a substance is obtained by placing the material near the window of a cathode-ray tube. The emerging electrons excite the characteristic x-rays of the material, and these rays are analyzed in the usual way. GEORGE GLOCKLER

**A spectroscopic method for the detection of unstable intermediate products in active gases and its application to active oxygen, nitrogen and hydrogen.** Z. BAY AND W. STERNER. *Z. physik. Chem.*, Abt. B, **3**, 149-61(1929).—By means of a weak, const. vibratory discharge there is produced within the discharge generated in active

gases an emission spectrum, the examn. of which leads to the identification of intermediate products. With quant. expts. it is possible to follow spatially and temporally the alteration velocity of intermediate products in the reacting gas. The efficiency of the method is demonstrated by active H, N and O. In active N the arc line of N was detected for the first time, which makes it very reasonable that N atoms play an essential role. H. W. WALKER

**Recent advances in science: Physics.** L. F. BATES. *Science Progress* 23, 577-84 (1929).—A review of recent work on cosmic rays, and the Raman effect. J. S. H

**The Raman effect.** A. PETRIKALN and J. HOCHBERG. *Z. physik. Chem.*, Abt. B, 3, 217-28 (1929).—The Raman spectra of the following compds. have been observed: bromobenzene, pyridine, naphthalene, (both in liquid condition and in benzene soln.) nitromethane, acetonitrile, hexane, cyclohexane, diphenylmethane (in alc. soln.), triphenyl methane (ether soln.), carbon disulfide, sodium azide (in aq. soln.). Diphenylmethane and triphenyl/methane gave continuous spectra showing no lines; Na azide gave one line on a continuous background; the rest showed a no. of Raman lines. The spectra of pyridine and bromobenzene are quite similar and show a marked resemblance to the Raman spectra of benzene and chlorobenzene reported in the literature; the naphthalene spectrum is entirely different. Hexane and cyclohexane give almost identical spectra. J. B. AUSTIN

**The Raman effect in gases.** E. L. HILL and F. C. KEMBLE. *Proc. Nat. Acad. Sci.* 15, 387-92 (1929).—Recent results on the Raman effect in HCl and H<sub>2</sub> can be interpreted by assuming a new selection rule for the rotational quantum no.,  $j$ . In the ordinary infra-red vibration-rotation spectrum, where the  $Q$  branch is absent, the selection rule is  $\Delta j = \pm 1$ . However, in order to account for the appearance of Raman lines corresponding to the "missing line" in the vibration-rotation band and to account for the absence of alternate lines in the pure rotation spectrum, the rule must be changed here to  $\Delta j = 0, \pm 2$ . It is shown that this rule under suitable restrictions can be derived from the new quantum mechanics. W. F. MEGGERS

**A study of the Raman effect in acetone.** JOHN W. WILLIAMS and ALEXANDER HOLLAENDER. *Proc. Nat. Acad. Sci.* 15, 421-3 (1929).—Acetone was irradiated with Hg light and the scattered light was photographed with glass prism and with quartz spectrographs. The time of exposure was 10 to 14 hrs. for the glass instrument and 30 to 50 hrs. for the quartz. Thirteen lines were recorded; their wave lengths range from 4090 to 4729 Å. U. Twelve of these lines correspond, within the limits of exptl. error, to absorption bands which have been observed in investigations of infra-red spectra. The remaining calcd. absorption line, 18.77 $\mu$ , is beyond the region ordinarily studied in infra-red work. W. F. MEGGERS

**About the production of the continuous x-ray spectrum.** A. SOMMERFELD. *Proc. Nat. Acad. Sci.* 15, 393-400 (1929).—The continuous spectrum of x-rays produced in a thin target is treated from the standpoint of wave mechanics. W. F. M

**M-x-ray absorption spectra; tungsten to uranium.** ERNST LINDBERG. *Z. Physik* 54, 632-42 (1929).—The absorption edges  $M_V$ ,  $M_{IV}$  and  $M_{III}$  are detd. for the elements: W, Pt, Au, Hg, Tl, Pb, Bi, Th and U (cf. *C. A.* 23, 32). G. G

**Perturbations in band spectra.** I. JENNY F. ROSENTHAL and F. A. JENKINS. *Proc. Nat. Acad. Sci.* 15, 381-7 (1929).—The series of lines which make up a band in the spectrum of a diatomic mol. show, in certain cases, irregularities which are known as perturbations. When these occur, some of the energy terms involved must deviate from a regular term-formula of the ordinary type. Until recently no theoretical interpretation of these phenomena had been attempted, and the empirical data were few and scattered. However, accurate descriptions are now available of the quant. relations in perturbations in several spectra (CN, SiN, CO, N<sub>2</sub><sup>+</sup>, BeO, HgH<sup>+</sup>). The obvious method of studying such cases is to derive a formula to fit the frequencies of the regular lines of the series, and then to plot the deviations of all observed lines from this formula. Such curves are found to have a form similar to a curve of anomalous dispersion in the region of the resonance frequency. Kronig has recently (*C. A.* 23, 32) discussed the origin of perturbations from the standpoint of the wave mechanics. The theory is supported by verification of several predictions but there appear also to be exceptions. W. F. MEGGERS

**New relations in the band spectrum of helium.** G. H. DIEKE, S. IMANISHI and T. TAKAMINE. *Z. Physik* 54, 826-43 (1929). GEORGE GLOCKLER

**Analysis of band spectrum of helium.** W. WEIZEL. *Z. Physik* 54, 321-40 (1929).—Former designation of electron terms in the He<sub>2</sub> band spectrum is supported by wave-mechanical analysis. A powerful source of the He<sub>2</sub> band spectrum is described. The

upper limit for the heat of dissocn. of  $\text{He}_2$  is 55,000 cal./mol. Several new bands are given (cf. *C. A.* 23, 769).

**Intensity measurements in the band spectrum of mercury hydride.** W. KAPUŚCINSKI AND J. G. EYMERS. *Z. Physik* 54, 246–56(1929).

**The band systems in the molecular spectrum of hydrogen. I. The singlet system.** W. FINKELNBURG AND R. MECKE. *Z. Physik* 54, 193–214(1929).—383 lines of the Balmer band system are assigned (cf. *C. A.* 23, 564). **II. The triplet system.** *Ibid* 597–631.—Band spectra are analyzed, and bands of molecular  $\text{H}_2$  are systematically arranged.

**The continuous spectrum of the hydrogen atom.** PAUL S. EPSTEIN AND MORRIS MUSKAT. *Proc. Natl. Acad. Sci.* 15, 405–11(1929).—The purpose of this paper is to obtain expressions for the intensities in the continuous spectrum of H suitable for numerical calcs. This purpose is accomplished by means of a new integral representation for the wave function in this special case. As examples of application the absorption spectra of H beyond the limits of the Balmer and of the Lyman series as well as certain limiting values of the absorption are calcd.

**Series in the arc spectrum of krypton.** W. GREMMER. *Z. Physik* 54, 215–26(1929); cf. *C. A.* 23, 33.—The arc spectrum of Kr is similar to the spectra of Ne and A.

**Mercury-argon and mercury-krypton bands.** O. OLDENBERG. *Z. Physik* 55, 1–15(1929); cf. *C. A.* 23, 1729. —Bands observed in Hg-A and Hg-Kr mixts. are studied and analyzed.

**The fluorescence spectrum of oxygen.** F. RASETTI. *Proc. Natl. Acad. Sci.* 15, 411–14(1929).—The spectrum of the light from a Hg arc scattered by  $\text{O}_2$  at atm. pressure and photographed with a quartz spectrograph, shows, besides Raman lines, a series of doublets extending from the ultra-violet limit of the spectrum on the plate down to the visible region. This appears as a fluorescence spectrum excited by the resonance line 1849 Å. U. of Hg which is strongly absorbed in  $\text{O}_2$ . These fluorescent doublets have a sepn. of about 60  $\text{cm}^{-1}$ , their relationship with the known  $\text{O}_2$  bands is discussed.

**The structure of the fundamental line and several other lines of the cadmium spectrum.** ANNELEISE SCHRAMMEN. *Ann. Physik* 87, 638–52(1928).—The work previously reported (cf. *C. A.* 22, 22) is continued with a new quartz Lummer-Gehrcke plate of superior quality. The structure of the resonance line  $1S_0 - 2^1P_1$  (2288.74 Å. U.) appeared in the earlier investigation to be dependent on discharge conditions in the Cd lamp. This line was also studied by Wood, who found 2 components with the same intensity with sepn. of 0.021 Å. U. These results are now explained by self-reversal. The line is studied again both in emission and absorption and it appears that this line has an unresolved satellite with a difference  $d\lambda - 0.00035$  Å. U. or  $d\nu + 0.067$   $\text{cm}^{-1}$  from the principal component. The structures of several lines (2660.45, 3081.03, 3261.17, 2403.74 and 3500.09 Å. U.), which could not be detd. before without ambiguity, are remeasured.

**The spectra of Zn II, Cd II, In III and Sn IV.** R. J. LANG. *Proc. Natl. Acad. Sci.* 15, 414–8(1929).—In the Zn II spectrum 6 new combinations between known terms are located. In Cd II the 7 S term is found and 2 intercombinations are recorded. In In III one new multiplet, based on known term values, is given and possible values for the 6 F terms are obtained. In Sn IV 4 multiplets are located, all based upon previously known term values. The new lines lie in the very short wave-length region of the spectrum investigated by means of a vacuum spectrograph and a vacuum spark between metallic electrodes.

**Infra-red spectrum of halogen compounds.** G. B. BONINO. *Z. Physik* 54, 803–5(1929).—The lack of agreement between the Raman lines and the infra-red lines in the case of  $\text{C}_2\text{H}_2\text{Cl}_4$  and  $\text{C}_2\text{H}_2\text{Cl}_2$  as found by Pringsheim and Rosen (*C. A.* 23, 39) does not exist.

**The ultra-violet bands of alkaline earth sulfide phosphors.** OTMAR SCHILLENBERG. *Ann. Physik* 87, 677–715(1928).—The conditions for prep. alk. earth sulfide phosphors with ultra-violet bands are studied. The metals were Fe, Cu, Zn, Ag, Sb, Pb and Bi in  $\text{CaS}$ , Fe, Zn, Ag, Pb and Bi in  $\text{SrS}$ , Cu, Pb and Bi in  $\text{BaS}$ ; it was found that for good ultra-violet emission only minute quantities of metal could be used. Analogous to the displacement of visible phosphorescence bands toward longer waves with transition from Ca to Sr to Ba, the same behavior is found for ultra-violet bands. The temp. properties of the new bands are detd. and described in detail.

**The spectrum emitted by a carbon plate under bombardment.** A. A. NEWBOLD. *Phil. Mag.* [7], 7, 706–19(1929).—A special quartz tube was constructed and an electro-

static method developed for the investigation of soft x-ray spectra. The method was applied to the spectrum emitted by a carbon plate under electron bombardment up to 600 volts. Over the frequency range 5700 to 26,000 the spectrum found was either identical with, or at least resembled very closely that mapped by Millikan and Bowen for gaseous carbon.

COLIN G. FINK

Present trend in the construction and application of the electric furnace in the foundry. ALBERT LEVASSEUR. *J. four élec.* 38, 185-7(1929). C. G. F.

Continuous electric furnace manufacture of cyanamide. GEORGE BASSEREAU. *J. four élec.* 38, 153-6(1929).—A detailed review of the manuf. of granulated cyanamide and its advantages over other varieties of cyanamide. The equipment used in the manuf. of the granulated product consists of a continuous elec.-resistance tunnel furnace 40 m. long and 1.70 m. wide, which is divided into 3 zones. The  $CaC_2$  is rapidly taken to  $900^\circ$  in the first zone; reaction is completed in the second zone where temp. is  $1100^\circ$  due to exothermic nitration reaction; in the third zone suitable ventilation cools the cyanamide. The yield is greater than 86%. The product is granulated by subjecting the crude product to hydration, adding sufficient  $H_2O$  to change free lime and to destroy residual carbide; after thorough mixing the material is transferred to a series of pans and held in layers for 2 hrs. to permit completion of reaction. It is then stirred well, cooled and taken to app. for granulation. More  $H_2O$  is added and the granulation is carried out in a specially designed grinder. The equipment used is illustrated.

M. McMAHON

Electric (heated) galvanizing (tanks). ROBERT A. CLARK, JR. *Elec. World* 93, 1321-3(1929).—The introduction of elec. heating resulted in close temp. control and

consequent improved quality of product. The heat distribution of the bath is more uniform than with other heating methods.

**Electrical cleaning of blast-furnace gas.** ROBERT DURRER. *Blast Furnace & Steel Plant* 17, 862-3 (1929).—Elec. pptn. is discussed. C. G. F. E. J. C.

**Electrolytic crystal growth of copper in copper sulfate solutions.** IRMGARD CHIOU. *Dissertation, Greifswald* 1927, 45 pp.; *J. Inst. Metals* 39, 595.—Expts. have been made on the growth of electrolytic Cu deposits from sulfate electrolytes, with varying conditions of c. d., temp., acidity and concn. of electrolyte. In the first series a single crystal Cu sphere 0.6-0.8 cm. in diam. was used as cathode inside a cylindrical Cu anode 5 cm. in diam. In  $N$  CuSO<sub>4</sub> soln. at 20° the cathode grew as a single crystal with c. ds. between 0.5 and 1.7 amp. per sq./dm.; above and below these limits the deposits were polycryst. Addn. of 6.9 gm./l. of concd. H<sub>2</sub>SO<sub>4</sub> altered the above interval to 0.06-0.4 amp. per sq./dm.; in both cases, however, the final single crystal obtained tended to approx. an octahedron in shape. By raising the temp. of the neutral soln. or by increasing the concn. of Cu salt, the single-crystal deposition tends to take place at higher c. ds. In the second series of tests an annealed Ag sheet was used as cathode; with c. ds. within the above-mentioned limits and under the same conditions of temp., acidity and concn., the crystal structure of the deposited Cu represents an isomorphous growth on the Ag crystals of the cathode. A third series, using a hard-rolled Ag sheet anode, produced a fibrous Cu deposit under the above conditions. In both the latter cases c. ds. outside the stated limits produced an irregularly oriented deposit. H. L. D.

**Some recent work on silver plating.** F. B. SANIGAR. *Electroplaters' and Depositors' Tech. Soc.*, Advance copy, 1928, 61-4; *J. Inst. Metals* 39, 597-8.—The effect of the carbonate and free-cyanide content in the Ag-plating soln. upon the hardness of the deposit is described. A suitable method to det. the hardness was found to be the measurement of the breadth of a scratch produced on the deposit by a diamond under a load of 200 g.; the thickness of the deposit was in each case 0.00063 in. The effect of increasing Na<sub>2</sub>CO<sub>3</sub> content was a regular decrease in the hardness of the deposit. Softer deposits also resulted on adding free cyanide up to about 180%, the effect being less marked at the higher figures. A peculiar bright deposit gradually developed as the free cyanide was progressively increased to 600%, this being harder than the softest deposit obtained. Fifty to 100% free cyanide is considered the most satisfactory range. H. L. D.

**Silver plating.** A. E. NICOL. *Electroplaters' and Depositors' Tech. Soc.*, Advance copy, 1928, 49-60; *J. Inst. Metals* 39, 597.—The factors encountered in the com. electrodeposition of Ag are examd. The present-day silver-plating process is claimed to be efficient and satisfactory. Good deposits are obtainable from solns. varying very widely in compn. For light deposits, a content of 2 oz./gal. of Ag and for heavy deposits 3.25-4 oz./gal. is recommended. The permissible free cyanide content varies with the age of the soln. The presence of carbonates increases the cond. and the "throwing power" of the soln. and is not deleterious, producing a finer crystal structure. Chlorides are deleterious. Comparatively small increases in temp. are accompanied by undesirable results, while 3 amp. per sq. ft. is considered a satisfactory c. d. Methods of analysis of the Ag, carbonate and cyanide content are given. H. L. D.

**A comparison between sodium cyanide and potassium cyanide silver-plating solutions.** EDWARD B. SANIGAR. *Metal Ind.* (London) 34, 539-40 (1929); cf. *C. A.* 23, 43.—Twenty-four spoons were exactly similarly prepd. for plating and placed in vats with regular batches of work. The plated spoons were examd. by experts who found it impossible to distinguish between the ones plated in NaCN and those plated in KCN baths. On the basis of finishing losses, the spoons plated in NaCN solns. were slightly superior (4.5%) to those from KCN solns., which, at least, shows that NaCN is equal to KCN for the purpose. W. H. BOYNTON

**Bent cathode test for determining the optimum ratio of chromic acid to sulfate in chromium-plating baths.** WALTER L. PINNER AND EDWIN M. BAKER. *Metal Ind.* (London) 34, No. 24, 585-6, 611-2 (1929).—See *C. A.* 23, 2664. E. C. M.

**Eliminating health hazards in chromium plating.** J. J. BLOOMFIELD AND WILLIAM BLUM. *Chem. Met. Eng.* 36, 351 (1929); cf. *C. A.* 22, 4385. E. J. C.

**Plating and polishing.** W. JAMES. *Electroplaters' and Depositors' Tech. Soc.*, Advance copy, 1928, 41-8; *J. Inst. Metals* 39, 599.—Practical hints and observations are given on the processes of electroplating and polishing. The method of obtaining the fine old "church" finish is described, and notes on lacquering, dips for non-ferrous metals and nickel-plating solns. are given. The composite deposit, Ni-Cu (from sulfate

soln.)-Ni is recommended. Some observations on the position of Cr plating are included. H. L. D.

A new method of studying the electrochemical behavior of substances in very dilute solution. F. JOLIOR. *Compt. rend.* 188, 1106-8(1929).—J. has previously (*C. A.* 21, 3152) described a method of measuring very small electrolytic deposits of radioactive substances by measuring their radioactivity. The new method can be used for any substance. The electrode consists of a sheet of glass bearing a transparent layer of Au or Pt deposited by cathodic projection. The light transmitted by the electrode is measured by a photo-elec. cell. As the substance is deposited the light transmitted becomes less. From this the rate of deposit can be calcd. Using this electrode for the deposition of Bi from dil. solns. of the nitrate, about 0.05 v., referred to the calomel electrode, was obtained for the normal potential. Again with a  $10^{-4}$  N soln. of tellurous acid in a 0.2 N  $\text{HNO}_3$  soln. J. obtained a potential of -0.11 v. with respect to the calomel electrode. On adding a satd. soln. of  $\text{SO}_2$  to the electrolyte, the rate of deposit slowed down to zero. This corresponds to the pptn. of Te from more concd. tellurous acid solns. by  $\text{SO}_2$ . A. C. HIGGINS

Reversible electromotive force of electrolysis. J. VUILLERMOZ. *Compt. rend.* 188, 1098-9(1929).—The difference in potential between a negatively polarized Pt electrode and 2N  $\text{H}_2\text{SO}_4$  was observed at the instant the current was shut off and for the first half sec. thereafter. Simple breaking of the circuit did not cause an instantaneous variation in potential. When the break was accompanied by a static discharge across the electrode-electrolyte surface there was an instantaneous variation. The reversible e. m. f. was -0.49 v. The results are explained by considering the electrode-electrolyte contact as a parallel circuit composed of a resistance and a condenser of which the capacity  $c = q_1/u_1 = q_2/u_2 = \dots$ , where  $q_n$  is the electrostatic discharge and  $u_n$  is the instantaneous variation.  $c$  was 10 to 40 microfarads per sq. cm. A. C. HIGGINS

Electrolytic formation of sodium arsenate. O. A. ESIN. *Z. Elektrochem.* 35, 234-40(1929).—A soln. of 80.5 g.  $\text{As}_2\text{O}_3$  and 100.6 g. NaOH in 1 l.  $\text{H}_2\text{O}$  was electrolyzed with Fe electrodes, without diaphragm and with a c. d.  $D_K = D_A = 0.03$  amp./cm<sup>2</sup>. Considerable reduction of the electrolyte on the cathode takes place. The method is improved by the use of a diaphragm and weaker solns. (70 g.  $\text{As}_2\text{O}_3$  and 87.5 g. NaOH per l.). Different  $D_A$  values result in different grades of oxidation. A. E. BEITLICH

Electrolytic reduction of benzoic acid. F. SOMLÓ. *Z. Elektrochem.* 35, 261-5 (1929).—Phthalic acid was electrolyzed and a product found which was similar in chem. behavior to an oil which Baur and Mueller (*C. A.* 22, 1894) had found by the electrolysis of benzoic acid, and which they regarded as cyclohexenone. The substance is in both cases an Et ester of  $\Delta$ -1,3-dihydrobenzoic acid. The presence of  $\text{CO}_2$  and CO in the cathode gas is due to electrolysis of the solvent and not to the benzoic acid. A. E. BEITLICH

The electrolyses of isomeric caproic acids. SHERLOCK SWANN, JR. *Trans. Am. Electrochem. Soc.* 56, preprint, 9 pp.(1929).—The electrolyses of diethylacetic acid and methylpropylacetic acid have been carried out. The Kolbe synthesis of hydrocarbons does not take place with either of the acids studied. The investigation is being continued. C. G. F.

Electrosynthesis of hydrocarbons. LUIS MERMEJO AND LUIS BLAS. *Anales soc. españ. fis. quim.* 27, 228-35(1929).—In prepn. of  $\text{C}_2\text{H}_6$  by electrosynthesis a quant. yield is obtained by using a satd. soln. of ZnAc at a temp. below 20° and current density of 100 amp. per sq. dm. In electrolysis of  $(\text{AcO})_2\text{Pb}$  it was found that an anhyd. electrolyte is required to obtain Pb tetraacetate; that aq. acid and neutral acetate solns. subjected to electrolysis always produce  $\text{PbO}_2$  on the anode by decompn. of the tetraacetate formed; that in alk. solns. of basic acetates no tetraacetate is formed, but only a simple oxidation of basic acetate forms  $\text{Pb}_2\text{O}_3$ ; that  $\text{C}_2\text{H}_6$  is produced in all these electrosyntheses. E. M. SYMMES

A photoelectric smoke recorder. E. H. VEDDER. *Elec. J.* 26, 199-201(1929).—A beam of light is projected through a stack into a lens which concentrates the light on a photoelec. cell. The amplified response then actuates a recording instrument. A double-box construction makes the units weatherproof. Air is drawn in at the vent at the rear of the unit and around the internal box, which is kept covered, and into the holes in the pipe connecting the internal and external boxes. This air flows through the pipe on which the units are mounted on the front of the internal box. Photographs are shown of the amplifier and control unit, and of the light source unit, and graphs show the schematic arrangement of the smoke detector, characteristics of the

photo-cell and of the amplifier tube, the wiring of the smoke recorder, sections of a smoke recorder chart, and the graphic instrument which keeps a continuous record of smoke d.

**The incandescent electric lamp.** KENNETH R. SWAN. *Electrician* 102, 724 (1929).—Historical sketch emphasizing the world's indebtedness to Sir Joseph Swan.

C. G. F.

**Electric dust precipitation.** F. MUELLER AND A. SCHODER. *Commonwealth Eng.* 16, 162-8(1929).—A review.

C. G. F.

**Properties and tests of carbon brushes for motors and generators.** G. M. LITTLE. *Elec. J.* 26, 194-8(1929).—Some results are given of an extensive research in connection with C brush testing in an attempt to correlate some of the properties of the brushes with their performance in different kinds of field service, and to improve the quality of the brushes. All prominent makes of brushes and about 400 exptl. samples were examd., in part at least, according to a definite schedule. Tests indicating the phys. properties of the brushes include: the heat flow, which is a quick detn. of thermal cond., an air flow porosity test, magnetic susceptibility, sp. resistance, strength, tone test and porosity. Tests indicating the chem. properties are: % ash and volatile matter. Operating characteristics include: contact drop, coeff. of friction, and life and commutation. Special machines have been developed such as: (1) an app. for investigating the action of the circulating current that flows from bar to brush to bar under the brush face, (2) a machine for studying the behavior of different grades of C brushes when subjected to extremely short arcs, (3) a special traction-brush testing machine showing differences in commutation and life, (4) a machine detg. the tendency of a brush to chip, (5) a machine for measuring the ability of a brush to resist side wear, and (6) a slip-ring test device.

W. H. BOYNTON

**A sensitive roughneck (direct current regulator).** W. SCHARLCHLIN. *Elec. J.* 26, 216-24(1929); 22 illus.—A rugged electro-dynamic regulating device for controlling voltage, current, load, speed or torque of d. c. machines.

**Electric battery.** FERNAND C. F. PORTAIL (to Soc. anon. le Carbone). U. S. 1,716,461, June 11. See Brit. 291,420 (C. A. 23, 1063).

**Elastic sealing composition for dry-cell batteries.** ARLIE W. SCHORGER (to Burgess Battery Co.). U. S. 1,717,172, June 11. A sealing compn. is formed from asphalt (m. 117°) 80-82.5, Montan wax 10-15.5 and linseed oil 2-10 parts.

**Gas accumulator battery.** RENE OPPENHEIM. U. S. 1,717,244, June 11. An intimate mixt. of a finely divided porous conducting material such as charcoal, a pectizable colloidal soln. such as a starch compn. and a concd. soln. of an electrolyte such as  $\text{NH}_4\text{Cl}$  are used together; the colloidal soln. serves both to render the porous conducting material impermeable to liquids without destroying its permeability to gases and to immobilize the electrolyte. Current-conducting material such as retort-carbon rods penetrates the center of the mixt.

**Storage battery.** EDWARD A. LUNDGREN (to Revere Rubber Co.). U. S. 1,715,935, June 4. Structural features.

**Storage battery.** JOE B. PARSONS (to Prest-O-Lite Storage Battery Corp.). U. S. 1,716,598, June 11. Structural features.

**Storage battery.** STANLEY SWENSON. U. S. 1,716,197, June 4. Structural features.

**Storage battery.** HARLAND D. WILSON and ALBERT L. HOPKINS (to Prest-O-Lite Storage Battery Corp.). U. S. 1,716,610, June 11. Structural features.

**Storage battery.** RENÉ É. BRENNER. Fr. 652,758, Sept. 22, 1927. Construction of plates is given.

**Storage batteries.** LOUIS F. J. ROUSSEAU. Fr. 652,716, Sept. 15, 1927. The plates are sepd. by insulating frames forming tight compartments filled with electrolyte.

**Storage batteries.** I. G. FARBERIND. A.-G. Fr. 654,998, May 30, 1928. Method of making Pb electrodes is given.

**Storage battery plates.** LAWRENCE J. PEARSON (to Philadelphia Storage Battery Co.). U. S. 1,716,320, June 4. A regulated volume of air is circulated over negative storage battery plates contg. Pb and  $H_2SO_4$ ; the air is dried and is then heated before again being brought into contact with the plates. This treatment serves to prepare the plates for shipment and storage. An app. is described.

**Noncorrodible battery terminals.** CHARLES T. HIXSON (one-fourth each to Willard W. Campbell and Henry E. Pischel). U. S. 1,715,599, June 4. In making terminals which are resistant to electrolyte and fumes, Pb and Sb are heated to redness, powdered glass is added to the molten mass at such temp., with stirring, and the mixt. is molded.

**Galvanic cells.** NEUFELDT & KUHNKE, G. M. B. H. Ger. 475,764, Apr. 7, 1927. C electrodes are impregnated with depolarizing material by soaking them successively with 2 sep. solns., the second soln. having a reducing action on the first. Thus, the first soln. may contain a high-valent Mn compd. and the second soln. a low-valent Mn compd. such as  $MnCl_2$ .

**Galvanic cell.** PÖRSCHKE ELEKTRIZITÄTS-GES. M. B. H. 476,222, Dec. 30, 1925. In a galvanic cell having a pos. electrode of  $CuO$ , the neg. electrode is supported by one or more bodies of porous ceramic material arranged so as to interpose between the electrodes. The purpose of this arrangement is to accelerate the regeneration of the pos. electrode, which is effected by pouring away the electrolyte, removing the neg. electrode and heating. The electrolyte absorbed in the porous material then evaps. rapidly and accelerates the regeneration.

**Tanks for galvanic baths.** ALBERT BUTZIGER. Fr. 654,735, Mar. 27, 1928.

**Selenium cells.** JOHN NEALE. Fr. 655,034, May 31, 1928.

**Lead-zinc accumulators.** ADOLFO POUCHAIN. Ger. 475,569, May 20, 1927; Fr. 653,958, May 7, 1928. In a method of working an elec. Pb-Zn accumulator, the electrolyte contains 80 g. free acid per l. at the end of each complete discharge and 280 g. at the end of each complete charge. A suitable cell contains 1000 cc. water, 80-150 g.  $H_2SO_4$ , 450-650 g.  $ZnSO_4$  and 15-30 g.  $Al_2(SO_4)_3$ .

**Device for the correct filling of accumulators.** JEAN L. M. FRÉJACQUES. Ger. 476,795, Oct. 21, 1927.

**Accumulator plates.** I. G. FARBERIND. A.-G. (George Kränzlein and Richard K. Müller, inventors). Ger. 476,344, June 1, 1927. Addn. to 475,242. The method of Ger. 475,242 (C. A. 23, 3173) is modified by conducting the electrolysis in an alk bath. Plates of Pb-Na alloy on a framework of Pb can be so treated. A higher c. d. is applied than in Ger. 475,242, e. g., 15-25 amps./sq. dm.

**Accumulator plates and gratings.** WILHELM PETRI. Ger. 476,798, Aug. 11, 1927. Details of construction are given.

**Drying negative accumulator plates.** ERICH SIEG and LEOPOLD GRÄFENBERG. Ger. 476,281, Dec. 29, 1927. The plates are stored in water or other liquid in the drying chamber until it is required to dry them, whereupon the liquid is expelled by evacuating the chamber or by supplying an inert gas.

**Alloy for accumulator plates.** METALLGES. A.-G. Ger. 476,259, Mar. 19, 1927. The frame supporting the active mass is made from a Pb-Li alloy contg. up to 2% Li with or without an addn. up to 1% of Na, K or Rb, which improves the hardness, and (or) an addn. up to 1% of Ca, Ba, Sr or Mg, which enhances the toughness. A suitable alloy contains Pb 99.33, Li 0.02, Na 0.3 and Ca 0.35%.

**Electrodeposition of chromium.** FIRMA WILHELM STEINHORST. Ger. 476,264, Oct. 21, 1927. In the electrodeposition of Cr, the injurious effects on the product of the  $H$  simultaneously evolved are avoided by treating the object on which the metal is to be deposited, before, during or after the deposition, with  $O_3$ . The treatment may be accelerated by simultaneous irradiation with ultra-violet light.

**Chromium plating.** ALBERT BUTZIGER. Fr. 654,734, Mar. 27, 1928. Cast Fe contg. 1% or more of C, or 0.5% or more of P is plated with Cr by suspending the Fe for some mins., in the absence of any current, in a bath contg. the Cr soln. The same effect is obtained by submitting the Fe to the action of a current for a few mins. before plating.

**Cadmium plating.** THE GRASSELLI CHEMICAL CO. Fr. 654,850, May 25, 1928. A small quantity of a Ni salt is added to a Cd electrolytic bath to give brilliant hard deposits of Cd. An example of a suitable bath contains NaCN 120, Cd hydrate 48,  $Na_2SO_4$  60, crystd.  $NiSO_4$  1.5, turkey red oil or sulfonated castor oil 12 g. Cf. C. A. 22, 3847.

**Electroplating plant.** INTERNATIONAL COPPERCLAD CO. Ger. 476,106, May 29,

1927. A frame, movable along the cell, carries a no. of anodes and cathodes connected to a pair of contact shoes, which move, resp., along the pos. and neg. bus bars.

**Electroplating apparatus.** WESLEY F. HALL (to Hanson-Van Winkle-Munning Co.). U. S. 1,715,357, June 4. Structural features.

**Electroplating apparatus.** NICHOLAS P. DICESARE (to Kohler Co.). U. S. 1,715,411, June 4. Structural features.

**Electrolyte for electrolytic rectifier.** AMBROS GALETZKA. Ger. 476,610, Jan. 21, 1926. The electrolyte consists of a mixt. of  $\text{NH}_4\text{HCO}_3$  and  $(\text{NH}_4)_2\text{PO}_4$  solns. with addn. of a small quantity of alkali lye.

**Electrolytic cell.** FRANZ GERLACH. Swiss 130,897, Apr. 4, 1927. A cell for the decompn. of alkali chlorides has a Hg or amalgam cathode.

**Electrolytic vat.** PAOLO PESTALOZZA. Fr. 653,300, Apr. 21, 1928. A vat for the electrolysis of salts such as alkali chlorides is divided into 2 compartments having a bottom inclined both in the transversal and longitudinal sense; it has a single opening at the lowest point of the sepg. wall connecting both, and an overflow pipe at the lowest point of the vat for the discharge of the densest cathode liquid. Arrangement of the envelopes surrounding the cathode elements is also described.

**Amalgam tank for the electrolysis of chlorides.** I. G. FARBERIND. A.-G. Fr. 654,417, May 18, 1928.

**Electrolytic gas generators.** ATELIERS DE CONSTRUCTION OERLIKON. Fr. 654,922, May 29, 1928. Construction of gas collectors is given.

**Electrolytic apparatus for the production of hydrogen and oxygen.** "MONTECATINI" SOC. GENERALA PER L'IND. MINERARIA ED AGRICOLA. Fr. 654,289, May 14, 1928.

**Hydrogen peroxide.** I. G. FARBERIND. A.-G. Fr. 654,592, May 23, 1928. In the production of  $\text{H}_2\text{O}_2$  by the cathodic reducing of O, the current of O or gas contg. O required for the electrolysis vat is employed at the same time for the concn. or distn. of the soln. of  $\text{H}_2\text{O}_2$  produced in the vat.

**Acetylene.** I. G. FARBERIND. A.-G. Fr. 653,505, Apr. 27, 1928.  $\text{C}_2\text{H}_2$  is formed from coke-oven gas by passing it over a Ni catalyst to convert the CO to  $\text{CH}_4$  and by treating the resulting mixt. in an elec. arc. The heat of the gas from the elec. arc is used to heat the gas going to the catalyst.

**Refining antimony.** NORDDEUTSCHE AFFINERIE (Heinrich Roscher, inventor). Ger. 476,619, July 19, 1927. See Brit. 294,143 (C. A. 23, 1827).

**Pure alumina.** ELEKTRIZITÄTSWERK LONZA. Swiss 130,694, Aug. 4, 1927. Al ores are reduced thermoelectrically and an oxidizing atm. is applied continuously to the smelt to produce pure  $\text{Al}_2\text{O}_3$ .

**Electrometallurgy.** TURE R. HAGLUND. Ger. 475,735, Oct. 24, 1926. In extg. metals or alloys by heating briquets formed of oxide or oxide ore and carboniferous reducing material with slag in an elec. furnace, one part of the total reducing material (about 25%) is contained in the briquets while the other part is freely mixed among them in granular form. Cf. C. A. 23, 3173.

**Removing burrs from the cutting edges of tools.** GEBR. FUNKE A.-G. Ger. 476,757, Mar. 7, 1928. Addn. to 456,720. The burrs are removed electrochemically after the manner of the prior patent. The tools are plunged into a conducting bath of molten salts such as  $\text{BaCl}_2$  or  $\text{KCl}$  and serve as the anode while the bath container or an immersed conducting body serves as the cathode.

**Cathodes for making compounds containing active oxygen.** I. G. FARBERIND. A.-G. Fr. 654,881, May 26, 1928. The cathodes used for the production of compds. contg. active O are protected from corrosion by soaking with Hg either continuously or from time to time. The soaking may be accomplished by electrolytic pptn. of Hg on the cathode.

**Electrical gas-purifying plant.** LOUIS TOCCO and HENRY G. RYS. Fr. 652,855, Apr. 2, 1928.

**Electrical device for removing small solid particles from gases.** METALLGESELLSCHAFT A.-G. Ger. 476,794, Jan. 19, 1927. Addn. to 446,008.

**Apparatus for activating gases with electric waves of high or low frequency.** PAUL E. H. MARDULYN. Fr. 654,732, Mar. 27, 1928.

**Calcium arsenate.** PAUL E. H. MARDULYN. Fr. 654,733, Mar. 27, 1928. Ca arsenate is prepd. by treating arsenical pyrites or mispickel in elec. rotating, concentric furnaces to obtain arsenious anhydride, which, mixed with  $\text{CaO}$ , gives Ca arsenite; the latter is transformed into Ca arsenate by O activated in the app. of Fr. 654,732 (cf. preceding abstr.).

**Dewatering slimes by electroosmosis.** STETTINER PORTLAND-CEMENT-FABRIK. Ger. 476,144, May 18, 1921. The slime is fed under pressure into a vertical tube of

uniform cross section, on opposite sides of which the anode and the permeable cathode are arranged. The lower end of the tube is closed by a movable disk having an outlet aperture which is brought into register with the tube at suitable intervals.

**Furnaces.** PIERRE F. VIANDON. Fr. 654,676, May 24, 1928. An elec. furnace for the reduction of ores in a single fusion is described.

**Electric furnace.** DET NORSK AKTIESELSKAB FOR ELEKTROKEMISK INDUSTRI NORSK INDUSTRI-HYPOTEKBANK. Ger. 475,732, Oct. 13, 1921. The vertically arranged electrodes are hollow and are filled with a calcined conducting material which bridges the gap and forms the heating resistance. The furnace is arranged so that the material to be heated is loaded around the electrodes and the column of material in the gap.

**Electric furnaces.** WILHELM HAMMER. Fr. 654,053, May 10, 1928. The heating current is induced in a fusion bath surrounding the chamber or article to be heated Cf. C. A. 23, 1066.

**Electric furnace for the treatment of metals.** PITTSBURGH RESEARCH CORP. Fr. 654,432, May 18, 1928.

**Annular rotating electric furnace for ores, etc.** PAUL E. H. MARDULYN. Fr. 654,731, Mar. 27, 1928.

**Electrically heated furnace for melting metals such as aluminum.** STEPHAN SCHNEIDER (to Westinghouse Elec. & Mfg. Co.). U. S. 1,715,678, June 4. Various details are specified of a furnace comprising a melting pot to which an inert or reducing gas may be supplied.

**Induction furnace for melting copper, etc.** EMIL F. RUSS. Fr. 653,909, May 8, 1928.

**Electric induction furnace.** ELECTRIC FURNACE CO., LTD. Fr. 654,949, May 29, 1928.

**Electric induction furnace.** MARCEL FOURMENT. Ger. 476,098, Feb. 12, 1926 See Brit. 265,548 (C. A. 22, 196).

**Mounting and packing for electrodes of electric furnaces.** JAMES E. McLAUGHLIN (to Brown Co.). U. S. 1,715,376, June 4. Structural features.

**Replenishing furnace electrodes.** CARL BECKER. Austrian 112,969, Dec. 15, 1928. Manipulative and structural features are described.

**Device for raising the electrode in an electric smelting furnace.** DEMAG A. G. Ger. 475,733, July 17, 1925.

**Electric resistance heater.** HENRY A. ZIOLA (to Swartzbaugh Mfg. Co.). U. S. 1,715,690, June 4. Structural features.

**Electric resistance heating unit.** WILLIAM E. DUERSTEN (to Globar Corp.) U. S. 1,715,824, June 4. Structural features.

**Electric resistance element.** CHRISTIAN DANTSIZEN (to General Electric Co.). U. S. 1,717,193, June 11. A resistance element suitable for use as in "grid leaks" comprises a fibrous support such as paper with a uniform continuous graphite coating retained on the support without a binder in its superficial interstices.

**Electrical resistances.** NAAMLOOZE VENNOOSTCHAP PHILIPS' GLOEIILAMPEN-FABRIEKEN. Fr. 653,880, May 4, 1928. A conducting material such as C is mixed with a phenol-aldehyde condensation product or cellulose acetate to form elec. resistances.

**Electric resistors.** HEINRICH TRAUN & SÖHNE, VORMALS HARBURGER-GUMMI KAMM-COMPAGNIE. Ger. 476,982, Nov. 5, 1926. Finely powd. PbO is mixed with such plastic masses as rubber.

**High resistance electrical unit.** GEORGE A. WELLS. U. S. 1,715,879, June 4. A base of unglazed porcelain material substantially impervious to moisture and ordinary acids carries an attenuated coating of dry elec. conducting carbonaceous material, and has a resistance value of great constancy for extended periods of continuous operation.

**Electrical condenser.** SAMUEL RUBEN. U. S. 1,715,789, June 4. Al electrodes coated with Al sulfide are used in close contact with CuS. Cf. C. A. 23, 3414.

**Condenser for zinc vapors from electric furnaces.** FILIP THARALDSEN. U. S. 1,715,960, June 4. A condenser is described comprising a block of deep relatively narrow parallel channels spaced apart and inclined downwardly from the furnace chamber to a common container for collecting the products of combustion.

**Electric control or recording apparatus for carbon dioxide meters, draft gages, etc.** FREDERICK D. PORTER and NELSON HISS (to Combustion Control Co.). U. S. 1,715,511, June 4.

**Mercury-vapor rectifier.** AKTIEN GESELLSCHAFT BROWN, BOVERI & CIE. Swiss 130,560, Feb. 3, 1928. The anode has a protecting cover.

**Electrical calorimeter.** CHRISTIAN HÜLSMEYER. Ger. 476,361, Aug. 24, 1926.

**Plastic conductive composition.** ARLIE W. SCHORGER (to Burgess Battery Co.). U. S. 1,717,171, June 11. A compn. suitable for forming cathodes of flat elec. dry batteries comprises graphite 60, rosin 30, Montan wax 5 and linseed oil 5%.

**Luminous neon tubes.** BATTISTA DEROSI and AGOSTINO D. DEROSI. Fr. 654,544, May 22, 1928. The electrodes are formed of elements having a low at. wt. such as alkali, alk. earth or earth metals.

**Wire filaments.** COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS. THOMSON-HOUSTON. Fr. 653,805, May 3, 1928. A non-metallic element such as C is combined with a metal filament such as W by exposing the filament at incandescent heat in a chamber into which a gas contg. C is introduced. The duration of the exposure is controlled according to the increase of resistance of the filament.

## 5—PHOTOGRAPHY

C. E. K. MEES

New uses for Cd [as bromide in light-sensitive gelatin films] (FRANK) 18.

**Photographic processes.** ERNST BURI. Ger. 475,619, Nov. 15, 1927. A gelatin surface which has been exposed and soaked is dusted simultaneously or in sequence with coloring materials which have differing actions thereon. The materials are so chosen that some act more strongly on the highly soaked part of the surface and others more strongly on the less soaked parts.

**Photographic process.** SCHERING-KAHLBAUM A.-G. (Wolfgang Schultz, inventor). Ger. 475,816, Dec. 31, 1927. Two-layer photographic plates for taking direct positives have the layers sep'd. by a lamina of material, e. g., resin or casein, which is dissolved in or decomposed by the usual baths following the exposure.

**Photographic processes.** SOCIÉTÉ DU FILM EN COULEURS KELLER-DORIAN. Ger. 475,655, Dec. 3, 1926. Elements are attached to the surface of cylinders so that their impress remains on light-sensitive films passed thereover after the film is developed.

**Photographic processes.** SOCIÉTÉ CIVILE POUR L'ÉTUDE DE LA PHOTOGRAPHIE ET DE LA CINÉMATOGRAPHIE EN COULEURS. Ger. 475,656, April 8, 1927. A method of producing lenticular film bands is described.

**Sensitive material for color photography.** SOC. CIVILE POUR L'ÉTUDE DE LA PHOTOGRAPHIE ET DE LA CINÉMATOGRAPHIE EN COULEURS. Ger. 476,499, June 4, 1927. See Brit. 289,864 (C. A. 23, 782).

**Photographic prints.** LUXOR-FILM, G. m. b. H. Fr. 653,670, May 1, 1928. Detailed prints are obtained on bichromate colloid layers with a short exposure ( $\frac{1}{4}$  to  $\frac{1}{4}$  sec.) by treating the layer after printing with cold supersatd. water vapor, which may contain weak volatile acids, such as AcOH or CO<sub>2</sub>. The prints are developed directly in cold water, and colored if desired, or they may be subjected first to an addnl. exposure, which may be through the support during or after the vapor treatment. Layers are described which are sensitized by a 3-10% soln. of bichromate, followed by treatment while still wet, with pure water or a weak soln. of bichromate.

**Composition photographs.** ROY J. POMEROY (one-half to Paramount Famous Lasky Corp.). U. S. 1,715,510, June 4. Optical features.

**Photographic plates.** I. G. FARBENIND. A.-G. Fr. 654,989, May 30, 1928. See Ger. 472,890 (C. A. 23, 2895). Photographic plates are rendered free from halo by the application on the reverse side of the plates of an alk. soln. of casein to which has been added a dye such as acid black 2B, nigrosine D or lampblack and CH<sub>2</sub>O.

**Photographic films.** PAUL J. M. LÉBOUCHER. Fr. 652,735, Sept. 20, 1927. To prevent accumulation of electrostatic charges on photographic and cinematographic films, an adherent coating of animal or vegetable albumen, particularly egg albumen, is formed thereon.

**Films for color cinematography.** ALEX PILNY and H. SCHÄRRER. Swiss 131,124, Oct. 29, 1927.

**Apparatus for treating cinematographic film surfaces.** LÉON GILLON and GRATIOUT-LET MAURICE. Fr. 653,955, May 7, 1928.

**Working up old cinematograph films.** HANS PICK. Austrian 112,989, Dec. 15, 1928. The gelatin emulsion is removed with a warm, very dil., soln. of NaOH and the

films are then steeped in a cold *N* soln. of NaOH in order to dissolve the albumen layer used to affix the emulsion to the celluloid. The Ag is recovered from the gelatin soln. obtained in the first step by coagulating, etc.

## 6—INORGANIC CHEMISTRY

A. R. MIDDLETON

The preparation of barium. A. GUNTZ. *Chimie & industrie* Special No., 458-62 (Feb., 1929); cf. G. and Benoit, *C. A.* 18, 2654.—By slowly heating Ba amalgam *in vacuo* to 1150°, a metal was obtained contg. Ba 98.35, Hg 0.83, Fe 0.40, Fe<sub>2</sub>O<sub>3</sub> and SiO<sub>2</sub> 0.05%. Hg and Fe could not be completely eliminated. BaH<sub>2</sub> was obtained by heating Ba amalgam in a current of H; to obtain the BaH<sub>2</sub> pure, the amalgam must be heated progressively and very slowly in H, avoiding fusion, or most of the Hg must be driven off before passing H. On heating the BaH<sub>2</sub> to fusion, Ba is obtained, contaminated with a little Fe from the tube; it is readily purified by sublimation. BaO and Mg heated *in vacuo* in a mild-steel crucible with the end of a water-cooled steel tube placed near the mouth of the crucible give in the crucible a black mass contg. Ba<sub>2</sub>O, and on the end of the water-cooled tube a mixt. of Ba and Mg. Mg reacts with BaO to form chiefly Ba<sub>2</sub>O, which is unstable and which dissociates at high temp. to give Ba; the latter in turn reacts with the MgO formed; an equil. is established so that the proportion of the two metals deposited varies with exptl. conditions. It was concluded from these results that Ba can be prepd. very simply by heating BaO to a high temp. with a compd. having a high heat of oxidation; numerous expts. showed that the best metal is Al, which has a very low vapor tension at 1350°, the temp. required to obtain about 50 g. Ba per operation. Pure Ba has a white metallic luster (when it contains N it is yellow), m. about 850°, has d. 3.78, is volatile *in vacuo* and can thus be sublimed, and readily burns to BaO when heated. When added to one of its fused salts it is rapidly dissolved with formation of sub-salts; BaCl, BaBr, BaI and BaF were thus obtained. The following *heats of formation* were detd.: BaO 134.0, Ba<sub>2</sub>O 149.5, BaCl, 204.3, BaCl 110.4, Ba(NH<sub>2</sub>)<sub>2</sub> 80.2, BaH<sub>2</sub> 40.9, Ba<sub>3</sub>N<sub>2</sub> 31.3 cal. It is unaffected by dry CO<sub>2</sub>; when hot it readily absorbs H or N to form BaH<sub>2</sub> or Ba<sub>3</sub>N<sub>2</sub>, resp.; below 28° it combines with NH<sub>3</sub> gas to form Ba(NH<sub>2</sub>)<sub>2</sub>, which very slowly decomps. in the cold with evolution of H and formation Ba(NH<sub>2</sub>)<sub>2</sub>; when heated in NH<sub>3</sub> gas it forms Ba(NH<sub>2</sub>)<sub>2</sub>, which can give the imide, the reaction being reversible. A bibliography of 46 references is included.

A. PAPINEAU-COUTURE

The Buff compounds and Bunsen salt. FRANZ HÖLZL. *Monatsh.* 51, 157-68 (1929).—Buff in 1854 observed that by satn. of an alc. soln. of H<sub>4</sub>Fe(CN)<sub>6</sub> with HCl substances of the formulas (C<sub>2</sub>H<sub>5</sub>)<sub>4</sub>Fe(CN)<sub>6</sub>·2C<sub>2</sub>H<sub>5</sub>Cl·6H<sub>2</sub>O, (C<sub>2</sub>H<sub>5</sub>)<sub>4</sub>Fe(CN)<sub>6</sub>·6H<sub>2</sub>O and (C<sub>2</sub>H<sub>5</sub>)<sub>4</sub>Fe(CN)<sub>6</sub> were formed. It is now proved that these compds. suffer no sapon. in aq. soln. and are not esters or ethers. The dissoen. is exactly analogous to that of the Bunsen salt (NH<sub>4</sub>)<sub>4</sub>Fe(CN)<sub>6</sub>·2NH<sub>4</sub>Cl or Fe(CN)<sub>6</sub>·H<sub>4</sub>(NH<sub>2</sub>)<sub>4</sub>·2NH<sub>3</sub>·HCl thus: Fe(CN)<sub>6</sub>·H<sub>4</sub>(C<sub>2</sub>H<sub>5</sub>OH)<sub>4</sub> + 2C<sub>2</sub>H<sub>5</sub>OH·HCl. Hence the salt nature is indicated. Vapor pressure measurements prove that H<sub>4</sub>Fe(CN)<sub>6</sub> forms 4 compds. with EtOH, 1 mol. of the acid with 4, 3, 2 and 1 mols. of alc. The compds. are primary, secondary, tertiary and quaternary salts of the tetrabasic acid with the base alcohol, or they are the ethoxonium salts of the related acids.

G. L. CLARK

A new method for the preparation of the fluorine oxide. P. LEBEAU AND A. DAMIENS. *Compt. rend.* 188, 1253-5 (1929).—The authors have previously shown that in the electrolysis of a bath of KHF<sub>2</sub> in the presence of a little H<sub>2</sub>O, a gas contg. F<sub>2</sub>O contaminated with O<sub>2</sub> was liberated (*C. A.* 22, 200). Efforts to prep. the pure gas led to the discovery that most of the O<sub>2</sub> is retained by the soln. when F<sub>2</sub> is passed at the rate of 1 l. an hr. through a 2% soln. of NaOH. The O compd. is unstable and is strongly oxidizing. The final result is expressed by: 2 F<sub>2</sub> + 2 NaOH = 2 NaF + F<sub>2</sub>O + H<sub>2</sub>O. The gas was collected over H<sub>2</sub>O and then liquefied by liquid air. By fractionation a product of purity greater than 97% was obtained. It b. about -167° and freezes below -190°.

H. F. JOHNSTONE

The reaction between cuprous sulfide and metallic lead, tin and especially zinc at the melting point. CARL FRICK. *Metall u. Erz* 24, 465-72 (1927); *Chem. Zentr.* 1928, I, 114.—Upon melting Cu<sub>2</sub>S with Zn, Sn or Pb, a part of the Cu was freed and the S combined with the other metals to give metallic sulfides upon cooling the melt. PbS and SnS form eutectics, ZnS and Cu<sub>2</sub>S only mech. mixts. with Cu<sub>2</sub>S. Cu and Zn or Sn form an alloy within the Cu<sub>2</sub>S regulus. Cu and Pb do not alloy.

F. P. G.

**Amphoteric hydroxides, their aqueous solutions and crystalline compounds.** VIII. GERHART JANDER, DIETRICH MOJERT AND THEODOR ADEN. *Z. anorg. allgem. Chem.* 180, 129-49(1929); cf. C. A. 23, 3147.—A summary of work on simple, isopoly and heteropoly tungstates. Several tungstates were prepd., analyzed and investigated by diffusion and optical absorption expts. Particular attention is given the *parawolframate*,  $\text{Na}_2\text{W}_2\text{O}_7$ , a new compd. The *arsenic polywolframate*,  $\text{H}_2[\text{As}(\text{W}_2\text{O}_7)_2]$  aq., was studied also.

WILLIAM E. VAUGHAN

**Studies in the preparation of pure metallic tungsten.** IV. The degree of hydration of tungstic acid. YOSHIO NAKAZAWA AND TATSUZO OKADA. *Elec. Rev.* 17, 89-94 (1928).—To obtain tungstic acid suitable for the prepn. of pure metallic W, and to study the relation of the method of the formation of tungstic acid to its properties the following methods of prepn. were used. (1) Conc'd. HCl soln. of the acid was evapd.; this gave yellow  $\text{WO}_3 \cdot \text{H}_2\text{O}$  in crystals  $3\mu$  in diam. (2) The conc'd. HCl soln. was dild. by passing  $\text{H}_2\text{O}$  vapor into it; finer yellow crystals of  $\text{WO}_3 \cdot \text{H}_2\text{O}$  were pptd., many of them measuring  $0.3\mu$  in diam. (3) The conc'd. HCl soln. was dild. to 7 *N* HCl with  $\text{H}_2\text{O}$  at ordinary temp.; a light yellow ppt. was formed in which the mean diam. of the particles was  $0.3\mu$ . The compn. varied, but water of hydration was greater than  $\text{WO}_3 \cdot 7\text{H}_2\text{O}$ . The acid resembles the white tungstic acid of Hüttig and Kerr. The first two acids can easily be filtered and washed and lose their  $\text{H}_2\text{O}$  only above  $180^\circ$ . They are suitable for prepn. of pure W. The acid prepd. by the 3rd method cannot be readily filtered and washed and is unsuitable for the prepn. of the metal.

K. SOMEYA

**A study of the composition of sodium bismuth tartrate.** JOHN H. YOE AND JOHN H. MORE. *J. Am. Pharm. Assoc.* 18, 450-9(1929).—The specimens of Na Bi tartrate used had been prepd. by treating  $\text{Bi}(\text{OH})_3$  with NaOH and tartaric acid and pptg. with 95% EtOH. With small amt. of  $\text{H}_2\text{O}$  it forms a gel, which dissolves in more  $\text{H}_2\text{O}$ . The salt so treated remains in soln., however much dild. If treated at once with a large excess of  $\text{H}_2\text{O}$  it forms a cloudy soln. The soln. is alk. to phenolphthalein. Bi was detd. as  $\text{Bi}_2\text{S}_3$  and as Bi by the hyposulfite method. The mean values obtained were, resp., 73.26 and 73.24%. Tartaric acid was detd. by a modification of the method used by Warren (C. A. 19, 1756). The mean values for 3 lots were 14.40, 14.38 and 13.45%  $\text{C}_4\text{H}_6\text{O}_6$ . Mean of all was 14.07 but 14.92 when corrected for soly.  $\text{CO}_2$  detns. gave 0.47, 0.29 and 0.52%, indicating small quantities of  $\text{Na}_2\text{CO}_3$  or  $\text{NaHCO}_3$ . The compn. is evidently Na tetra-Bi tartrate.

## 7—ANALYTICAL CHEMISTRY

W. T. HALL

**Acidimetry and alkalimetry in presence of a few fluorescent indicators, especially umbelliferone.** Y. VOLMAR AND E. WIDDER. *Chimie & industrie Special No.*, 160-3 (Feb., 1929).—The method consisted in titrating the soln. in a quartz (or thin Pyrex glass sufficiently transparent to ultra-violet light) Erlenmeyer flask illuminated by light from a Hg arc filtered through a Wood screen, the titration being carried out in a dark room. Temp. has a slight retarding effect. The intensity of the fluorescence is generally higher in aq. than in alc. solns.; with umbelliferone the max. intensity was observed at about 50% alc. by vol. As little indicator as possible should be used to make the end point sharp. Umbelliferone is the most sensitive indicator, 1 drop of 0.001% soln. giving a clear end point; acridine requires 10 times as much, quinine 100 times and fluorescein 500 times. For titrating strong acids and alkalis at concns. of *N* to 0.1 *N*, fluorescent indicators offer no advantage over the ordinary indicators; but at very high dilns. (0.001 *N*) titrating can be carried out as accurately with umbelliferone as they can be with *N* solns. and ordinary indicators. For org. acids with very dil. solns. umbelliferone gives as accurate results as for strong acids, but the other fluorescent indicators offer no advantages. Boric acid can be titrated more accurately

with umbelliferone (especially in presence of glycerol).  $\text{NaH}_2\text{PO}_4$  is clearly acid to umbelliferone, and less acid to quinine, acridine and fluorescein;  $\text{Na}_2\text{HPO}_4$  is neutral to umbelliferone and quinine, and alk. to acridine and fluorescein;  $\text{Na}_3\text{PO}_4$  is alk. to all the fluorescent indicators. With medium concns. (0.1–0.01 *N*)  $\text{NH}_3$  is best titrated with acridine, with an accuracy equal to that of the titration of strong alkalis; at high dilns. (0.001 *N*) umbelliferone is the best indicator. Acridine and umbelliferone give as accurate results in the titration of alk. carbonate as for strong alkalis. Alkali borates and cyanides can be titrated like strong bases, with either umbelliferone or acridine, but not as accurately. Alkali salts of volatile acids can be titrated with  $\text{H}_2\text{SO}_4$ , either directly by boiling and then by cooling to observe the fluorescence, or by removing the liberated  $\text{AcOH}$  by entrainment with steam. A. PAPINEAU-COUTURE

Zinc uranyl acetate as reagent for sodium. I. M. KOLTHOFF. *Chem. Weekblad* 26, 294–8(1929); cf. *C. A.* 21, 1773; 22, 2898.—A summary of the earlier expts.

E. SCHOTTE

Gravimetric determination of tungsten in the presence of vanadium. A. JILEK AND J. LUKÁŠ. *Chimie & industrie Special No.*, 166–7(Feb., 1929); *Collection Czechoslov. Chem. Comm.* 1, 263–74.—If the soln. contg. W and V is alk., neutralize with  $\text{HCl}$ , add 1 cc. concd.  $\text{HCl}$  and 0.5 g.  $\text{NH}_4\text{OH} \cdot \text{HCl}$ , dil. to 100 cc., boil till the soln. turns blue, add 1 cc. concd.  $\text{HCl}$ , dil. to 200 cc., add 10 cc. of a 2% soln. of  $\text{As}_2\text{O}_3$ , heat to boiling, add quickly a 2% soln. of quinine- $\text{HCl}$  with stirring, let stand 12 hrs. with occasional stirring, filter, wash with 200 cc.  $\text{H}_2\text{O}$  contg. 2 cc. concd.  $\text{HCl}$ , 2 cc. of 2%  $\text{As}_2\text{O}_3$  soln. and 4 cc. of 4% quinine- $\text{HCl}$ , wash with 200 cc. of  $\text{H}_2\text{O}$  contg. 2 cc. concd.  $\text{HCl}$  and 4 cc. of 4% quinine- $\text{HCl}$ , dry, ignite and weigh as  $\text{WO}_3$ . The method is suitable for not more than 0.2 g. of  $\text{WO}_3$  and 0.2 g. of  $\text{V}_2\text{O}_5$ . If more than 0.1 g. of either is present, it is advisable to make a double pptn. if V is to be detd. in the filtrate. In the absence of V, the reduction with  $\text{NH}_4\text{OH} \cdot \text{HCl}$  can be omitted. V can be detd. in the filtrate as follows: evap. to dryness, add 10 cc. of concd.  $\text{H}_2\text{SO}_4$  and a little  $\text{CuO}$  or  $\text{CuSO}_4$ , evap. to white fumes, dil., reduce by boiling with  $\text{H}_2\text{SO}_4$ , boil off the excess, ppt. Cu and As with  $\text{H}_2\text{S}$ , filter, wash, acidify the filtrate with  $\text{H}_2\text{SO}_4$ , boil off  $\text{H}_2\text{S}$ , make slightly alk. with  $\text{NaOH}$ , oxidize to vanadate with a 30%  $\text{H}_2\text{O}_2$  soln. boiling till the excess is destroyed, ppt. with  $\text{Hg}_2(\text{NO}_3)_2$ , filter, ignite and weigh as  $\text{V}_2\text{O}_5$ .

Sn, Sb, Ni, Co, Cd, Cu, Zn, Mg, Pb, Al, Fe, Bi and Mn from one original soln. and dispensing with complex reagents is described.

H. L. D.

Determination of phosphorus in steels containing vanadium. ED. ROUSSEAU. *Chimie & industrie Special No.*, 147–50(Feb., 1929).—The following procedures are recommended: *High-speed tool steels*.—Dissolve 1 g. in 15 cc. of 1:1  $\text{HCl-HNO}_3$ , add 20 cc. of boiling  $\text{H}_2\text{O}$ , filter, wash slightly with hot 5%  $\text{HCl}$ , evap. to 8–10 cc., add 10 cc. of 12 *N*  $\text{HNO}_3$ , boil a few mins., add 2–3 cc. of 10%  $\text{NaNO}_2$  and immediately after 30–5 cc. of molybdate reagent, stir, let stand a few mins. and centrifuge. *High Cr steels contg. V*.—Treat 1 g. with 20 cc.  $\text{HCl}$  and 3–4 g.  $\text{KClO}_3$ , first cold, then hot, evap. to about 10 cc., add  $\text{KMnO}_4$  to abundant pptn. of  $\text{MnO}_2$ , boil a few mins., dissolve  $\text{MnO}_2$  with a little  $\text{NaNO}_2$ , wash slightly, conc. to 10 cc., add 10 cc. of 12 *N*  $\text{HNO}_3$  and proceed as above. *V steels sol. in 6 N HNO<sub>3</sub>*.—Dissolve 1 g. in 15 cc. of 6 *N*  $\text{HNO}_3$ , boil a few mins., add 2–3 cc.  $\text{NaNO}_2$  and immediately add the molybdate reagent, and centrifuge. By following these instructions the V at the time of pptn. is in the vanadyl state and the temp. is not above 65°, below which vanadyl salts do not seem to oxidize to vanadic acid.

A. PAPINEAU-COUTURE

Mercurimetric studies. I. Titrimetric determination of the cyanide ion. B. VOTOČEK AND J. KOTRBA. *Collection Czechoslov. Chem. Comm.* 1, 165–72(1929); *Chimie & Industrie Special No.*, 164, (Feb., 1929).—A continuation of V.'s work on the use of  $\text{Hg}(\text{NO}_3)_2$  in titration (cf. *C. A.* 12, 2177; 17, 1769). Na nitroprusside is used as an indicator, forming with the excess  $\text{Hg}^{++}$  an opalescent turbidity due to a ppt. of  $\text{HgFe}(\text{CN})_5\text{NO}$ . A correction must be made to allow for the excess  $\text{Hg}^{++}$  necessary to form the turbidity. Alk. cyanides are detd. by adding an excess of 0.1 *N*  $\text{Hg}(\text{NO}_3)_2$  to convert the  $\text{CN}^-$  into un-ionized  $\text{Hg}(\text{CN})_2$ , then a known vol. of 0.1 *N*  $\text{NaCl}$  to convert the excess  $\text{Hg}^{++}$  into  $\text{HgCl}_2$ , and titrating back the excess  $\text{Cl}^-$  with more 0.1 *N*  $\text{Hg}(\text{NO}_3)_2$ . The results are excellent.  $\text{CN}^-$  and  $\text{Cl}^-$  are detd. in the presence of each other by titrating, in one sample, both  $\text{CN}^-$  and  $\text{Cl}^-$ ; in a second

sample, HCHO is added to remove the  $\text{CN}^-$  as glycolic nitrile,  $\text{CH}_2\text{OHCN}$ , and  $\text{Cl}^-$  alone is titrated. Nitroprussides are detd. by pptn. as  $\text{HgFe}(\text{CN})_5\text{NO}$ , followed by soln. in a known vol. of 0.1 *N* NaCl and by titration of the excess  $\text{Cl}^-$  by 0.1 *N*  $\text{Hg}(\text{NO}_3)_2$ .

J. H. REEDY

**Diphenylamine and diphenylamine blue.** A. THIEL. *Z. Elektrochem.* **35**, 274-8 (1929).—For the colorimetric detn. of  $\text{Ph}_2\text{NH}$  the best oxidizing agent is  $\text{Fe}_2(\text{SO}_4)_3$  in 18 *N*  $\text{H}_2\text{SO}_4$ . The color develops slowly in the cold or at  $100^\circ$  on a water bath in 5 mins. Longer heating has no effect. The color is const. for weeks at room temp. At least 100 moles of  $\text{Fe}_2(\text{SO}_4)_3$  is necessary. One cc. of 40 p. p. m. of  $\text{Ph}_2\text{NH}$  in 50%  $\text{H}_2\text{SO}_4$  oxidized by 9 cc. of satd.  $\text{Fe}_2(\text{SO}_4)_3$  in 50%  $\text{H}_2\text{SO}_4$  gives a measurable color in a 30 mm. layer; 1% of this can be detected. By this reaction the solubilities in water,  $\text{H}_2\text{SO}_4$  and salt solns. are detd.  $\text{Ph}_2\text{NH}$  is a weak base. The absorption spectrum of diphenylamine blue was detd. With moderate excess of oxidizing agent this is a time reaction. It is suggested that the  $\text{C}_6\text{H}_5\text{N}:\text{C}_6\text{H}_4\cdot$  radical by oxidation joins another such radical to give the product.

FOSTER DEE SNELL

**Determination of reducing sugars, especially dextrose, by alkaline copper solutions in the presence of hydrocyanic acid.** H. HÉRISSEY AND A. CHALMETA. *J. pharm. chim.* [8], **8**, 393-406 (1928).—Detn. of dextrose by Bertrand's method (1906) gives low results in the presence of HCN, for several reasons. Methods of obtaining accurate results are: (A) Rapid titration of the alk.-Cu soln. with the sugar soln. until decolorized. (B) Elimination of HCN (a) by complete evapn. on the water-bath; exact results are obtained with simple solns. of dextrose and HCN in pure  $\text{H}_2\text{O}$ . With complex mixts., e. g., crystd. amygdalin in contact for 5 days with  $\text{H}_2\text{O}$  and emulsin of almonds, evap. an aliquot vol. to one half, then restore the vol. with  $\text{H}_2\text{O}$ . Det. the sugar in this soln. by Bertrand's method after defecation with basic Pb acetate and after removing excess of Pb with  $\text{Na}_2\text{SO}_4$ ; (b) by passing a current of air through the simple soln. or through the complex mixt. for 5 hrs.; (c) by chem. means; ppt. HCN with excess of  $\text{AgNO}_3$ , filter, remove Ag with NaCl, filter and det. the sugar by Bertrand's method.

**Estimation of hydrogen.** SOC. INTERNATIONALE DES COMBUSTIBLES LIQUIDES (Deutsche Bergin A.-G. für kohle und erdolchemie, applicants in Germany). *Fr.* 653,137, April 20, 1928. H in gaseous mixts. is estimated by the measure of the pressure of H diffused through a diaphragm of Pd, Pt or Ir in the form of a small tube closed at one end, and the capacity of which is reduced as much as possible by an inert filling material, which may be formed by a lengthening of the metallic tubular connection to the manometer serving to measure the pressure. The measuring operation is carried out at a temp. of  $300-500^\circ$ .

## 8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIRER

**Dispersion of minerals.** A. N. WINCHELL. *Am. Mineral.* **14**, 125-49 (1929).—All of the reasonably accurate data on dispersion ( $\text{F-C}$  or  $\text{H}_\beta\text{-H}_\alpha$ ) are assembled in tabular form. The minerals are classified first in groups of increasing dispersion and then arranged in each group in the order of increasing refringence. A. M. BRANT

**An Illinois record copper erratic.** A. R. CROOK. *Am. Mineral.* **14**, 119-24 (1929).—Includes a list of the specimens of drift Cu found in Illinois with complete data.

A. M. BRANT

**An x-ray study of the domeykite group.** L. S. RAMSDALL. *Am. Mineral.* **14**, 188-96 (1929).—A series of artificial preps. made chiefly by fusion of Cu and As was in entire agreement with the Cu-As system diagram, which is known from pure Cu to Cu 70-As 30%, as shown by microscopic examn. and x-ray photographs. No constituents but  $\text{Cu}_3\text{As}$  and Cu-As solid solns. were found. *Whitneyite*,  $\text{Cu}_3\text{As}$ , was found to be a mixt. of algodonite and Cu-As solid soln. *Algodonite*,  $\text{Cu}_3\text{As}$ , is a definite compd., but is unstable at its m. p., breaking down into  $\text{Cu}_3\text{As}$  and Cu-As solid soln.

**Domeykite**,  $\text{Cu}_3\text{As}$ , is a definite compd., which is unstable at or near its melting point, undergoing a monotropic inversion to a dimorphous form which corresponds to the artificial  $\text{Cu}_3\text{As}$  compd. A. M. BRANT

**Note on hydrophilite**. CHESTER B. SLAWSON. *Am. Mineral.* 14, 160-1 (1929).—Artificial hydrophilite is probably orthorhombic with pseudo-tetragonal development; it has  $\alpha = 1.600$ ,  $\beta = 1.605$ ,  $\gamma = 1.613$ , all  $\approx 0.003$ . Polysynthetic twinning is characteristic. Positive biaxial interference figures were obtained on the wider lamellae. The inversion of  $\text{CaCl}_2$  to an isotropic form, described by Larsen, is thought to be due to the formation of a compd. with the immersion liquids. A. M. BRANT

**Loseyite**, a new Franklin mineral. L. H. BAUER AND HARRY BERMAN. *Am. Mineral.* 14, 150-3 (1929).—The compn. deduced from analysis is  $2\text{RCO}_3 \cdot 5\text{R}(\text{OH})_2$ , where  $\text{R} = \text{Mn}:\text{Zn}:\text{Mg} = 5:4:1$ . The mineral occurs as small lath-shaped bluish white crystals, loosely grouped in radiating bundles in cavities of a narrow vein of altered pyrochroite and susexite along with calcite and chlorophoenicite. It is monoclinic, elongated parallel to b, and biaxial +, with  $2V = 64^\circ$ ,  $Y = b$ ,  $\rho > v$ ,  $\alpha = 1.637$ ,  $\beta = 1.648$ ,  $\gamma = 1.676$ . The sp. gr. = 3.27, hardness = 3; cleavage was not detected. A. M. BRANT

**Mooreite**, a new mineral, and fluoroborite from Sterling Hill, New Jersey. L. H. BAUER AND HARRY BERMAN. *Am. Mineral.* 14, 165-72 (1929).—Clear glassy white crystals of mooreite and bluish white  $\delta$ -mooreite were associated with altered pyrochroite, rhodochrosite and zincite in a vein in the normal ore. The formulas assigned are: mooreite  $7\text{R}(\text{OH})_2 \cdot \text{RSO}_4 \cdot 4\text{H}_2\text{O}$ , where  $\text{R} = \text{Mg}:\text{Mn}:\text{Zn} = 4:1:2$ , and  $\delta$ -mooreite  $6\text{R}(\text{OH})_2 \cdot \text{RSO}_4 \cdot 4\text{H}_2\text{O}$ , where  $\text{R} = 5:3:4$ , resp. Mooreite is monoclinic, with perfect cleavage parallel to (010), hardness = 3, sp. gr. = 2.470. It is biaxial —, with  $2V = 50^\circ$ ,  $X = b$ ,  $Z \wedge c = 44^\circ$ ,  $\rho > v$ ,  $\alpha = 1.533$ ,  $\beta = 1.545$ ,  $\gamma = 1.547$ .  $\delta$ -Mooreite is granular, with imperfect cleavage, hardness = 3, sp. gr. = 2.665. It is biaxial —, with  $2V = 40^\circ$ ,  $\alpha = 1.570$ ,  $\beta = 1.584$ ,  $\gamma = 1.585$ . Fluoroborite in hair-like crystals coated the mooreite. The analyses given indicated the formula  $6\text{MgO} \cdot \text{B}_2\text{O}_3 \cdot 3(\text{F}_2 \cdot \text{H}_2\text{O})$ , the ratio of the  $\text{H}_2\text{O}$  to F being 2:3. It is uniaxial —, with  $\omega = 1.548$ ,  $\epsilon = 1.518$  and sp. gr. = 2.88, or when assocd. with zincite 1.547, 1.522 and 2.92, resp. X-ray spectrographs indicate that fluoroborite is hexagonal. A. M. BRANT

A unique formation of satin spar. V. G. HILLS. *Am. Mineral.* 14, 200-1 (1929).—In a mine at Skouriotissa, Cyprus, which had been closed for 1500 years, were found long, clear, hair-like crystals of selenite up to 13 ins. long. A. M. BRANT

The gold deposits of Colombia: the gold veins of Recreo. W. RINTISCH. *Abhandl. prakt. Geol. u. Bergwirtschaftslehre* No. 16, 37 pp. (1928).—Comprises the general geology of region and description of Au veins in department of Tolima, on Anaimé River. The origin of the deposits and methods of ore treatment are discussed. E. I. S.

**Important gold-cobalt occurrence**. W. F. H. DUDGEON. *S. African Mining Eng. J.* 40, 113 (1929).—A brief description of the Co-Au deposit on Krui River farm in the Middleburg district. The ore carries 3% Co and 10 dwts. Au. E. I. S.

**Copper belt at Mount Perry**. J. T. AMOS. *Queensland Govt. Mining J.* 30, 110-11 (1929).—Unlimited ore is available. E. I. S.

**Amamoor manganese deposits**. C. C. MORTON. *Queensland Govt. Mining J.* 30, 96-8 (1929).—Production is about 1600 tons from two open cuts. The ore is dense psilomelane with 50-54% Mn, and meets requirements of the steel industry as to silica and P contents. E. I. S.

**Microscopic study of complex ores from Colquijirca, Peru, containing copper and silver**. J. ORCEL AND GIL RIVERA PLAZA. *Compt. rend.* 188, 181-3 (1929).—The following types are distinguished: (1) Cu-Ag ores characterized by the constant presence of native Ag or of an argentiferous mineral such as stromeyerite or pyrrargyrite; (2) Cu and Pb-Cu ores including chalcopryrite, bornite, tetrahedrite, sometimes with galena; these are also argentiferous, but much less so than (1); (3) Pb-Zn ores accessory to (2) and with variable % of Ag. The minerals present in each type are enumerated. The gang of all these minerals is formed principally of barite, white colloidal Ag and siderite. The microscopic examn. showed that there exist 2 types of minerals of different origin: (1) deep-seated, including chalcopryrite, sphalerite, galena, pyrite, enargite, tetrahedrite, bornite; (2) minerals of the zone of cementation formed by means of metasomatic replacement of part of the above and characterized by the presence of native Ag and stromeyerite. A. J. MONACK

**Geology of the ball clays of South Devon**. A. SCORR. *Trans. Ceram. Soc. (England)* 28, 53-61 (1929). H. F. KRIEGE

**Rock crystal and diamond pipes in Brazil**. R. R. WALLS. *Geol. Mag.* 46, 111-6

(1929).—Near Diamantina, Minas Geraes, the occurrence of rock crystal in metamorphosed quartzite, where the action of heated vapors was indicated, led to the discovery of potentially diamondiferous pipes. The diamond mines of Sopa and Boa Vista, in the weathered portion of 2 of these pipes, had been worked as ordinary alluvial deposits. A. M. BRANT

The quartz-basalt of Taradake, Japan. T. OGURA. *Geol. Mag.* 46, 68-71(1929).—The formation of this rock may be explained by magmatic differentiation. The phenocrysts of quartz and oligoclase in the upper acid magma (dacite) partly sank down into the lower basic zone and became ingredients of the basalt. The quartz phenocrysts are partly altered to tridymite. A. M. BRANT

An unusual college monument. C. A. BONINE. *Am. Mineral.* 14, 200(1929).—A monument known as the Polyolith containing every known building stone in Pa. stands on the campus of the State College. It indicates how the various stones have withstood weathering during 33 years. A. M. BRANT

The radioactive constituents of hokutolites and other minerals from Japan. JUN YOSHIMURA. *Bull. Inst. Phys. Chem. Research (Tokyo)* 8, 223-7(1929); *Abstract Sect. 2*, 29-30.—The Ra and Th contents of hokutolites, allanite and xenotime from Japan were detd. For Ra Soddy's emanation electroscope was used, and for Th the const. current method. The results are:

Mineral	Locality	Ra (%)	U (U <sub>3</sub> O <sub>8</sub> ) (%)	Th (ThO <sub>2</sub> ) (%)
Hokutolite	Hot spring of Hokuto, Taiwan	$1.73 \times 10^{-7}$	...	0.02
Hokutolite	Hot spring of Shibukuro, Akita P.	$1.22 \times 10^{-7}$		0.01
Allanite	Shirakawa near Kyoto	$4.87 \times 10^{-9}$	0.017	1.05
Xenotime	Ishikawa, Fukushima P.	$6.98 \times 10^{-7}$	2.42	

In the above table, the U content was calcd. from the amt. of Ra, the recognized equil. ratio being applied. The Ra and Th contents of both hokutolites are of the same order of magnitude. The radioactivity of this substance is mainly ascribed to Ra and its disintegration products, the effect due to the Th series being slight, since the quantity of Th present is relatively very small. With the xenotime, the sample used contained assocd. zircon; hence the decompn. was effected by boiling with concd. H<sub>2</sub>SO<sub>4</sub>, and the activity of the evolved emanation was measured; the amt. of Ra shown in the table may, however, include a little from the zircon. Also in *Sci. Papers Inst. Phys. Chem. Research, Suppl.* 10, No. 10, 47-52(1929). G. CALINGAERT

The moon and radioactivity. V. S. FORBES. *Geol. Mag.* 46, 57-65(1929).—On the assumption that the moon was originally derived from the outer layers of the earth, the surface features of the moon can be ascribed to a period of cataclysmic vulcanicity, marked by violent eruptions, releasing the pent-up heat derived from the radioactive constituents. A. M. BRANT

## 9—METALLURGY AND METALLOGRAPHY

\* D. J. DEMOREST AND R. H. ABORN

The dressing of argillaceous ores. WILHELM WITTE. *Arch. Eisenhüttenw.* 2, 607-12(1929).—The dressing of the limonite ores in Vogelsberg with the Excelsior machine is described; this device works with a sand bath and thick slimes. J. B.

Consumption of reagents used in flotation, 1927. A. M. GAUDIN. *Bur. of Mines, Repts. of Investigations* No. 2931, 17 pp.; *Eng. Mining J.* 127, 999-1003(1929).—An investigation covering trends in the choice of reagents and the extent to which new reagents are displacing less suitable older ones. The general trend has led to the

more extensive use of chem. collector, the more widespread and judicious use of alk. circuits and greatly increased consumption of depressing reagents. W. H. BOYNTON.

**Mechanical preparation of minerals.** VICTOR CHARRIN. *Science & ind.* 1929, 238-40; cf. C. A. 23, 2512.—C. discusses *enrichment by flotation*. Various types of app. are shown and schematic diagrams are used to explain industrial installations.

A. J. MONACK

**Differential grinding applied to tailing retreatment.** LEON M. BANKS AND GEORGE A. JOHNSON. *Am. Inst. Mining Met. Eng., Tech. Pub.* No. 217, Preprint, 11 pp. (1929).—A difference was noted in the type of tailings from upper-level and lower-level ore, the latter contg. hard lime chats bearing blende and the former soft, porous, cellular lime chats contg. varying amts. of blende. The tailings were a mixt. of lime and flint with some shale, most of the blende being attached to the dolomite. Comparison of ball mill and roll-crusher grinding favors the latter, due in the first instance to a marked enrichment of the fines and an impoverishment in the larger sizes, that is not obtained in the roll-crushing. A preliminary concn. can be effected by a quick ball-mill grind, followed by a screening of the discharge. This permits a discard of about 50% by wt. Lab. results were duplicated under operating conditions. W. H. B.

**Influence of varying proportions of ore and slag on the yield of the Siemens-Martin furnaces.** G. BULLÉ. *Met. ital.* 20, 517-32 (1928); cf. C. A. 22, 2131.—A large no. of mixes were made with varying proportions of ore and slag, as well as with ores of different compns., and the yield and compn. of the resulting steels noted. No general conclusions are drawn. A. W. CONTIERI

**The influence of the addition of lime on metal slag systems. A contribution of the question of slag reactions.** E. DIEPSCHLAG AND H. FLIEGENSCHMIDT. *Zentr. Hutten- u. Walzwerke* 31, 551-6, 567-72, 587-90 (1927); *Chem. Zentr.* 1928, I, 112-13. Heating pure  $\text{CaCO}_3$  above the dissocn. point for  $\text{CO}_2$  results in a shrinkage in vol. and the formation of a lattice of crystals. Impurities cause liquefaction and the cementing of the mass. The most shrinkage occurs between  $1200^\circ$  and  $1400^\circ$ .  $\text{CaF}_2$  in quantities to 3% causes a marked lowering of the softening point. The study of the reaction between  $\text{CaO}$  and  $\text{SiO}_2$  confirmed the results of other investigators. Heating  $\text{FeO} \cdot \text{SiO}_2$  with  $\text{CaO}$  for 1 hr. at  $1200^\circ$  displaces  $\text{FeO}$ . The reaction takes place quickly at  $900^\circ$  if  $\text{CaF}_2$  is added because of the increase in liquid phase. FRANCIS P. GRIFFITHS

**Blast roasting at Cerro de Pasco.** GLENN A. KEEP. *Am. Inst. Mining Met. Eng., Tech. Pub.* No. 209, 12 pp. (1929).—Properly crushed ore is mixed with salt, water and sufficient coal or sulfide ore to produce a roasting temp. of  $650^\circ$  to  $700^\circ$ . Addition of correct amt. of moisture is important in yielding a porous mix which will allow passage of air through the charge. When the charge is roasted through on top, air is shut off, the roaster grates are started and the charge is dropped to 22-24 ins. After the red hot calcine is spread evenly over the grate area, a full charge of mix is drawn into the roaster from the overhead bin. The new charge is leveled on top and air pressure turned back on the roaster. The new charge is ignited from the hot bottom layer and proceeds to roast through to the top, completing the cycle. Nine to 10 cycles a day are made. Successful roaster operation depends on good mixing

H. C. PARISH

**Function of steel-plant metallurgy.** R. E. SHERLOCK. *Iron Age* 123, 1639-41 (1929).

**Foundry sands and their applications.** G. C. CASTLE. *Iron & Steel Ind. & Brit. Foundryman* 2, 265-7, 286 (1929).

**Refractory materials for the foundry.** ALFRED B. SEARLE. *Iron & Steel Ind. & Brit. Foundryman* 2, 269-73 (1929).

**The mixing end selection of foundry irons.** J. E. HURST. *Iron & Steel Ind. & Brit. Foundryman* 2, 261-3 (1929).—The phys. properties and chem. compn. of pig Fe are considered in the proper selection of foundry Fe.

**Using scrap in steel, gray iron and malleable mixtures.** E. K. SMITH AND F. B. RIGGAN. *Foundry* 57, 514-8 (1929).—See C. A. 23, 2131.

**The casting of steel ingots.** FRANZ PACHER. *Stahl u. Eisen* 49, 627-45 (1929). The most favorable casting and solidifying conditions are reviewed. The effects of the temp., chem. compn., size, form and cooling of the ingots are discussed. The defects caused by faulty thermal, mechanical and metallurgical treatments are outlined. A new pressure method, similar to the method of Harmet, is given. According to this method, which prevents segregation and piping, a piston subdivided like a telescope is pressed upward against the liquid part of the ingot. J. A. SZILARD

**The fragility of homogeneous iron.** G. SIROVICH. *Met. ital.* 21, 1-17 (1929).—A large no. of photomicrographs were made of various fractures in samples of "homo-

geneous" iron, *i. e.*, low-C steel. S. feels that Italy is not justified in using this type of steel so extensively, as it has lower strength than the higher-C steels, and more of it is required, which is uneconomical to a country so poor in natural resources. The higher-C steels, although somewhat higher priced, more than compensate for this by the reduced amt. required.

**Experiments on the working of galena-wulfenite concentrates.** W. HERTEL. *Metall u. Erz* 26, 115-8 (1929).—Wet and dry methods given in the literature for working the pure Mo ore prove unsatisfactory when used on the galena-wulfenite concentrate. By passing gaseous HCl over the finely divided ore, the Pb and Mo therein may successfully be sepd. Expt. shows that at 390°, heating for 1.75-2.0 hrs., all the Mo above 0.4% is sublimed off. Under these conditions practically all of the Pb is converted into PbCl<sub>2</sub>.

**Cyanide regeneration or recovery as practiced by the Compania Beneficiadora de Pachuca, Mexico.** C. W. LAWR. *Am. Inst. Mining Met. Eng., Tech. Pub. No.* 208, 37 pp. (1929).

**Construction of a (gas) metal-melting furnace.** E. SCHUMACHER. *Gas u. Wasserschiff* 72, 369-75 (1929).—Details of construction of a gas-fired furnace capable of melting up to 50 kg. of brass or bronze in 1½ to 2½ hours, the former value being obtained when the air for combustion is preheated by the products of combustion. R. W. R.

**History of the blast furnace in Steiermark (Austria).** RUDOLF SCHAUR. *Stahl u. Eisen* 49, 489-98 (1929).

**The charging equipment of blast furnaces and its effect on their operation.** HUBERT HOFF. *Stahl u. Eisen* 49, 613-27 (1929).—Construction details are given, with examples from well-known plants.

**Use of blast-furnace and coke-oven gas in open-hearth furnaces.** FRANK R. LEAHY. *Iron Age* 123, 1486-8 (1929); *Blast Furnace and Steel Plant* 17, 857-61 (1929).—The advisability of using a mixed gas composed of blast-furnace and coke-oven gas in open-hearth furnaces under certain economical conditions is pointed out. The construction of the open-hearth furnace, especially the checkers, should be altered for the efficient use of the mixed gas. Figures are given for flame temp. which show the benefit of preheating the blast-furnace gas.

**Large open-hearth furnaces.** F. A. KING. *Blast Furnace & Steel Plant* 17, 850-1 (1929); cf. *C. A.* 23, 2399.—Their advantages are outlined.

**The development of copper mat concentration in the shaft furnace, the reverberatory furnace and the converter.** OTTO BARTH. *Metall u. Erz* 26, 66-9 (1929).—The development of these furnaces in Mansfeld is traced.

**High-purity magnesium produced by sublimation.** H. F. BAKKEN. *Chem. Met. Eng.* 36, 345-7 (1929).—Crude, 90-95% Mg can be refined to a 99.99% Mg by distn. under low pressure. (U. S. Pat. 1,594,345; *C. A.* 20, 3215). A still permits continuous charge and discharge by means of a vacuum lock and a vacuum chamber discharge. The product is obtained as ingots without oxidation.

**South African platinum.** J. SCHLENZIG. *Metallbörse* 19, 1153-4 (1929).—Pt was discovered in the Waterberg district in 1923. Deposits have been found elsewhere; in norite (a metamorphosed volcanic rock) they run about 6 dwt./ton, in sulfide-bearing norite ores contg. 3.5-11.0 dwt./ton, and in the Merensky Reef with a content of 3 dwt. and less/ton. Sulfide-norite ores are concd. by flotation, with eucalyptus oil, paraffin and xanthate, with a recovery of 85-90% of the Pt. With oxidized ores the concentrates are roasted and leached by the so-called German process. For pure sulfide concentrates a chlorination process has proved successful. For horton-olite-dunite ore, with its large particles of metallic Pt, a concentrate is obtained and then amalgamated with Hg, CuSO<sub>4</sub>, H<sub>2</sub>SO<sub>4</sub> and Zn-amalgam.

**Rare metals.** Cobalt, molybdenum, nickel, tantalum, titanium, tungsten, radium, uranium and vanadium in 1927. FRANK L. HESS. *Bur. Mines, Mineral Resources of the U. S.* 1927, Pt. I, 393-453 (Preprint No. 17, published May 1, 1929).

**Secondary metals in 1927.** J. P. DUNLOP. *Bur. Mines, Mineral Resources of the U. S.* 1927, Pt. I, 373-92 (Preprint No. 16, published April 4, 1929).

**Gold, silver, copper, lead and zinc in New Mexico.** CHAS. W. HENDERSON. *Bur. Mines, Mineral Resources of the U. S.* 1927, Pt. I, 455-79 (Preprint No. 18, published May 17, 1929).

**The appearance, prevention and repair of different kinds of flaws in welded and hard-soldered objects.** H. REININGER. *Metallbörse* 19, 482-4, 538-40 (1929).—Flaws or imperfections in joints are divided into 4 classes: (1) those due to shrinkage during cooling, (2) flaws that appear after cooling, due to internal stresses, (3) those due to inclusions of oxides, etc., and (4) flaws due to imperfect union of metal to metal, prob-

ably because of temp. improperly regulated at time joint was made. Mech. processes for preventing and curing such troubles are given. Fluxes ought to melt about 30° lower than the metal used as a solder. W. C. EBAUGH

Causes of corrosion of magnetite electrodes. FRIEDR. VOGEL. *Metallbörse* 19, 761(1929).—Insol. magnetite anodes are made usually from the residues from pyrite burners; the  $\text{Fe}_2\text{O}_3$  so formed is melted in an elec. furnace, poured into molds and tempered. Chem. and microscopic investigations showed that (1)  $\text{SiO}_2$  in  $\text{Fe}_2\text{O}_3$  used should not exceed 3%, and (2) the melted  $\text{Fe}_2\text{O}_3$  should be poured into hot molds and tempered slowly. In faulty anodes it was found that Fe silicates (slags) had segregated, thus forming places of attack. W. C. EBAUGH

Impurities in acetylene. Effects of phosphine on welding. G. LE GRIS. *Welding J.* 24, 345-7(1927); *J. Inst. Metals* 39, 644.—In an air-acetylene flame the phosphine is not completely burnt and some escapes in the free state. Such flames readily give up P to both Cu and Fe, forming phosphide eutectics. In an oxy-acetylene flame, on the other hand, all the phosphine is burnt, and a Cu wire, placed well away from the high-temp. portion of the flame, does not absorb much P. In actual welding practice, however, where the hot part of the flame is used, the phosphine may not be entirely burnt, and P absorption occurs. Expts. with Cu and Fe are described, and the need for purification of the acetylene is emphasized. H. L. D.

Special metals required for extreme temperatures and pressures. A. E. WHITE and C. L. CLARK. *Power* 69, 898-9(1929).—Charts show the phys. properties of various steels up to 1300° F. D. B. DILL

Hardening of metal alloys. W. GUERTLER. *Metallwirtschaft* 8, 510-5(1929).—G. discusses the mechanism of the constitutional changes produced in alloys by heat treatment and mech. working, with particular reference to the analysis of phase diagrams. H. STOERTZ

The technology of the metallographic examination of very hard alloys. KARI. SCHRÖTER. *Z. Metallkunde* 20, 31-3(1928); *J. Inst. Metals* 39, 534-5.—Prepn. for microscopic examn. of samples of so-called hard metals which chiefly contain W carbide in addn. to Ti, Fe, Ce and Cr, is described in detail. Aq. alk. solns. of  $\text{K}_3\text{Fe}(\text{CN})_6$  and mixts. of concd.  $\text{HNO}_3$  and concd. HF were found to be suitable etching reagents. Photomicrographs are given of various cutting metals known as Tizit, Volumit, Lohmanit, Thoran, Miramant, Arboga and Widia. H. L. D.

Torsional modulus of carbon steel, phosphor bronze, brass and Monel metal. W. P. WOOD. *Trans. Am. Soc. Steel Treating* 15, 971-81(1929).—The deflection method being used, modulus detns. were made upon 3 types of steel, P bronze, brass and Monel metal as used in spring construction. In steel, quality and manuf. affect the torsional modulus more than chem. compn. and heat treatment. A decrease in Zn causes an increase with brass. Variations in any of the factors appearing in the ordinary deflection formula for helical springs affects the torsional modulus only slightly. W. A. MUDGE

Influence of the elements upon the polymorphism of iron. FRANZ WEVER. *Arch. Eisenhüttenw.* 2, 739-48(1929).—After a discussion of the classic theories of the structure of mixed crystals and metallic compds., the polymorphism of Fe and the influence of other elements upon it are studied. A relation is demonstrated between the influence of an element upon the crystal structure of Fe and the at. radius of that element or its position in the periodic system. The same relation probably also applies to the structural properties of homogeneous mixed crystal series. H. STOERTZ

Single crystals of iron. H. GRIES and H. ESSER. *Arch. Eisenhüttenw.* 2, 749-61(1929).—A study of methods for the production of Fe single crystals. The influence of initial grain size upon the degree of deformation required to produce recrystn. is considerable. Thus with 250 grains per sq. mm., the degree of deformation required is only 2.85%, while with 22 grains per sq. mm., it is 9.0%. The uniformity of the deformation, crystallite orientation with respect to the force producing deformation, and O content all affect the beginning of recrystn. Pressure figures and reflection phenomena are used in detg. crystallite orientation. Hardness varies on the different crystal faces, being lowest on the cubic face and highest upon the rhombic dodecahedral face. Increased O content produces increased hardness. With 0.03% O, the Brinell no. was 70.2; with 0.141% O, the Brinell no. was 79.6. H. STOERTZ

The change of specific gravity of cold-worked iron and steel by tempering. KANZI TAMARU. *Bull. Inst. Phys. Chem. Research (Tokyo)* 8, 187-96(1929); *Abstract sect. 2*, 25-6.—The temp. of strain-release for Fe and steel was detd. from change of density and was found to be 400° for all specimens treated. Armco Fe showed a max. at 150° and a min. at 400°. The values of the max. and the min. decreased with the C content

of the steel, disappearing finally at 0.2% C. When the strained specimen is tempered at a low temp., a min. increase in grain size takes place, and hence, the sp. gr. increases to yield a max. If the tempering temp. is raised still higher, the interior of the grain seps. into a series of thin layers and increases the total surface of the grain, thus yielding a min. d.

G. CALINGAERT

Effects of nickel and chromium on cast iron. I. D. HANSON. *Metallurgist* (Suppl. to *Engineer* 147, Mar. 29) 38-40(1929).—As the % of Ni is increased to 20, Brinell hardness passes through a max. at 2% Ni and a min. at 3% Ni. Then there is a slight rise followed by a continuous decline. Micro-structures are illustrated and explain the shape of the curve. The first effect of Si is similar but there is no second max. Increasing concn. of Si gives graphite and a soft weak matrix. II. *Ibid* (Suppl. to *Engineer* 147, Apr. 26) 56-60.—The effects of Ni and Si together can be explained on the assumption that each element exerts its characteristic influence and that the final result is essentially the sum of the 2 effects. With good quality gray iron, Si decomposes free carbide, eliminates chilling, softens the matrix; Ni decomposes free carbide but hardens the matrix; Cr stabilizes free carbide, increases chilling and hardens the matrix.

D. B. DILL

The influence of nickel on combined carbon in gray iron. J. R. HOUSTON. *Trans. Am. Soc. Steel Treating* 15, 145-53(1929).—Ni is a "pearlite builder" in gray Fe and permits a control of the amt. and structural form of combined C to give density to heavy sections and machinability to light sections.

W. A. MUDGE

Graphitization in the presence of nickel. H. A. SCHWARTZ. *Trans. Am. Soc. Steel Treating* 15, 957-66(1929); cf. *C. A.* 23, 2136.—Si is inoperative as an accelerator in the presence of Ni. No explanation is offered for the different behavior of Si and Ni as accelerators.

W. A. MUDGE

The thermal conductivities of gray cast irons. J. W. DONALDSON. *Proc. Inst. Mech. Eng.* (London) 1928, 953-83.—App used for detg. the thermal conductivities was based on the guard-ring method. Heat is applied at one end of the test bar and its enclosing guard ring or tube while sep. calorimeters remove the heat from the other end of the test bar and guard ring. Three thermocouples 4 ins. apart give temp. differences along the test bar. Series of tests were made on 4 plain irons and several alloy irons. Increasing Si reduced cond. Within the present P variation (0.17-0.81%) its effect on thermal cond. is small. Cr and W increase cond. while Ni and V decrease it. Heat treatment at 550° at first increases the thermal cond. because pearlite decomposes to form ferrite and graphite, after which the oxidation of iron in the vicinity of the graphite flakes causes a slight decrease. Free ferrite appears to be a much better conductor of heat than eutectoid pearlite.

A. W. HOLMES

Deoxidation of steel with silicon. C. H. HERTY, JR., AND G. R. FITTERER. *Trans. Am. Soc. Steel Treating* 15, 569-84(1929); cf. *C. A.* 23, 801.—Complete deoxidation of steel is impossible unless the oxide formed is infusible and insol. at steel-making temps. Silicates high in Fe or Mn are more readily eliminated from the bath than high silica particles because of their lower m. p.

W. A. MUDGE

The manufacture of acid open-hearth steel for forging ingots. H. P. RASSBACH. *Trans. Am. Soc. Steel Treating* 15, 289-302(1929).—A description of modern open-hearth furnacing with particular reference to the casting of a 210 ton ingot.

W. A. M.

Oxygen in iron and steel. II. Influence of oxygen upon the structure and a few properties of various structural steels. P. OBERHOFFER, H. HOCHSTEIN AND W. HESSENBRUCH. *Arch. Eisenhüttenw.* 2, 725-38(1929).—A comparison of O-rich and O-poor Ni, Ni-Cr, Cr-W, W, Cr, Mo and V steels, with respect to behavior in casting and in forging, and effect upon red shortness, crystal structure, hardness, etc. O content ranged from 0.005% to 0.062%. Steels high in O show a coarser structure than O-poor steels, and thereby exhibit a greater tendency to an internal cryst. structure and a complicated arrangement of ferrite and perlite. In the investigation of red shortness, Jansen's formula (O-Mn 16/25) is found to hold for these steels. In the process of cementation, O-rich steels show a small depth of cementation zones and a small irregular grain in the hypereutectoid zone. V steels show abnormal structure throughout. The range of hardness of O-poor steels is greater than for O-rich steels. The latter tends strongly to overheating. In O-poor steels, the decrease in hardness takes place in a small temp. range, while O-poor steels tend to scale fracture. Conclusive results were not obtained as to the effect of O upon the production of brittleness.

H. STOERTZ

Hair-line cracks upon the surface of (steel) plates. ERICH A. MATEJKA. *Arch. Eisenhüttenw.* 2, 681-705(1929).—The chief cause seems to lie in the great difference in temp. between the inside and surface of the material to be rolled. It is above all

essential that the rough block as well as the block for preliminary rolling be uniformly preheated, any appreciable temp. difference between the surface and center of the piece being avoided. Finally, it is important that the proper relation between rolling pressure and temp. be chosen to avoid overloading the surface particles of the metal.

Steels are now available for high pressures and temperatures. H. STOERTZ AND J. J. KANTER. *Power* 69, 904-5(1929).—High-temp. strengths of alloy and cast steels are shown graphically up to 1200° F.

Depth and character of case induced by mixtures of ferro alloys with carburizing compounds. E. G. MAHIN AND R. C. SPENCER. *Trans. Am. Soc. Steel Treating* 15, 117-41(1929).—A deep case without a zone of free cementite has been produced by mixing 20% Fe-Si with an ordinary carburizer and using higher temps. The time of the operation is shortened.

Solubility of carbon in normal and abnormal steels. OSCAR H. HARDER AND WILLARD S. JOHNSON. *Trans. Am. Soc. Steel Treating* 15, 49-62(1929).—Pptn. takes place at higher temps. in abnormal steels with similar C contents. The amt. of C taken up by normal and abnormal steels becomes essentially the same as the carburizing temp. increases. Photomicrographs show typical structures.

Magnetic investigations of carbon steels. CLIFFORD C. QUELL. *Trans. Am. Soc. Steel Treating* 15, 630-51(1929).—A drop in magnetism occurs from 150 to 200° in steels contg. Fe<sub>3</sub>C. In steels contg. only martensite decreased magnetism occurs at 300°.

Steel failures in aircraft. F. T. SISCO. *Trans. Am. Soc. Steel Treating* 15, 589-624(1929).—A discussion of failures in steel aircraft parts which have been investigated at Wright Field.

Surface cooling of steels in quenching. H. J. FRENCH, G. S. COOK AND T. E. HAMILL. *Trans. Am. Soc. Steel Treating* 15, 217-84(1929).—The characteristics of the cooling curves of 1/4-1 1/4 in. diam. steel spheres in H<sub>2</sub>O, NaOH solns., oils and air and the effects of some of the variables encountered in com. heat treatment. Center and surface cooling curves obtained for pressure spray quenching with H<sub>2</sub>O are correlated with tensile and impact properties.

Service annealing of sling and crane chains. WM. J. MERTEN. *Trans. Am. Soc. Steel Treating* 15, 193-209(1929).—Heat treatments are given for original and service annealing. An initial, high temp. treatment above AC<sub>3</sub> for grain refinement is imperative.

The effect of furnace atmospheres on steel. R. G. GUTHRIE. *Trans. Am. Soc. Steel Treating* 15, 96-105(1929).—Scaling or oxidation with O<sub>2</sub> does not cause decarburization at 1500° F. CO<sub>2</sub> alone both decarburizes and oxidizes.

Austenitic decomposition and length changes in steel. EDGAR C. BAIN AND WILLIS S. N. WARING. *Trans. Am. Soc. Steel Treating* 15, 69-90(1929); cf. *C A* 23, 585.—A preliminary study with an oil-hardening die steel and a stainless steel to show that the efficiency of quenching mediums and knowledge of the nature of the steel may be obtained by measuring length changes during quenching.

Studies on martensite. J. ORLAND. *Anal. usoc. ing.* (Madrid) 8, 28-39, 141-53(1929).—Martensite is not a solid soln. of  $\gamma$ -iron and C. It is always present in needle-like form and in 2 distinct phases distinguishable by etching with nitric or picric acid. insol. white needles being allied with austenite grains.

The martensite system. K. GEBHARD, H. HANEMANN AND A. SCHRADER. *Arch. Eisenhüttew.* 2, 763-71(1929).—A thermal and photomicrographic investigation of martensite, using electrolytic Fe and steels with C content ranging from 0.06 to 1.75%. The heterogeneity of martensite is established, as well as the existence of a second metastable system of Fe-C alloys. Photomicrographs and a phase diagram of the martensite system are included. In the metastable martensite equil. only  $\epsilon$ -Fe occurs up to about 0.1% C. From 0.1 to 0.37% C, martensite consists of  $\epsilon$ -Fe and *heynite* ( $\delta$ -phase), while between 0.37 and 0.9% C, *heynite* and *hardenite* ( $\eta$ -phase) are the constituents of martensite. With more than 0.9% C, a quenched steel contains *hardenite* and *austenite*, the austenite increasing as C increases. If the steel contains more than 1.1% C, the  $\eta$ -phase crystallizes from the  $\gamma$ -Fe immediately. If the equil. is not completely established, hardened steel contains austenite even with less than 0.9% C, and *heynite* even with more than 0.9% C.

Further observations on the microstructure of martensite. FRANCIS F. LUCAS. *Trans. Am. Soc. Steel Treating* 15, 339-64(1929).—A further contribution to the microstructure of martensite. Excellent photomicrographs at high magnification show representative structures in quenched and tempered conditions. A martensitic needle

is a decompn. along the octahedral crystallographic planes of austenite, has a mottled granular appearance and is confined to an area of uniformly oriented austenite. It is an aggregate and not a solid soln. and indicates a decompn. of the austenite, probably to  $\alpha$  Fe and  $\text{Fe}_3\text{C}$  highly dispersed.

Comparative tests of tool steels. L. PERSOZ. *Aciers spéciaux* 4, 121-3 (1929).—W. A. MUDGE  
P. presents a fairly complete review of the subject. A. J. MONACK

A study of the constitution of high-manganese steels. V. N. KRIVOBOK. *Trans. Am. Soc. Steel Treating* 15, 893-928 (1929).—A study of the constituents of austenitic Mn steel (Hadfield) under different conditions of treatment. Austenite is decompd. by cold working followed by heating to suitable temps. W. A. MUDGE

High-chromium steels. OWEN K. PARMITER. *Trans. Am. Soc. Steel Treating* 15, 796-816 (1929).—A general discussion of compn., heat treatment, phys. properties and resistance to corrosion of low-C stainless steel types and several high-C-Cr die types. W. A. MUDGE

An investigation of the physical properties of certain chromium-aluminum steels. FRANK B. LOUNSBERRY AND WALTER R. BREELER. *Trans. Am. Soc. Steel Treating* 15, 733-62 (1929).—Alloys contg. 2-6% Al, 7-13% Cr and 1% Si plus C were investigated. Al effectively stabilizes the  $\alpha$ -Fe phase and, when in combination with Cr, greatly increases the resistance of the metal to oxidation at elevated temps. W. A. MUDGE

Surface hardening of special steels with ammonia gas. RAYMOND H. HOBROCK. *Trans. Am. Soc. Steel Treating* 15, 543-57 (1929). See C. A. 23, 1607. W. A. M.

Cutting qualities of an alloy steel as influenced by its heat treatment. O. W. BOSTON AND M. N. LANDIS. *Trans. Am. Soc. Steel Treating* 15, 451-67 (1929).—The S. A. E. 6140 steel cuts best when spheroidizing is greatest. The drill torque increases as machining qualities are improved. There is no relation of drill thrust to machining qualities. W. A. MUDGE

A new method for heat treating high-speed steel. HORACE C. KNEER. *Trans. Am. Soc. Steel Treating* 15, 429-45 (1929).—Features of the method describe induction heating of salt baths, prolonged container life and a salt bath, which does not give off fumes or attack the tools. W. A. MUDGE

High-carbon, high-chromium steels. J. P. GILL. *Trans. Am. Soc. Steel Treating* 15, 387-420 (1929).—A comparison of the heat treatment, phys. properties and microstructures of 6 high-C, high-Cr die steels. W. A. MUDGE

Stainless iron and its application to the manufacture and transportation of nitric acid. WALTER M. MITCHELL. *Trans. Am. Soc. Steel Treating* 15, 303-26 (1929); cf. C. A. 23, 2919.—A discussion of the Cr and Cr-Ni stainless steels with special reference to resistance to corrosion in the  $\text{NH}_3$  oxidation process for  $\text{HNO}_3$ . W. A. M.

Chromium-copper steels as possible corrosion-resisting ferrous alloys. B. D. SAKLATWALLA AND ALBERT W. DEMMLER. *Trans. Am. Soc. Steel Treating* 15, 36-48 (1929).—Phys. properties and resistance to corrosion are given for Cr-Cu steels contg. com. and practical ranges of the 2 elements to show possibilities of high strength with fair corrosion resistance at a reasonable cost. W. A. M.

The stress-strain diagrams of a heat-treated nickel-chrome steel. I. Compression tests. ANDREW ROBERTSON AND A. J. NEWPORT. *Metallurgist* (Suppl. to *Engineer* 147, Feb. 22) 23-6 (1929).—Tests were made on tubes  $1\frac{1}{4}$  in. in diam., 18 gage, contg. C 0.25, Ni 4.1 and Cr 1.25%. If tempered at 700-750° and cooled in air, the elastic limit is low. If hardened at 800-900° and tempered at 400°, it has an elastic limit of 60 tons per sq. in. and is toolable. There is evidence of definite "mass" effect as slow cooling and air cooling have unlike results. II. *Ibid* (Suppl. to *Engineer* 147, Mar. 29) 35-6.—Tension tests were carried out on steel bars of the same material. Stress-strain diagrams are similar to those obtained by compression tests. D. B. D

Methods of approximating certain physical characteristics of nitrified steel cases. G. M. HATON. *Trans. Am. Soc. Steel Treating* 15, 1-24 (1929).—The Vickers diamond indenter hardness tester offers a practical method for inspecting nitrified steel products. W. A. MUDGE

Properties of carburized tungsten. B. T. BARNES. *J. Phys. Chem.* 33, 688-91 (1929).—A study is made of the spectral and total emissivity and m. p. of  $\text{W}_2\text{C}$ . The spectral emissivity measurements were made on tubular, pressed W filaments, carburized and uncarburized, a pyrometer being used. The emissivity measurements of surface carburized to  $\text{W}_2\text{C}$  showed an increase of 0.03 at any given temp. Total emissivity measurements were made on 10-mil. W filaments before and after carburizing; these results are shown graphically. As with spectral emissivity there is an increase in total radiation with increased carburization. The carbide layer was usually of uni-

form thickness, independent of crystal boundaries; decarburization is less regular. A method for detg. the m. p. is summarized.

Present status of tungsten carbide as cutting material. F. C. SPENCER. *Am. Mach.* 70, 865-7; *Abrasive Ind.* 10, No. 7, 23-4 (1929).—A.S.M.E. committee rept.

Latest results from tungsten carbide tools. W. P. EDDY, JR. AND H. J. LONG. *Machy.* (N. Y.), 3, 783-4; *Iron Age* 123, 1414-6 (1929).

Nickel-chromium alloys in electrical resistance heating. W. R. BARCLAY AND G. E. M. STONE. *Elec. Times* 73, 82-4 (1928); *J. Inst. Metals* 39, 624-5.—Of the alloys so far developed the Ni 80, Cr 20% binary alloy for use at temp. up to 1100° (wire temp.), and the ternary alloy contg. Ni 60/65, Cr 12/15%, and remainder Fe for temps. up to 850° (wire temp.), are among the most valuable. The alloys are worked hot in the early stages, but the later stages of the manuf. of tapes and wire are carried out cold.

Solubility of cupric sulfide in cuprous sulfide at high temperatures. I. G. VUKOV. *Metall u. Erz* 26, 137-41 (1929).—Electrolytic Cu and pure S are heated together in various proportions in a vacuum elec. furnace at 1140-1180°. Increasing S content lowers the f. p. of the mixt. Free S is not found until the S content exceeds 22.4%, corresponding to 16% CuS. Microscopic examn. of the melts shows that up to 16% CuS, the sulfides form solid solns. with one another.

Contribution to the metallurgical study of antique bronzes. BUTESCU. *Ann. Mines* 13, 177-92 (1928); *J. Inst. Metals* 39, 681.—Particulars of the analytical and metallographical examn. of some antique bronze swords, axes, daggers, etc., found in Rumania. The majority of these contained from 11 to 13% Sn, but 1 or 2 contained considerably less. Zn was absent, and the Pb content was usually very small, and never more than 1%. They showed the dendritic structure characteristic of cast metals, but it is not stated whether evidence of working or deformation after casting was found. The objects probably belong to the period 1400-1100 B. C.

Study of nickel-copper alloys. ALEXANDRE KRUPKOWSKI. *Rev. métal.* 26, 131-53, 193-208 (1929); cf. *C. A.* 23, 1544.—The Ni-Cu alloys used were carefully homogenized by annealing for several days at 800-900°. The measurements were made with very accurate instruments and by the most sensitive methods. The conclusions follow: (1) The line of magnetic transformation is a straight line which cuts the horizontal corresponding to *abs.* 0° extrapolated from measurements down to -250° at a compn. of 41.5% Ni by wt. (2) The crit. pts. corresponding to the transformation  $Cu_{\alpha} \rightarrow Cu_{\beta}$  for alloys ranging from 2.1 to 38.8% Ni were detd. by low-temp. elec. resistance methods. (3) From the shape of the  $\alpha$  (elec. resistance temp. coeff.) curves, it was detd. that immediately after the transformation  $Cu_{\alpha} \rightarrow Cu_{\beta}$ ,  $Ni_{\alpha} \rightarrow Ni_{\beta}$  the value of  $\alpha$  decreases and passes through a min. This favors the formation of alloys having a const.  $\alpha$  coeff. over a certain temp. range, *e. g.*, *constantan*. (4) From the shape of the curves of the transformation  $Cu_{\alpha} \rightarrow Cu_{\beta}$  and  $Ni_{\alpha} \rightarrow Ni_{\beta}$ , Ni-Cu alloys have been divided into 2 classes in accordance with Tamman's theory; in the 1st class of alloys, contg. 0-41.5% Ni, Cu acts as solvent, and in the 2nd class, contg. 41.5-100% Ni, Ni acts as solvent. The 1st class of alloys are not ferro-magnetic at any temp.; the 2nd class can be either ferro- or para-magnetic according to the temp. (5) Micrographic examn. showed the existence of solid solns. in all Cu-Ni alloys, there being no modification in structure either in passing from the para- to the ferro-magnetic state or in passing from alloys in which Cu is the solvent to those in which Ni is the solvent. (6) Careful examn. of the curves of elec. resistance, of temp. coeff. of elec. resistance, of thermo-elec. force and its variation with temp., of expansion coeff., of hardness coeff., of coeff. of soln. *e. m. f.* taken in connection with the results of metallographic examn. contradicts the existence of a compd. CuNi.

Influence of aluminum, lead, iron and tin in brass. I. ANON. *Z. Metallkunde* 21, 152-9 (1929).—The effect of Al, Fe, Pb and Sn upon brass is studied. 0.5 to 0.9% Al is used, Zn being replaced in the ratio 1Al = 4Zn; 0.2 to 2.0% Fe is merely added without change in Cu and Zn; this is likewise true of Pb (0.2 to 4.0%), while the content of 1 to 6% Sn investigated replaces Zn in the ratio of 1Sn = 3Zn. The results are as follows: Pb addn. strongly suppresses the values of reduction in area and strength in bending and torsion tests for brass contg. 57, 60 and 65% Cu. In the proportions used very little effect was obtained from Fe, other than a slight increase in mech. strength and decrease in elongation. With both 62 and 68% brass, replacement of Zn with Al produces an increase in tensile strength and a considerable decrease in elongation, reduction in area, and drawing ability. The replacement of Zn by structurally equiv. quantities of Sn produces improvement in mech. properties. The greatest influence is

upon elongation, the value of which is increased about 100% with a Sn content of 5%.

H. STOERTZ

**The properties of industrial gold alloys.** ERNEST A. SMITH. *Metal Ind.* (London) 34, 342-4, 352, 373-4 (1929).—An increase beyond 7% Zn in 9 carat Au tends to produce brittleness. Usually the hardest, strongest and best working alloy for any given carat is obtained by equal parts of Ag and Cu. Other proportions must sometimes be used for a desired color. Au with 60% Ag is quite white. An alloy of 90% Ag-10% Au is sold as white Au for gem setting. It holds its color longer than pure Ag. Green Au is made with 25% Ag. If 18 carat Au alloyed with 25% Cu cools slowly, a mol. change occurs rendering the alloy hard and brittle. Quenching the alloy above 400° gives a malleable and ductile metal. Other Au-Cu alloys show the same phenomenon to a lesser extent. The hardest of all triple alloys, Au 50, Ag 25 and Cu 25%, has a Brinell hardness of 150. When subjected to the same amt. of rolling, Au-Cu alloys harden more quickly than Au-Ag alloys. Usually all Au alloys are satisfactorily annealed by heating for a few minutes at 650° to 700°.

H. C. PARISH

**The melting of aluminum and its alloys in melting pots.** EDMUND R. THIEWS. *Metallbörse*, 19, 425-6, 481-2 (1929).—In melting Al and its alloys care must be taken to guard against the reaction of the metal with O, N, hydrocarbons and the material of which the pot is made. The presence of Fe and Si in the alloy formed is often very harmful. As fluxes, Na and K compds. with Cl or F are widely used. Iron and steel vessels of higher C and Si content are better than those of purer Fe, e. g., total C 3.5, combined C 0.40, Mn 0.80, S (max.) 0.15, P 0.50 and Si 2.25%. The addn. of 2% Cr increases resistance to action of furnace gases. Ordinary steel or semi-steel should never be used. Painting the pot with Al varnish is recommended. Fireclay and MgO mixts. have been used to coat the inside of the pots. Better results come from Ca(OH)<sub>2</sub> or CaO-graphite pastes rubbed into the walls with steel brushes.

W. C. EBAUGH

**Radiography of light metal alloys.** S. H. ANDERSON AND L. MARICK. Univ. of Wash. Eng. Expt. Sta., *Bull.* No. 49, 18 pp. (1928).—Work was undertaken to det. under what conditions of voltage, tube current and exposure best contrast is obtained for particular castings and shapes radiographed. The effect of various factors involved in technic of radiography are brought out.

E. I. S.

**Dilatometric investigation of the thermal effects on annealing duralumin and its structural components.** M. HAAS AND H. HECKER. *Z. Metallkunde* 21, 166-73 (1929).—Measurements are made with the Universal Dilatometer of Oberhoffer-Esser, and include duralumin, Al-Cu, Al-Mg<sub>2</sub>Si, Al-Cu-Mg<sub>2</sub>Si and the German duralumins 681, 681B and 681B <sup>1</sup>/<sub>2</sub>. Varying Mn content appears to be of small influence upon the dilatometer curves. The bend in the curves between 250° and 300° can be due only to the sepn. of Mg<sub>2</sub>Si from the supersatd. soln. The results show that an upper limit of 520° in the heat treatment is sufficiently high to take into soln. all of the hardening constituents (Mg<sub>2</sub>Si and CuAl<sub>2</sub>), and also indicate that working temps. for parts made of duralumin should not be above 200°.

H. STOERTZ

**Immersion or dip gilding on brass jewelry and novelties in a red or 14-carat gold shade.** JOSEPH TRISKA. *Monthly Rev. Am. Electroplaters' Soc.* 15, No. 8, 13-4 (1928); *J. Inst. Metals* 40, 638 (1928).

E. H.

**Comparison of the thickness of oxide layers determined from tempering colors and by weighing.** G. TAMMANN AND K. BOCHOW. *Z. anorg. allgem. Chem.* 169, 42-50 (1928).—From the thickness of an air layer sufficient to produce a color equiv. to the tempering color in question the thickness of the tempering color can be detd. by the equation  $d_f = l/n$ , where  $l$  = thickness of air layer in  $\mu\mu$ ,  $n$  = the refractive index of the tempering layer and  $d_f$  = the thickness of the tempering layer. By weighing a plate before and after tempering to a certain color, the thickness of the tempering film can be detd. according to the equation  $d_o = \frac{(\Delta g \times a \times 100)}{(S \times q)}$ , where  $\Delta g$  = increase in weight of plate,  $a$  = ratio of equiv. wt. of oxide formed to equiv. wt. of O,  $S$  = sp. gr. of oxide and  $q$  = area in sq. mm. If the metal surface in consideration were in such a condition, when the plate is weighed, as to be free from a layer which might affect the optically detd. thickness, then  $d_o$  would have to equal  $d_f$ . However, if this is not the case,  $d_f = d_o + d_a$ , where  $d_a$  is the thickness of a layer present upon the metal before tempering and upon the oxide layer after tempering. Expts. show that  $d_a$  is equiv. to an oxide layer of 80 to 120  $\mu\mu$  in thickness and that this layer is present before and after tempering. Ni plates 0.1-0.2 mm. thick were carefully polished and treated in an extn. flask with alc. and alc. vapor until the weight remained const. upon a microbalance. The plates were placed in heat-treating furnaces at the desired

temps. When the plates had been in long enough to attain the desired colors they were removed and weighed. Plates uniformly tempered were used since nonuniformity would give erroneous results. Errors of  $30\mu$  were not visible to the human eye and such errors did occur between different crystals of the metal sheet. Another set of expts was made by preheating the metal in an atm. of H to  $500^\circ$  or  $600^\circ$  and cooling in H, weighing to const. wt. and tempering to the desired color. Repetition of the reduction after tempering gave results in which the loss in wt. upon reduction was much less than in the first case. The mean difference  $d_f - d_g$  is about  $99\mu$  and is attributed to the existence of NiO, hydrated NiO, absorbed air and steam. Hence it is seen that there is present a layer of substance which apparently changes the thickness of the actual layer about  $100\mu$  when detd. by the temper color method. The difference for Cu was about  $91\mu$ , for Fe  $85\mu$ . Since the sp. gr. and  $n$  of FeO were not known, those of NiO were used in computation.

B. F. ROETHLI

**Rolled and welded-on coatings and oxidation of light metals.** F. RACKWITZ. *Z. ges. Gewerkspraxis* 50, No. 18 (*Das Metall*), 69-70(1929).—Metal coatings of different kinds can be advantageously applied to Fe-Al alloys and other metals by certain rolling processes. Plating of Fe with Al is carried out by the Jordan process, Al being applied under high pressure and then rolled down to plate thickness; or by the Trier process in which Al is cold-rolled on Fe. Al can also be applied in like manner to other metals. The protection of light metals by oxidation is discussed.

E. I. S.

**Recent progress in the study of corrosion.** G. D. BENGOUGH. *Chimie & Industrie Special No.*, 134-40(Feb., 1929).—An address reviewing Whitney's theory of corrosion and its modifications resulting from subsequent investigations, particularly by British and American investigators, and dealing only with corrosion by water and by salt solns.

A. PAPINEAU-COUTURE

**Anodic oxidation as a means for protecting aluminum valves from corrosion.** W. ELSNER v. GRONOW. *Gas. u. Wasserfach* 72, 429-36(1929).—Al valves and similar articles may be protected from corrosion by a surface film formed by electrolysis in  $3\%$  chromic acid or similar solns., with a potential up to 50 v. and with a c. d. of 0.3 to 0.4 amps. per sq. dm. for pure Al, although many alloys require a greater current. The temp. should be held at  $40 \pm 2^\circ$  or defective coatings will result. Alloys contg. over 5% Cu cannot be protected by this method.

R. W. RYAN

**Corrosion experiments with iron.** WILHELM VAN WÜLLEN SCHOLTEN. *Gas u. Wasserfach* 72, 456-8(1929); cf. *C. A.* 23, 83.—A review of exptl. technic and theory of iron corrosion, with 33 literature references.

R. W. RYAN

**The corrosion of metals and light metals by [liquid] fuels.** ERICH K. O. SCHMIDT. *Auto-Tech.* 16 (15) 7-9(1927); *Metallbörse* 17, 623-4, 681-2; *J. Inst. Metals* 39, 522. Expts. on the corrosion of steel, Cu, brass, Al, duralumin and other metals by benzene, benzene, alc. and various mixts. are described and discussed.

H. L. D.

**Results of investigations to establish the cause of the corrosion of sheet metal by motor fuels.** WAWRZYNOK. *Auto-Tech.* 16 (21), 23-25; (22), 19-28(1927); *J. Inst. Metals* 39, 522.—Although tin resists the corrosive action of motor fuels, it does not necessarily protect other metals from this action when it is used as a coating metal Pb and Zn protective coatings are practically completely removed by prolonged contact with gasoline and gasoline-alc. mixts. Certain brands of Al sheet and the non-rusting V2A steel behave satisfactorily, but the effect of lapping, welding and riveting these metals has not yet been studied.

H. L. D.

**The resistance of some metals to the action of nitric acid.** W. SCHMIDT. *Metallbörse* 17, 2415-6(1927).—W. describes various expts. on the corrosion of Al, Al alloys, Cr-Fe, Cr-steel, Cr-Ni-steel and various alloys by  $\text{HNO}_3$  of different concns., and discusses the results.

H. L. D.

**The application of cadmium as rust-protecting medium by the Udylyte method.** EDWARD D. FELDMAN. *Metallwaren-Ind. u. Galvano-Tech.* 26, 8-9(1928); *J. Inst. Metals* 39, 589.—The properties of Cd are discussed. The advantages of Cd deposits over the Ni and Zn deposits for the protection of various metals against rust are dealt with. In expts. on comparative rust resistance, rust was produced on Ni-plated articles after 2 hrs., on hot zincd articles after 650 hrs., and on Udylyte-plated articles after 1860 hrs. Cd is specially good as a between-deposit of metal in various compd. electroplating methods. Cd-Cr plating has many advantages. The Udylyte method is described, the compn. of the electrolyte is considered, and the production of glossy and matt deposits is dealt with.

H. L. D.

**Electrical cleaning of blast-furnace gas (DURRER) 4. Using blast-furnace gas for heating (EBNER) 21. Prevention of boiler corrosion by the addition of alkalis (SPITT-**

GERBER) 14. Fuel problems of the iron and steel industry (EVANS) 21. The use of MeOH and EtOH as fuels in internal-combustion engines (LOUIS) 21. D. V. L. pressure cylinder and its use (RACKWITZ, SCHMIDT) 1. A new determination of the melting point of Pd (FAIRCHILD, *et al.*) 2. Research findings on corrosion and vitamin destruction (KOHMAN) 11E. New uses for Cd [as anti-corrosive material] (FRANK) 18. Xanthates [for use in flotation] (U. S. pat. 1,716,273) 10. Briquetting ores (Ger. pat. 476,319) 21. Hydrogenation apparatus (Fr. 653,135) 1.

**Arc Welding.** Lincoln Prize Papers submitted to the Am. Soc. of Mech. Engineers. Edited by EDWARD P. HULSE. New York: McGraw-Hill Book Co. 421 pp. \$5.

BRAY, JOHN L.: **Principles of Metallurgy.** Boston: Ginn & Co. 568 pp. \$5.80.

HENTZE, E.: **Sintern, Schmelzen und Verblasen sulfidischer Erze und Hüttenprodukte.** Berlin: V. D. I. Buchhandlung. Bound, M. 46.50.

**Ore treatment.** FRIED KRUPP GRUSONWERK A.-G. Ger. 475,749, Sept. 11, 1925. Ore briquets are formed by running the ore paste on to a rotary molding drum.

**Apparatus for classifying ore constituents by water currents of increasing strength.** BYRON M. BIRD. U. S. 1,715,693, June 4.

**Separating ores from gang by an upward current of air.** GEORGE RAW. Fr. 654,677, May 24, 1928.

**Mineral concentration by flotation.** ELMER K. BOLTON (to E. I. duPont de Nemours & Co.). U. S. 1,716,104, June 4. Sulfides such as those of Pb and Zn are subjected to froth flotation in the presence of a metal salt of 1-mercaptobenzothiazole, *e. g.*, the Na or Zn salt.

**Reduction of ores.** THOMAS ROWLANDS. Fr. 653,808, May 3, 1928. See Brit. 295,338 (C. A. 23, 2143).

**Reducing complex ores.** FRANK O. KICHLINE (to Bethlehem Steel Co.). U. S. 1,717,160, June 11. Complex ores (such as Mayari Fe ore of Cuba) contg. reducible components not widely different in their reduction temps. are heated with sufficient reducing agents such as C or H substantially to reduce such of the more readily reducible components, *e. g.*, Ni and Fe, as it may be desired primarily to sep. from the ore; the temp. for this purpose is lower than the fusion temp. of the desired component. The mass is then heated to a higher temp. at which a substantial agglomeration of the metallic particles may be effected, and is then cooled and crushed, the metallic agglomerate is sep'd. from the unreduced material and the latter is subjected to a secondary reduction by further heating with a reducing agent such as coal, *e. g.*, to reduce Cr.

**Iron ores.** STAALSYNDICAAT LEDEBOER. Fr. 653,261, Mar. 22, 1928. See Brit. 287,925 (C. A. 23, 366).

**Treatment of chrome iron ore.** KURT HELMHOLZ. Ger. 476,397, Nov. 26, 1927. Chrome iron ore is opened up by heating with  $\text{HPO}_3$  or  $\text{H}_3\text{P}_2\text{O}_7$  to about  $300^\circ$ . If the heating is interrupted as soon as a sample of the melt gives a deep green color on cooling, a transparent product is obtained which may be freed from  $\text{SiO}_2$  by soln. in water, filtered, and then worked up. If, however, the heating is continued, a sparingly sol. opaque product is obtained useful as a pigment or enamel. Suitable initial proportions are ore 1 and  $\text{H}_4\text{P}_2\text{O}_7$  8 parts.

**Zinc ores.** REAL COMPAÑIA ASTURIANA DE MINAS. Fr. 654,463, May 19, 1928. Zn ores are roasted in ordinary furnaces to a content of 2-3% of S, and to the mass is added (1) crude ground calamine, contg. as much Fe and Si as possible, to render the charge fusible and porous, (2) about 7% of ground coke from reduction furnaces, or about 5% of fine coal. The charge thus agglomerated is then heated in superroasting furnaces.

**Metal founding.** ROBERT B. DALE. Ger. 475,770, Sept. 12, 1926. A device for regulating the cooling of a centrifugal mold pre-heated by Hg vapor is described.

**Metal founding.** EISEN UND STAHLWERK HOESCH. A. G. Ger. 475,593, May 5, 1927. A comp'd. casting is made by introducing a block of hard steel into the center of a mass of molten steel.

**Metal founding.** LUDW. LOEWE & Co. A.-G. Ger. 475,591, Mar. 21, 1925. Automatically cooled molds are described.

**Metal founding.** METALLGESELLSCHAFT A.-G. (Emil Lay, inventor). Ger. 475,841, Feb. 19, 1927. A method and app. for producing rollable double-metal castings by heating the foundation metal in the mold and pouring it on the covering metal are described.

**Two-part stop-frames for metal founding.** HEINRICH HEPPERLE. Ger. 475,590, Dec. 29, 1927. Structural details are given.

**Fusion crucibles for metals or alloys.** DEUTSCHE GOLD- UND SILBER-SCHNEID-ANSTALT VORM. ROESSLER. Fr. 653,995, May 8, 1928. A method of gas heating is described.

**Machine for casting metals.** JOSEF POLÁK and HEINRICH TALLA. Ger. 476,093, Sept. 3, 1927.

**Machine for casting difficultly fusible metals.** MIGUEL C. VALLS and JOSÉ S. ESTELLER. Ger. 476,094, Feb. 10, 1927.

**Pressure-casting machine with an electrically heated crucible.** KUNO WELSCHER. Ger. 475,595, June 4, 1925. Details of arrangement are given.

**Casting gears.** CARL H. RICH (to Riley Stoker Corp.). U. S. 1,716,833, June 11. In casting a rim of bronze around an iron center placed in a mold, molten metal is poured into contact with the center evenly to heat it and to cause it evenly to expand and contract during the operation. An app. is described.

**Apparatus for casting ingots.** EDWIN C. WASHBURN. Fr. 654,379, May 16, 1928.

**Ingots.** EISEN- UND STAHLWERK HOESCH A.-G. Fr. 653,700, May 2, 1928. Ingots which are chemically and physically pure are obtained by bringing the cast ingots after the first cooling with liquid nucleus into a shaft with high-frequency elec. heating which quickly regulates the temp. To obtain a smooth surface the shaft is first heated so that the outer crust melts. The ingots are kept liquid from the interior out, the exterior crust being kept solid by a current of air between the ingot and the internal walls of the shaft. By the manner of treatment the liquid nucleus receives a rotating movement so that gas is eliminated and a uniform mixing takes place. The final cooling is regulated to give a uniform solidification which is detd. according to the compn. of the steel.

**Vertical ingot mold and stool.** JOHN E. PERRY (to Valley Mould & Iron Corp.). U. S. 1,715,620, June 4. Structural features.

**Pin and socket guide for a metal mold.** JAMES F. HINES. Ger. 475,589, May 7, 1926.

**Mechanical furnaces for roasting ores.** JOHN HARRIS. Fr. 654,513, May 21, 1928.

**Metallurgical furnace suitable for steel manufacture.** BENJAMIN TALBOT. U. S. 1,716,391, June 11.

**Coal-dust-consuming furnace for the heat treatment of iron and steel.** PETER LAUSEN. Ger. 476,146, Nov. 12, 1926.

**Blast furnace.** WALLACE A. STUART (to Inland-Stuart Linings, Inc.). U. S. reissue 17,325, June 11. See original pat. No. 1,632,633 (C. A. 21, 2455).

**Device for indicating the height of the charge in a blast furnace.** SIEMENS-SCHUCK-ERTWERKE A.-G. (Franz J. Mosch, inventor). Ger. 476,841, Dec. 15, 1925.

**Checkerwork construction for hot-blast stoves, etc.** EARL G. WHELPLEY (to Shea-Whepley Construction Co.). U. S. 1,715,969, June 4.

**Siemens-Martin and fusion furnaces.** OTTO G. KARRENBERG and HERMANN RÖMER. Fr. 653,977, May 8, 1928. Construction of a roof is described.

**Open-hearth furnace.** THOMAS J. JAMISON. U. S. 1,717,107, June 11.

**Cupola furnace.** FRIEDRICH W. CORSALLI. Ger. 475,948, Dec. 8, 1925. A device for catching the molten iron flowing from the shaft is provided in the forehearth.

**Cupola furnace.** KARL SCHMIDT. Fr. 652,697, Apr. 14, 1928.

**Cupola-furnace operation.** KARL GROCHOLL. Ger. 476,414, May 17, 1928. A part of the melt descending the furnace is intercepted between the melting zone and the tuyère zone and is conducted to the hearth or forehearth without traversing the tuyère zone. A suitably constructed furnace is described.

**Reversing device for a regenerative furnace consisting of inverted U-shaped gas conducting tubes.** FRANCISQUE PAUL ROUSSEL. Ger. 475,577, July 7, 1925.

**Annealing furnace for metals.** ARTHUR T. KATHNER. Fr. 653,379, Apr. 24, 1928.

**Continuous furnace for annealing wire.** WILLIAM M. HEPBURN and ERNEST W. WEAVER (to Surface Combustion Co.). U. S. 1,716,956, June 11. Structural features.

**Packing for a metal-annealing muffle furnace.** ERICH G. KÖHLER. Ger. 476,858, June 16, 1926.

**Galvanizing furnace.** FIRMA N. FRITZNER. Ger. 476,107, Sept. 8, 1928. A furnace for melting Zn is constructed so that the heating gases are directed against the sides of the crucible while the Zn is protected against overheating by a blast of air directed against the bottom of the crucible.

**Treatment of metals.** SIGURD WESTBERG. Ger. 476,513, Apr. 30, 1928. Metals and alloys, especially Fe and steel plates, bands and wires, are hot-worked in an atm. of H in the presence of a substance such as oxides of Al, Ca, Ba or Sr which decompose or absorb compds. (as of S or P) formed on the metal surface during the working.

**Separating metals.** JULES BICHON and LOUIS BERGOGNON. Fr. 653,981, May 8, 1928. Bronzes or alloys contg. Sn or Sb are melted and oxidized at a high temp in the presence of sand which combines with the oxides formed, or  $\text{Na}_2\text{CO}_3$  which dissolves them. The Cu remaining is refined in known manner. The slag contg. the oxides is melted in a reducing medium to obtain an alloy of the other metals, which is submitted to fusion with alk. sulfide to transform the metals to sulfides, and these are sepd. by chem. treatment of their soln. in water.

**Separating tin, lead, antimony, copper and zinc from alloys, etc.** FRANZ BISCHITZKY. Austrian 112,963, Dec. 15, 1928. The known method of sepg. Sn, Pb, Sb, Cu and Zn from alloys, mixts., ores, scrap, etc., contg. them in which the alloy, etc., is dissolved as far as possible in hot HCl is improved by addn. of non-oxidizing salts, *c. g.* chlorides, phosphates or borates, to the acid. These addns. act catalytically. Cf. C. A. 23, 370.

**Precipitating metals on surfaces.** NAAMLOOZE VENNOOTSCHAP PHILIPS' GLOELAMPENFABRIEKEN. Fr. 654,563, May 22, 1928. The metals Rh, Ir, Os and Ru are pptd. on surfaces of W, Mo, C, Ni, etc., by heating the surface in an atm. contg. volatile compds. of the metals, particularly halogen or carbonyl compds.

**Removal of sulfur from nickel and copper-nickel.** THE INTERNATIONAL NICKEL CO. Ger. 476,814, July 21, 1926. S is removed from coarse Ni and Ni-Cu by a blast of gas which is weakly oxidizing, weakly reducing or indifferent in action. The app. is described.

**Pure metals.** I. G. FARBENIND. A.-G. Fr. 33,809, June 30, 1927. Addn. to 609,204. Pure Fe is obtained by allowing the liquid carbonyl to fall on to a liquid such as liquid paraffin heated to  $270^\circ$ . According to Fr. 33,811 the process of Fr. 609,204 is applied to the prepn. of other metals such as Co, Ni or Mo.

**Titanium compounds.** I. G. FARBENIND. A.-G. Fr. 653,893, May 5, 1928. See Can. 285,355 (C. A. 23, 673).

**Recovery of tin.** HÜTTENWERKE TROTHA A.-G. and WILHELM WITTER. Fr. 653,669, May 1, 1928. Sn is recovered from material contg. oxides of Sn and Pb by heating with caustic alkalies to a temp. of  $300\text{--}450^\circ$  to insure the formation of alkali stannates. A little C may be added to the starting materials. The mass is afterwards treated with water only sufficient to dissolve out the excess alkali.

**Zinc.** ALEXANDER ROITZHEIM and WILHELM REMY. Ger. 476,153, Apr. 29, 1926. See Brit. 294,127 (C. A. 23, 1861).

**Cast iron.** EUGEN PIWOWARSKY (to Vereinigte Stahlwerke A.-G.). U. S. 1,715,509, June 4. In producing high-grade cast iron from pig iron of grades such as have ordinarily been cast in sand and exhibit a gray fracture, a predominantly white solidification is obtained by casting in chill molds having a cross-sectional area of less than 100 sq. cm. and causing such amts. of graphite as may remain after solidification to be dissolved by remelting at a high temp. Cf. C. A. 22, 1754.

**Cast iron.** WERNER STAUFFER. Swiss 130,201, Feb. 3, 1928. Cast iron of a high tensile strength and contg. 2.6–3.2% C is prepd. in a cupola from a mixt. comprising not less than 30% of special pig iron contg. about 2.5% C, 10–30% steel (these two constituents together not exceeding 70%) and not less than 30% of the usual pig or scrap iron. The air blast is kept constant. Cf. C. A. 22, 4452.

**Low-carbon chromium steel.** HENRY C. BIGGE and CHARLES R. ELLICOTT (to Bethlehem Steel Co.). U. S. 1,715,979, June 4. In prepg. a low-C ferrous alloy contg. a metal of the Cr group normally tending to be "wild," a reducing agent such as ferro-S is added to the slag to produce a strongly exothermic reaction and the alloy is poured while the thermal effects of the reaction still persist in the slag.

**Ferro-vanadium.** BYRAMJI D. SAKLATWALLA (to Vanadium Corp. of America). U. S. 1,715,867, June 4. A ferro-V contg. 85–95% of V is prepd. for use in making V alloy steels, etc.

**Desulfurizing steel.** CHARLES T. HENNIG. U. S. 1,717,153, June 11. Soda is mixed into molten iron forming part of the charge for making steel prior to its introduction into an open-hearth furnace which causes the metal to be violently agitated and boiled by gases given off by the soda and forms a soda-contg. slag on the metal which is of relatively higher fluidity than the ordinary basic slag; the iron thus treated, together with the slag on it, is then run into a bath of partially refined metal in the open hearth furnace and the boiling of the metal is continued in the open-hearth furnace until the oxides and sulfides have been eliminated from the metal to the required extent.

**Galvanizing steel.** EVAN A. ATKINS. Fr. 654,849, May 25, 1928. Steel is galvanized by passing it into a bath of molten Pb at a temp. such that the steel is made

red hot, and then plunged into molten Zn or a Zn alloy without coming in contact with the atm.

**Galvanizing apparatus.** VEREINIGTE ELEKTROCHEM. FAB. OSKAR HAHN. Ger. 475,975, Mar. 2, 1928. A device for plunging a number of articles together into the bath is described.

**Copper sulfate.** MAX SPEICHERT (to Hüttenwerke Tempelhof A. Meyer). U. S. 1,715,871, June 4. An alloy composed of Cu, Sn, Pb and Sb (such as a scrap metal) is melted with S to produce a mixt. of sulfides of the metals, the sulfide mixt. is roasted, the roasted product is leached with  $H_2SO_4$  and the soln. contg.  $CuSO_4$  is sepd. from the insol. residue.

**Alloys.** THE BARBER ASPHALT CO. Fr. 653,899, May 5, 1928. An alloy capable of resisting almost completely the action of  $HNO_3$  contains Ni 20-40, Fe 30-50, Cr 15-25 and 10% of a modifier which may be Si, Mn, W, Cu or Co. An example gives Ni 30, Fe 40.8, Cr 21, W 6.2, Si 0.45, Mn 1.55%. Fr. 653,900 describes a similar alloy, an example of which contains Ni 20, Fe 56, Cr 14.5, Co 5, Cu 4.5%. Fr. 653,901 describes a similar alloy, an example of which contains Ni 53, Fe 23, Cr 15, W 4, Mn 1.25, Si 3.75%. Cf. C. A. 23, 3434.

**Alloys.** THOMAS H. KELLY. Fr. 654,336, May 15, 1928. See Brit. 281,950 (C. 1 22, 3624).

**Alloys.** LÉO KLÜGER. Fr. 653,290, Apr. 21, 1928. An alloy which is not affected by repeated heating to 1200° contains C more than 1, Ni 40-50%, Cr  $\frac{2}{3}$  of the amt of Ni present, Fe the rest.

**Alloys.** SIEMENS & HALSKE A.-G. Fr. 653,460, Apr. 26, 1928. A magnetic alloy contains Ni (or Co) 30-80, Si 1-20, Fe 20-70%. An example gives Ni 78.5, Si 4, Fe 17.5%. A high permeability is obtained by reheating the alloy to about 900° for a long time, slowly cooling to about 625°, maintaining it at this temp. for a long time and then rapidly cooling to ordinary temp.

**Fire-resistant alloy of high electrical resistance.** HANS G. A. VON KANTZOW. U. S. 1,717,284, June 11. An alloy which is suitable for elec. resistance heaters comprises as its main constituents Fe together with Al 0.5-14, Cr 30 or less and Co 0.5-6%.

**Aluminum-beryllium alloy.** ROBERT S. ARCHER and Wm. L. FINK (to Aluminum Co of America). U. S. 1,716,943, June 11. An Al base alloy contg. Be is heated to a temp. slightly below the m. p. of the Al-Be eutectic to cause substantial soln. of the undissolved Be constituent of the alloy, and is then quenched from substantially such a temp.

**Aluminum-silicon alloys.** METALLGES. A.-G. Ger. 476,384, Nov. 27, 1921. Al Si alloys contg. more than 2% Si are rendered suitable for casting by addn. of 2-6% Cu and (or) more than 5% Zn, care being taken that the incidental content of Fe does not exceed 1%. Suitable alloys contain Si 6 and Cu 4%, or Si 8 and Zn 10%, or Si 8, Zn 10 and Cu 2.5%.

**Brass alloy.** METALLGESELLSCHAFT A.-G. Ger. 476,962, Aug. 20, 1924. A brass alloy suitable for foundry work contains Cu 50-56%, Si 0.1-0.8% and Sn 0.1-0.4%.

**Copper-aluminum alloys.** OSNABRÜCKER KUPFER- UND DRAHTWERK. Ger. 476,481, Jan. 1, 1927. Cu-Al alloys for the autogenous welding of Al bronze contain Al up to 15 and an alkali metal up to 2%. A suitable alloy contains Cu 96, Al 4 and Na 0.3 parts.

**Alloys of iron.** BYRAMJI D. SAKLATWALLA. Fr. 653,860, May 4, 1928. See Brit. 288,861 (C. A. 23, 594).

**Iron alloys.** VERE B. BROWNE. Fr. 652,949, Apr. 17, 1928. Fe alloys contg. Cr and Al, specially those contg. Cr 5-30, Al 3-10% and little C, are worked from the ingot by forging or rolling in a series of stages with gradually reducing temp. from a starting temp. of 1100°. The final working may be carried out in the cold, and the alloy may be annealed by heating to a temp. below 870°. The process yields an alloy which is ductile and resists oxidation at high temps.

**Iron alloys.** CENTRAL ALLOY STEEL CORP. Fr. 653,686, May 2, 1928. The physical properties of an Fe alloy contg. Cu and Mo are improved by adding to the molten alloy a proportion of Mn such that 0.2-1% of Mn remains in the alloy, which contains C less than 0.2, Cu 0.2-2 and Mo up to 0.2%. Si (up to 0.5%) is introduced, and Al in amt. such that only a trace remains in the final alloy. The amt. of S and P should be less than 0.04% of each.

**Alloy pig iron.** HARRY P. PARROCK. U. S. 1,716,181, June 4. A method of producing pig iron suitable for making alloyed pig iron without disturbing the normal operation of the blast furnace comprises smelting ore in a blast furnace, transferring a portion of the molten iron to an open-hearth furnace where it is heated to a high temp., separately melting a relatively small quantity of alloying metal such as ferro-Ni, and,

without further treatment of the produced molten iron, adding the alloying material to the metal in the open-hearth furnace; the alloyed pig iron is cast, and, meanwhile, the undiverted portion of the molten iron from the blast furnace is also cast. An arrangement of app. is described.

**Alloys containing zinc, nickel and copper.** WILLIAM M. GROSVENOR and VICTOR P. GERSHON (Gershon to Grosvenor). U. S. 1,716,050, June 4. Alloys which are suitable for use in making "white gold" comprise Zn about 20, Ni 70 or more, and Cu 9% or less.

**Device for the hot rolling of metals and alloys.** WILHELM HAMMER. Ger. 475,931, May 15, 1927. Details are given.

**Method of annealing.** AKTIEN GESELLSCHAFT BROWN, BOVERI & CIE. Swiss 130,736, Dec. 8, 1927. Metal objects are subjected to a continuous glowing heat in a gas atm. with exclusion of air. The furnace comprises radially arranged chambers into which the objects are placed, and the heat in the annealing chamber is used to pre-heat the cold objects in an adjacent chamber.

**Hardening one surface of metal blanks (such as those for making brake drums) preparatory to bending.** NATHAN H. SCHERMER and CHARLES G. HEILMAN. U. S. 1,716,191, June 4. Blanks are arranged in spaced pairs with adjacent surfaces of the members of each pair in contact and are carbonized on one side only with the non-contacting surfaces exposed to the action of a hardening medium.

**Treatment of aluminum surfaces.** BOHUMIL JIROTKA. Ger. 475,789, Mar. 2, 1927. Al and its alloys are given an oxidized surface by treatment in the cold with a bath contg. HF and a chromate. The appearance of the surface is improved by inclusion of a heavy metal salt. A suggested bath contains HF 2,  $\text{Na}_2\text{Cr}_2\text{O}_7$  5 and  $\text{CuSO}_4$  0.5% per l.

**Mechanically worked zinc product.** WILLIS M. PEIRCE and EDMUND A. ANDERSON. (to New Jersey Zinc Co.). U. S. 1,716,599, June 11. Sheet metal or other mech. worked products are formed from a Zn base alloy substantially free from Al and contg. not less than Zn 92, Mg 0.005–0.5 and Cu 0.05–5%.

**Magnetic material.** GUSTAF W. ELMEN (to Bell Telephone Laboratories). U. S. 1,715,541, June 4. A magnetic material suitable for use in elec. signaling systems comprises Fe, Ni and Co (suitably in the relative proportions of 22–25, 40–50 and 20–30, resp.) and possesses a high degree of constancy of permeability over a range of magnetizing forces including that employed in continuous loading of elec. signaling conductors; at least one of the following elements is also added to increase the resistivity: Mo, Cr, W, Mn, V, Ta, Zr, Cu and Si. U. S. 1,715,542 relates to elec. coils with cores characterized by incremental permeability at low magnetizing forces, greater after being subjected to a large direct magnetizing force than before. Such cores may be formed of Ni 45, Co 25 and Fe 30%. U. S. 1,715,543 specifies cores formed mainly of Fe, Ni and Co (suitably in the relative proportions of 10–45, 20–70 and 10–50%, resp.) and which may also contain Mo, Cr, W, V, Ta, Zr, Cu, Si, Al, Mn, etc. Cf. C. A. 23, 2692.

**Magnetic material.** GUSTAF W. ELMEN (to Western Electric Co.). U. S. 1,715,646, June 4. A magnetic material suitable for use in signaling circuits comprises essentially Ni, Co and Fe, with a Ni content 65–80% of the total Ni-Co-Fe content. U. S. 1,715,647 specifies a magnetic material including at least 2 magnetic elements such as Ni, Co and Fe which may be in about the relative proportions of 60, 15 and 25%, resp., having negligible variation in permeability over a range of flux densities at least 50 c. g. s. units in width and lying between zero as a lower limit and 5000 c. g. s. units as an upper limit. U. S. 1,715,648 (assigned to Bell Telephone Laboratories) specifies a compn. formed mainly of Fe, Ni and Co, including 9% or more Fe, 4% or more Ni and Co, with or without addn. of a fourth substance such as Mo or Ti to increase the resistivity or modify other properties; the Co content is over 45% of the Fe-Ni-Co content but not in excess of 80% of the entire compn. Cf. C. A. 23, 1105.

**Treating magnetic materials.** VICTOR E. LEGG (to Bell Telephone Laboratories). U. S. 1,715,713, June 4. Magnetic materials such as alloys of Fe, Ni and Co for use in signaling systems are subjected to the simultaneous influence of a d. c. field and an a. c. field, and the direction of the d. c. field is periodically reversed, to restore their properties when abnormally magnetized.

**Apparatus for pickling metal articles.** LEIF LEE. U. S. 1,716,068, June 4. Structural features.

**Separating stacked metal sheets.** VICTOR G. ROSS (to Continental Can Co.). U. S. 1,716,602, June 11. Sheets of metal such as tin plate are subjected to a magnetic field to render them mutually repellent and facilitate their sepn.

**Linings for internal-combustion engines.** EDWARD SOKAL. Ger. 475,974, July 19, 1925. An antiknocking coating for the cylinders of internal-combustion engines is composed of readily fusible metals such as Pb, Sb or Te with a binding material of such substance as silicate.

**Production of hollow metal ware by centrifugal apparatus.** FERNANDO ARENS. Swiss 131,151, Dec. 16, 1927.

**Continuously operating plant for coating tubes or bars with metal or other coatings.** GOTTFRIED BUCHERT. Ger. 473,020, July 9, 1926.

**Apparatus for coating wires, bands, etc.** WERNER & MERTZ A.-G. Ger. 476,037, Apr. 6, 1927. The wire, etc., is passed first through a bath of coating compn., then through a hole in a Fe plate, then again through the bath, then through another hole in the plate, and so on, the holes being of different sizes so that coatings of different depths can be obtained. A series of baths may also be used. Cf. C. A. 23, 369.

**Coating small articles such as those of radio apparatus with metals such as tin or zinc.** CHARLES E. JONES (to General Electric Co.). U. S. 1,717,220, June 11. See Brit. 279,092 (C. A. 22, 2736).

**Corrosion preventing.** I. G. FARBERIND. A.-G. Fr. 652,899, Apr. 16, 1928. Surfaces of Fe are protected by treating them with a powd. alloy of Al and Cr (Al 15, Cr 85%) at about 1000° in a reducing atm. Cf. C. A. 23, 3435.

**Rust preventing.** LOUIS HUBER and HUGUES WOLFF. Fr. 653,635, May 1, 1928. Fe is cleaned and heated to a convenient temp. and coated with a layer of lignite tar.

**Removing rust and scale from ferrous metals.** WILLIAM H. COLE. U. S. 1,715,695, June 4.  $\text{H}_3\text{PO}_4$  soln. of such diln. is applied that no coating is left on the articles when they are treated, in a closed vessel, at boiling temp. and under pressure.

**Brazing flux.** JOHN J. PHELAN (to General Electric Co.). U. S. 1,717,250, June 11. A brazing flux suitable for brazing Cr alloys comprises at least 25% K acid fluoride and at least 40% K tetraborate, and may also contain other alkali fluorides and borates.

**Welding rods containing copper, zinc and silicon.** ARTHUR R. LYTLE (to Union Carbide & Carbon Research Laboratories). U. S. 1,716,590, June 11. Welding rods for use with brass and bronze alloys, etc., comprise Cu and Zn together at least 82.5% (the Cu content being 55-65%) and Si 4% or less.

**Electric welding.** SVEN R. BERGMAN (to General Electric Co.). U. S. 1,716,614, June 11. An arc is maintained to heat the parts to be welded, a gaseous medium such as H is preheated to increase its volume and this gaseous medium is applied to the arc and molten metal.

## 10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

**Recent advances in science: Organic chemistry.** J. N. E. DAY. *Science Progress* 23, 585-8(1929); cf. C. A. 23, 1384.—A review of recent work in org. chemistry, chiefly with reference to dyes of the cyanine group, pseudoaconitine, and selenophene.

**Modern viewpoint in regard to theories of aromatic substitution.** W. A. WATERS. *Science Progress* 23, 649-54(1929).—A review.

JOSEPH S. HEPBURN

**Chemistry of the cracking process.** A. N. SACHANEN (SAKCHANOV) AND M. D. TILICH'EV. Ber. 62B, 658-77(1929); cf. C. A. 23, 963.—To get light on the chemistry of the cracking of naphtha and naphtha oils, which consist almost exclusively of  $\text{C}_{14}$  and aromatic hydrocarbons and naphthenes, the cracking of individual representatives of these groups of compds. has been studied. The expts. were carried out in an Fe autoclave provided, between the autoclave and the condenser, with a reducing valve by means of which the pressure could be regulated by letting out some of the decompn. products. Paraffin, m. 53°, was cracked at 425-50° for 60-180 min. At 425° under 10 atm. the gaseous products contain practically no  $\text{H}_2$  (0.5-1%), with 68-72%  $\text{CH}_4$  hydrocarbons; at 450° under 15-25 atm., 22-23%  $\text{H}_2$ , 0.25-2% CO and 59-61%  $\text{CH}_4$  hydrocarbons; the yield of products lighter than the original paraffin is excellent (95% or more). As no  $\text{H}_2$  and C are formed the decompn. can take place only according to the scheme  $\text{RCH}_2\text{CH}_2\text{CH}_2\text{R}' \rightarrow \text{RCH}:\text{CH}_2 + \text{MeR}'$  and not according to either  $\text{RCH}:\text{CH}_2\text{CH}_2\text{R}' \rightarrow \text{RMe} + \text{MeR}' + \text{C}$  or  $\text{RCH}_2\text{CH}_2\text{CH}_2\text{R}' \rightarrow \text{RCH}:\text{CH}_2 + \text{CH}_2:\text{CHR}' + \text{H}_2$ . There is practically no condensation; that observable in the expts at higher pressures is to be ascribed to the formation of unsatd. hydrocarbons. The cracking distillate contains about 50% unsatd. hydrocarbons, this proportion remaining

nearly const. in the 50° fractions from 30° to 300°; after removal of the unsatd. hydrocarbons with  $\text{H}_2\text{SO}_4$  the residue consists almost exclusively of normal paraffins. In the cracking of the paraffin the 220–40° fraction is the largest, indicating that the cleavage occurs chiefly in the middle of the mol. The more quickly the cracking products are removed from the field of reaction the smaller will be the amt. of polymers and naphthenes formed by condensation of the unsatd. hydrocarbons. Increase in pressure will therefore result in a decrease of unsatd. hydrocarbons; in expts. under 10 and 40 atm. the I no. of the resulting benzene was 107.8 and 58.8, resp. (Iso-Am)<sub>2</sub> heated 63 mins. at 425° (original pressure, 83 atm., increasing to 121 atm.) gave gases contg. 12% unsatd. hydrocarbons, 6.5% CO, 20.0%  $\text{H}_2$  and 61.5%  $\text{CH}_4$  hydrocarbons (by difference). The liquid products yield 4.9% of a fraction, b. 25–45° (isoamylene and isopentane), 6.1% b. 45–75° (hexanes, 22.9% unsatd.), 5.7% b. 75–125° (heptanes and octanes, 48.8% unsatd.) and 1.0% b. 125–45°. The small amt. of unsatd. hydrocarbons in the 45–75° fraction is probably due to partial polymerization of the olefins; an appreciable quantity of higher boiling fractions is also formed. Cracking of aromatic hydrocarbons without side chains results only in condensation; if they have side chains, the cracking can proceed in 2 directions.  $\text{C}_6\text{H}_6$  could not be studied in the liquid phase because of its low b. p.; in the vapor phase Berthelot obtained  $\text{Ph}_2$ .  $\text{C}_{10}\text{H}_8$  was practically unchanged when heated 3 hrs. at 425°; the pressure remained const. at 30 atm. At 475° the pressure rose only very slowly from 25–50 atm. in 4 hrs. 20 mins.; no C was liberated but crystn. of the 415–36° fraction (1.6%) yielded (2- $\text{C}_{10}\text{H}_7$ )<sub>2</sub>, m. 181–2.5°. Anthracene heated 2 hrs. 37 mins. at 475° (pressure up to 70 atm.) yielded gaseous products and changed into a compact, hard, coke-like mass, 59% of which (54.7% of the original) was insol. in hot  $\text{C}_6\text{H}_6$ . This very great difference in the thermal stability of  $\text{C}_{10}\text{H}_8$  and anthracene explains in great part the differences in the tendency to coke formation in the cracking of naphthas obtained from different fractions. With cymene heated 3 hrs. at 425° the pressure rose only from 85 atm. to 90, the d. hardly changed, and the yield of volatile products (including gases and loss in distn.) was not more than 10%; the gases (10 l. from 500 g. cymene) contained 1.1% unsatd. hydrocarbons, 2.3% CO, 68.5%  $\text{H}_2$  and 28.1%  $\text{CH}_4$  hydrocarbons (by difference). No  $\text{C}_6\text{H}_6$  was formed; about 1% PhMe and 3% xylene were obtained. The residue b. above 180° (6.2%) had a d. considerably higher (0.913) than the corresponding residue (d. 0.888) of the original cymene, indicating that condensation processes took place during the cracking. From 400 g. tetralin at 425° (pressure, 35–40 atm.) for 3 hrs. was obtained 2 l. gas contg. 89.2%  $\text{H}_2$  and 10.8%  $\text{CH}_4$  hydrocarbons. Heated 19 hrs. 40 mins. at 450° (pressure, 50–100 atm.), it gave 18.2% gases (and losses), 25.1% hydrocarbons of lower b. p., 14.1% of unchanged tetralin, 23.3% of  $\text{C}_{10}\text{H}_8$ , 10.4% of tetralin condensation products, 8.9% loss in fractionation. The decompn. therefore proceeded in 3 directions: Splitting off of the side chain with formation of  $\text{C}_6\text{H}_6$  homologs, 55%; dehydrogenation of the side chain and formation of  $\text{C}_{10}\text{H}_8$ , 30%; formation of condensation products, 15%. A naphthene mixt. b. 245–94°, obtained from an almost paraffin-free fraction of vaselin oil treated with  $\text{H}_2\text{SO}_4$ , when heated 62 mins. at 425° under 78 atm. yielded 4% gases (and loss), 19.5% b. up to 200° and 16.2% b. 200–300°, 10.3% b. 145–203°, 17.2% b. 203–55°, 20% b. 255–303°, 9.4% b. 303–352°. The fractions b. 145–303° had a higher d. than the corresponding fractions of the original oil. Finally, a mixt. of naphthenes and aromatic hydrocarbons, a Baku machine oil b. 250–90°, heated 12 mins. at 463° under 10 atm. gave 15.6% gases (and losses), 26.3% benzene, b. up to 200°, 25.0% petroleum (200–300°) and 5.1, 11.3, 5.6, 1.3, 1.3% b. 150–80°, 180–200°, 260–80°, 280–300° and 300–15°, resp. Not only the fractions with the same b. p. as the original fractions but even those of lower b. p. have a considerably higher d., indicating that in the cracking there is not only a formation of higher boiling condensation products but also a change in chem. compn., chiefly an increase of aromatic hydrocarbons. The thermodynamics of the cracking process is briefly discussed.

C. A. R.

Reactions of certain olefins of high molecular weight with sulfuric acid, hydrochloric acid and the air. WM. E. MESSER. *Chem. News* 138, 292–3 (1929).—1-*Hexadecene* (I),  $b_{11}$  163°,  $b_2$  123°, m. 4°,  $d_{20}$  0.779, was prepd. by distg. spermaceti under 300–400 mm. pressure. Distn. of Na oleate and NaOEt gave crude 8-*heptadecene* (II) which, purified by fractionation,  $b_{11}$  136°,  $b_{10}$  173°,  $d_{20}$  0.795. *Tertiary alcs.* were prepd. from EtMgBr with the Me ester of com. stearic acid and dehydrated, giving a mixt. b. 152–9°,  $b_{11}$  193–213°, contg. 35%  $\text{C}_{22}\text{H}_{44}$  and 65% of  $\text{C}_{20}\text{H}_{40}$ . Me stearate gave by the above reaction *dimethylheptadecylcarbinol* (III), which was dehydrated with anhyd.  $(\text{CO}_2\text{H})_2$ , giving 2-*methyl-1-nonadecene* (IV),  $b_{11}$  146°,  $b_{10}$  189°, m. 11–2°,  $d_{20}$  0.795,  $n_D^{20}$  1.4504. I and II did not react when shaken with concd. HCl; III gave 95% of 2-*chloro-2-methylnonadecane* (V), m. 19.6–20°, and 5% of IV. With alc. alkali, crude

95% V gave 65% of IV and 35% of III. Olefins were shaken with  $\text{H}_2\text{SO}_4$  and sepd. into 2 layers; no org. matter was found in the  $\text{H}_2\text{SO}_4$  layer; the oil was analyzed for  $\text{SO}_2$ , unsatn., and  $\text{H}_2\text{SO}_4$  upon hydrolysis. Straight-chain compds. (VI) were attacked by 80%  $\text{H}_2\text{SO}_4$  and branched-chain compds. (VII) by 70%; stronger acid had the same effect. After shaking and standing 1 hr., the oil contd. 35–50%  $\text{H}_2\text{SO}_4$ ; VI gave  $\text{SO}_2$  with 95%  $\text{H}_2\text{SO}_4$ ; VII gave much less. The  $\text{SO}_2$  increased upon standing and heating; increasing the quantity of  $\text{H}_2\text{SO}_4$  used for the test increased the  $\text{ROSO}_3\text{H}$  but had no effect upon the  $\text{SO}_2$  value; fuming or 100%  $\text{H}_2\text{SO}_4$  produced  $\text{SO}_2$  and tar even at  $-15^\circ$ ; VI gave more  $\text{ROSO}_3\text{H}$  than did VII. Ba alkylsulfates of I and II were isolated and converted to free acids which readily hydrolyzed to give 2-hexadecanol, m.  $41.5^\circ$ , 8-heptadecanol and 9-heptadecanol, the last 2 as a mixt., m.  $34^\circ$ . IV gave a mixt., m.  $45^\circ$ . IV was most readily oxidized, 0.23 atoms of  $\text{O}_2$  being absorbed at room temp. by a 1-cm. layer in 1450 hrs.; absorption was a linear function of time. All of the olefins were oxidized at  $100^\circ$  and  $156^\circ$ , acids being formed; tars resulted at the higher temp. A. S. CARTER

**Action of alkalis on chloroform.** D. VORLÄNDER AND FRIEDRICH W. GUTHKE *Ber.* 62B, 549–54 (1929).—To explain the remarkably strong reducing power of  $\text{CHCl}_3$  and alkalis on Fehling sol., it has been assumed that, not to mention chlorinated intermediate products ( $\text{CCl}_2$ ,  $\text{CHCl}$ ), activated CO and  $\text{HC(OH)}_2$ , an aldehyde (either as nascent  $\text{HCO}_2\text{H}$  or  $\text{HCHO}$ ) might be a primary decompn. product of the  $\text{CHCl}_3$ . V. and G. have attempted to shed light on this by the use of methone (5,5-dimethylhydroresorcinol) (I), which is a sp. aldehyde reagent. As the result of their expts.  $\text{HCHO}$  is excluded as an intermediate product in the  $\text{CHCl}_3$ -alkali reaction. They obtained, not the  $\text{HCHO}$ , but a *formic acid compd.* (II) of I. Preformed alkali formate in neutral or alk. soln. or the formate ion, however, do not react with I. Similar to the action of  $\text{CHCl}_3$  on Fehling soln. is that of  $\text{CHBr}_3$  (only somewhat more sluggish),  $\text{CHI}_3$  (in boiling alc. alk. soln.),  $\text{CCl}_3\text{CHO}$  and  $\text{CCl}_3\text{CO}_2\text{H}$ . CO or  $\text{CHCl}_3$  and alkali give at room temp. with Fehling soln. the brick-red Cu oxide which according to Moser is formed only in hot Fehling soln. Cold  $\text{NH}_3$ - $\text{AgNO}_3$  is also reduced.  $(\text{CH}_2\text{Cl})_2$ ,  $(\text{CH}_2\text{Br})_2$ ,  $\text{MeCHCl}_2$ ,  $(\text{CHCl}_2)_2$  and  $(\text{CCl}_3)_2$  have no perceptible reducing action.  $\text{CCl}_4$  and alkali give no  $\text{Cu}_2\text{O}$  with Fehling soln.  $\text{HCO}_2\text{H}$  with I gives the same II as was obtained with  $\text{CHCl}_3$ -alkali, although formic esters and alkali do not react with I. Esters of  $\text{HC(OH)}_2$  and alkali react with neither I nor Fehling soln. CO likewise does not react with I or with I and alkali and attempts to activate the CO by ultra-violet illumination, silent elec discharge (in an ozonizer) or heat were unsuccessful. Since I in  $\text{H}_2\text{O}$  or alc. reacts only with aldehydes and not with CO, ketones or  $\text{CO}_2\text{H}$  acids, there might be conceived as an intermediate product, along with  $\text{ClCHO}$ , a hydroxyformaldehyde, an energy isomer of  $\text{HCO}_2\text{H}$ , formed directly from the  $\text{CHCl}_3$  or through chlorinated intermediate products. In such a  $\text{HOCHO}$  the hydroxyl H might not be as strongly dissociated as in  $\text{HCO}_2\text{H}$  and the  $\text{HOCHO}$  might, contrary to  $\text{HCO}_2\text{H}$ , be unusually chem. reactive and capable of existence for a short time in the  $\text{CHCl}_3$ -alkali mixt. In free  $\text{HCO}_2\text{H}$  itself there would

be an equil. between the 2 forms,  $\text{HO}(\dot{\text{C}}:\ddot{\text{O}}):\text{H} \rightleftharpoons \text{H}:\ddot{\text{O}}:(\text{C}:\ddot{\text{O}}):\text{H}$ . Free  $\text{HCO}_2\text{H}$  as a result would have a reducing action in hot aq. soln. but chiefly by virtue of the minute amt. of  $\text{HOCHO}$  in equil. with the real  $\text{HCO}_2\text{H}$ , whereas in solns. of alkali formates the  $\text{HOCHO}$  cannot exist under the influence of the metal and the salts and esters of  $\text{HCO}_2\text{H}$  therefore have no reducing action and do not react with I. II, apparently formed according to the equation  $\text{HOCHO} + 3\text{C}_6\text{H}_{13}\text{O}_2 = 3\text{H}_2\text{O} = \text{C}_{18}\text{H}_{32}\text{O}_6$ , may be considered as a hydrogenated triphenylmethane,  $\text{CH}(\text{C}_6\text{H}_{11}\text{O}_2)_3$ , in which a mol. of  $\text{H}_2\text{O}$  has been eliminated between 2 of the  $\text{C}_6\text{H}_{11}\text{O}_2$  residues; the resulting II, designated *anhydrotri*

can be titrated with Na alcoholate and characterized through monoacyl derivs. and is not easily converted back into its components with boiling alkali. It m. about  $234^\circ$  (cor.) with decompn., is sol. in  $\text{Na}_2\text{CO}_3$ , dil.  $\text{NaOH}$  and  $\text{NH}_4\text{OH}$  and in concd.  $\text{HCl}$  and  $\text{H}_2\text{SO}_4$  with yellow color, insol. in dil.  $\text{HCl}$ , gives a dark green-brown color with  $\text{FeCl}_3$  in alc.; *Na salt*, yellow, decomp.  $255-60^\circ$ ; *acetate*, m.  $153^\circ$ , solidifies cryst.-solid with supercooling, insol. in alkalis, gives no color with  $\text{FeCl}_3$ ; *benzoate*, m.  $258^\circ$  (decompn.). In the prepn. of II from  $\text{CHCl}_3$ -alkali, the  $\text{CHCl}_3$  layer contains an alkali-insol. by-prod-

uct, m. 175–7°, having approx. the compn.  $C_{17}H_{22}O_4$ , easily decompd. into I by hot acids and alkalis. C. A. R.

**Synthesis of higher alcohols from carbon monoxide and hydrogen.** HANS DERSIN. *Chem.-tech. Rundschau* **44**, 310 (1929).—By passing CO and  $H_2$  over the same catalyzers, but at a slower rate than for MeOH, there may be obtained *alcs.* of higher mol. wt. These are contaminated with MeOH, aldehydes, amines and small quantities of liquid hydrocarbons. By suitable variation in the operating conditions formation of higher alcs. is favored. The pat. literature is reviewed. F. PICKERING

**Synthetic production of methanol from carbon monoxide and hydrogen.** HANS DERSIN. *Chem.-tech. Rundschau* **44**, 146–8, 176 8 (1929).—A review of periodical and pat. literature on production and purification of initial materials, app., *catalyzers* and purification of the crude *methanol*. F. PICKERING

**Diethyl ether. I. The products of its autoxidation.** HAROLD KING. *J. Chem. Soc.* **1929**, 738–50.—Ether on storage may change into AcH and peroxides. Clover (C. A. **16**, 1930) concluded that  $EtOCH(OOH)Me$  was formed; Wieland and Winger (C. A. **17**, 2558) suggested that the peroxide was di- $\alpha$ -hydroxyethyl peroxide,  $MeCH(OH)OOCH(OH)Me$ , (I). K. from new detns. (a table is given) finds that the ratio of AcH to peroxides in old ethers is approx. 1:1, in agreement with either theory. That old ethers can fix more AcH, in the ratio 2:1, disproves Clover's constitution for the peroxide, but is consistent with W. and W.'s view that the peroxide is a combination of AcH and  $H_2O_2$ . K., however, from detns. of the partition coeffs. of the peroxides in question between water and ether, concludes that the main peroxide in old ether is  $MeCH(OH)OOH$ . A 2nd more stable peroxide is indicated in old ether by an increase of  $H_2O_2$  in the residue after distn. with acid. This peroxide might be *s*-dihydroxydimethyl peroxide,  $HOCH_2OOCH_2OH$  (II), but no  $HCIO$  could be found in the distillate. K.'s method for detg. peroxides in ether is more rapid than the usual liberation of  $I_2$  from  $KI$ , is accurate, and is applicable in all cases except with II: to 5–10 cc. ether and a few crystals  $MnSO_4$  in 50 cc. approx.  $N H_2SO_4$ , 0.1  $N KMnO_4$  is added until the pink color produced by 2 drops of  $KMnO_4$  has not entirely faded in 10 secs. The peroxides remain behind quant. when old ether is distd. with a column. One part  $H_2O_2$  in 400,000 parts ether (in the absence of org. peroxides and AcH) may be detected by acid  $K_2Cr_2O_7$  (faint blue color) or by Jorissen's vanadic acid reagent (Baskerville and Hamor, C. A. **5**, 2303) (brownish orange color). The AcH in ether is estd. by Ripper's method (*Monatsh.* **21**, 1079), by acidifying and distg. into  $NaHSO_4$ . AcOH (Richardson and Fortey, *Proc. Chem. Soc.* **1896**, 165) and  $HCO_2H$  are also present in old ether. I is prepd. as a clear sirup by extg. Merck's  $H_2O_2$  with dry ether, adding 2 mols. AcH for each mol.  $H_2O_2$  and evapg. rapidly in a vacuum. Cryst. II is prepd. from formalin and  $H_2O_2$  in water. I and II do not give blue colors with alc. benzidine or guaiacum until peroxidase is added. Like  $HCHO$  and  $H_2O_2$  together (Woker, C. A. **8**, 3663; Wieland and Winger, *l. c.*), a fresh aq. soln. of 2 AcH and 1  $H_2O_2$  gives the benzidine test, but not after 2–3 days. The color is thought to be due to the formation of an intermediate peroxide, as  $MeCH(OH)OOH$ . The peroxide from old ether also gives the benzidine test. JANET D. SCOTT

**Hydrogenation and decomposition of silico-organic compounds at high temperature and pressure.** V. IPAT'EV AND B. N. DOLGOV. *Ber.* **62B**, 1220–6 (1929).—This is the first of a series on the stability of the group Si-C and Si-O-Si. Tetraethylsilane (I) at 350° under a  $H_2$  pressure splits off ethane, giving hexaethyldisilane (II) and other products. Triethylphenylsilane gives benzene and II. It also rearranges to give I and diethyldiphenylsilane. Tetraphenylsilane is stable up to 490°, where it yields a product probably of a highly condensed nature. V. F. HARRINGTON

**Action of potassium cyanide on chloroaldehydes.** FREDERICK D. CHATTAWAY AND HARRY IRVING. *J. Chem. Soc.* **1929**, 1038–48.—The action of KCN upon  $Cl_2CCHO$  in MeOH, EtOH, PrOH and allyl alc. gives, resp.,  $Cl_2CHCO_2Me$  (84%),  $Cl_2CHCO_2Et$  (88%), *Pr* *dichloroacetate*, b. 176° (70%) and the *allyl ester*, b. 175.5° (64%).  $Cl_2CHCHO$ , EtOH and KCN in EtOH give 58%  $Cl_2CHCO_2Et$ ,  $Cl_2CHCHO$  and KCN in EtOH or  $H_2O$  give 10% of AcOEt.  $MeCHClCCl_2CH(OH)_2$  and KCN in EtOH give, if the reaction is not moderated,  $MeCH:CClCO_2Et$ ; if the temp. is not allowed to rise above 15°, there also results  $MeCHClCHClCO_2Et$  and some *butylchloral cyanohydrin* (I), m. 101–2°.  $MeCHClCHClCO_2Et$  loses HCl readily, giving  $MeCH:CClCO_2Et$ ,  $MeCHCl$

EtOH give 85% of  $MeCH:CClCO_2Et$ . In  $H_2O$  the reaction products of KCN and  $MeCHClCCl_2CH(OH)_2$  are I and  $MeCH:CClCO_2H$ .  $CCl_2CH(OH)NH_2$  and KCN

give 92% of  $\text{Cl}_3\text{CHCONH}_2$ .  $\text{MeCHClCCl}_2\text{CH(OH)NH}_2$  and KCN give 93% of  $\text{MeCH}_2\text{CClCONH}_2$ . KCN has little or no action on dichloroacetal.  $\text{Cl}_3\text{CCH(OAc)}$ , in EtOH give 80% of  $\text{Cl}_3\text{CHCO}_2\text{Et}$ ; in MeOH 76% of  $\text{Cl}_3\text{CHCO}_2\text{Me}$ .  $\text{MeCHClCCl}_2\text{CH(OH)}_2$  and KCN in  $\text{C}_6\text{H}_6$  probably give 6-keto-2,4,7-tris[ $\alpha,\alpha,\beta$ -trichloropropyl]cyclo-2,4,6,7-tetramethylene-1,3,5-dioxamine, m. 99.5–100.5°. 6-Nitro-2,4-bis[trichloromethyl]-1,3-benzodioxin and KCN in EtOH give 6-nitro-2 (or 4)-trichloromethyl-4 (or 2)-dichloromethylene-1,3-benzodioxin, m. 136.5°. The mechanism of these reactions is discussed.

C. J. WEST

Products of the action of chlorosulfonic acid on propionyl chloride at room temperature. M. KRAJČINOVIČ. *Ber.* 62B, 579–81(1929); cf. *C. A.* 21, 224.—From 50 g.  $\text{EtCOCl}$  treated in the course of 3–4 hrs. with 50 g.  $\text{ClSO}_3\text{H}$ , allowed to stand 5–10 days at room temp. (the evolution of HCl becomes distinctly perceptible only on the 2nd day) and then poured into cold  $\text{H}_2\text{O}$  is obtained a pitch-like mass from which  $\text{Et}_2\text{O}$  exts.  $\alpha'$ -ethyl- $\beta,\beta'$ -dimethylpyrone,  $\text{EtC:CMc.CO.CHMe.CO.O}$  (I), m. 151°, and

the residue remaining from the  $\text{Et}_2\text{O}$  extn. yields  $\text{MeCH(SO}_3\text{H)CO}_2\text{H}$ . The formation of I is explained as follows: The  $\text{ClSO}_3\text{H}$  combines with the  $\text{EtCOCl}$  to form  $\text{EtCO}_2\text{SO}_2\text{CHMeCO}_2\text{SO}_2\text{CHMeCOCl}$ ; the  $\text{SO}_3$  groups are then split off and the resulting  $\text{EtCOCHMeCOCHMeCOCl}$  partially enolizes at the  $\delta$ -C atom and the ring in I is closed by elimination of HCl.

C. A. R.

Volatility and structure of the azides and aliphatic diazo compounds. NEVIL V. SMDGWICK. *J. Chem. Soc.* 1929, 1108–10.—Published data on the b. ps. of azides and aliphatic diazo compds. are recorded. The b. ps. of the azides lie near those of the bromides or between these and the iodides; the b. ps. of the diazo compds. lie very near those of the chlorides; those of the  $\text{NO}_2$  compds. are always much higher. These results seem to indicate that the ring formulas should be retained for both of these classes of compds.

C. J. WEST

Electronic conception in organic chemistry. II. An interpretation of the  $\alpha$  glycols. MASAO MIGITA. *Bull. Chem. Soc. Japan* 4, 57–65(1929); cf. *Ibid* 3, 308–16 (1928).—Dehydration of these glycols may proceed in 3 ways: (1) the semihydrobenzoin rearrangement,  $\text{HORR'CCHR''OH} \rightarrow \text{RR'CCHR''O} \rightarrow \text{RR'R''CCHO}$ ; (2) the vinyl dehydration,  $\text{HORR'CCHR''OH} \rightarrow \text{RR'C:CR''OH} \rightarrow \text{RR'HCCOR''}$ ; or (3) the semipinacolin rearrangement,  $\text{HORR'CCHR''OH} \rightarrow \text{RR'C(O)CHR''} \rightarrow \text{RCOCHR'R''}$ . With dil.  $\text{H}_2\text{SO}_4$ : Owing to the highly positive nature of the H, nearly all these glycols have negatively polarized tertiary hydroxyls, therefore, if the dehydration is catalytic, as previously discussed, it must be this group that is removed with either of the hydrogens on the secondary C; which H is removed is dependent on the substituting groups of that C, and hence the reaction goes according to (1) or (2). If the radicals on the tertiary C are strongly pos. and those on the secondary strongly neg., the secondary HO is induced negatively and hence removed. The reaction goes according to (3). With concd. acid the reaction is one of substitution, hence these influences are interfered with by the fact that the secondary HO is substituted more easily than the tertiary, hence (2) occurs when the tertiary HO is polarized negatively. With a negative secondary HO or in glycols without marked polarity (3) occurs. In the last case it is to be noticed that the secondary C is made highly pos. by the presence of the  $\text{SO}_3\text{H}$ ; hence, if the substituents on the other C are different, the more neg. one will migrate. The work in 26 articles has been examd. and found to agree with this conception.

V. F. HARRINGTON

Catalytic reduction of the dioximes—preparation of 2,3-diaminobutane. J. FREJKA AND MILLE. L. ZAHLOVA. *Collection Czechoslov. Chem. Comm.* 1, 173–87(1929).—Pure 2,3-diaminobutane is readily prepd. by the catalytic reduction of dimethylglyoxime in AcOH in the presence of Pt black. The free AcOH in the resultant soln. is removed by vacuum distn. Upon adding KOH, the residue seps. into 2 layers, the upper layer contg. the amine. Upon fractional distn., pure 2,3-diaminobutane is obtained, mainly in the form of its hydrate,  $\text{C}_4\text{H}_9(\text{NH}_2)_2 \cdot \text{H}_2\text{O}$ . Yields of 50% are reported. Upon fractional distn., the monohydrate and possibly the hemihydrate are obtained. The consts. of the former are:  $b_m$  56–60°,  $d_4^{20}$  0.90024,  $n_D^{20}$  1.44496. Upon dehydration by metallic Na, the anhyd. amine was obtained as a clear liquid, fuming in moist air and absorbing moisture and  $\text{CO}_2$  with avidity. It is sol. in  $\text{H}_2\text{O}$  and org. solvents, and has a disagreeable odor suggesting  $\text{NH}_3$ . The consts. are:  $b_m$  60–4°,  $d_4^{20}$  0.86011,  $n_D^{20}$  1.44416. The following deriva. were prepd.: *HCl salt*,  $\text{C}_4\text{H}_9(\text{NH}_2)_2 \cdot 2\text{HCl}$ , needle-like crystals, sol. in  $\text{H}_2\text{O}$ , slightly sol. in EtOH, insol. in  $\text{Et}_2\text{O}$ ; *HBr salt*,  $\text{C}_4\text{H}_9(\text{NH}_2)_2 \cdot 2\text{HBr}$ , needles, slightly sol. in EtOH, sol. in  $\text{H}_2\text{O}$ , insol. in  $\text{Et}_2\text{O}$ ; *sulfate*,  $\text{C}_4\text{H}_9(\text{NH}_2)_2 \cdot \text{H}_2\text{SO}_4$ , needles; *chromate*,

$C_4H_8(NH_2)_2$ ,  $H_2CrO_4$ , yellow powder; *chloraurate*,  $C_4H_8(NH_2)_2 \cdot 2HAuCl_4$ ; *chloroplatinate*,  $C_4H_8(NH_2)_2 \cdot H_2PtCl_6$ , orange-yellow, sol. in  $H_2O$ , slightly sol. in  $EtOH$ ; *oxalates*,  $C_4H_8(NH_2)_2 \cdot H_2C_2O_4 \cdot H_2O$ , white needles, and  $C_4H_8(NH_2)_2 \cdot H_2C_2O_4$ ; *succinate*,  $C_4H_8(NH_2)_2 \cdot H_2C_4H_4O_6$ , small white needles; *picrate*,  $C_4H_8(NH_2)_2 \cdot 2C_6H_3(NO_2)_3OH$ ; *picrolonate*,  $C_4H_8(NH_2)_2 \cdot 2C_{10}H_8N_4O_8$ ; *acetate*,  $C_8H_{10}N_2O_2$ , silky white needles; *phenyl isocyanate*,  $C_8H_8N_2N_2O_2$ , voluminous white powder; *Et acetate deriv.*,  $C_{16}H_{28}N_2O_4$ , white powder, m.  $59^\circ$ .

J. H. REEDY

**Polymethylene acid alcohols ( $\omega$ -hydroxyaliphatic acids) containing 8 to 21 carbon atoms.** P. CHUIT and J. HAUSSE. *Helv. Chim. Acta* 12, 463-92 (1929).—Several sym. acid alcs. or their derivs. have been isolated from waxes derived from conifers. In order to augment the present knowledge of this class of acids all the hydroxy fatty acids contg. 8-21 C atoms have been synthesized and their properties studied. Of these acids the  $C_9$ ,  $C_{10}$ ,  $C_{11}$ ,  $C_{13}$ ,  $C_{16}$  and  $C_{17}$  compds. have been prepd. and most of these characterized. The  $C_8$  acid was prepd. by reduction of the ester,  $HO_2C(CH_2)_6CO_2Me$  (I),  $b_1$  146-50°,  $d_{20}$  1.047, crystn. p. about 10°. This ester was transformed into the K salt, reduced with Na and alc., acetylated and dissolved in benzene to sep. it from suberic acid. From 100 g. of I, 15 g. of the Ac compd.,  $HO_2C(CH_2)_6CH_2OAc$  (II),  $b_1$  155-8°, m. 9-10°,  $d_{20}$  1.042, was obtained. Sapon. of II gives the HO acid,  $HO_2C(CH_2)_6CH_2OH$  (III), m. 58°. *Me ester* (9 g. from 12 g. of acid),  $b_1$  137-8°,  $d_{20}$  0.992. The Br deriv.,  $HO_2C(CH_2)_6CH_2Br$ ,  $b_1$  147-50°, m. 38.5-9.0°, was prepd. from III by treatment with 50% HBr. Several methods were used in the prepn. of the  $C_9$  acid. (a). The K salt of the ester  $HO_2C(CH_2)_7CO_2Me$  (IV) was reduced in a manner similar to that used for the prepn. of III. From 250 g. of the ester 85 g. of the Ac compd.,  $HO_2C(CH_2)_7CH_2OAc$  (V),  $b_1$  192-3°, crystn. p. 1°,  $d_{20}$  1.025, was obtained. The HO acid,  $HO_2C(CH_2)_7CH_2OH$  (VI), m. 51-1.5°, was formed upon sapon. of V. The yield of VI was 31.5% calcd. on IV. (b). The di-Me azelate,  $(CH_2)_7(CO_2Me)_2$  (VII), was reduced as in (a). From 200 g. there was obtained 20 g. of V and 8% of VI, besides 73% of the corresponding glycol (VIII), m. 45°. (c). The bromohydrin of VIII,  $CH_2Br(CH_2)_7CH_2OH$  (IX),  $b_1$  125-6° (without decompn.), m. 33.5°, (20 g.) was oxidized with  $K_2Cr_2O_7$  and  $H_2SO_4$ . One portion (11 g.) of the oxidation products dissolves in  $Na_2CO_3$  soln. and consists of the Br acid,  $CH_2Br(CH_2)_7CO_2H$  (X),  $b_1$  160-1°, m. 36-6.5°; the other portion (9 g.) contains the ester,  $CH_2Br(CH_2)_7CH_2O_2C(CH_2)_7CH_2Br$  (XI),  $b_1$  228-32°, m. 5°,  $d_{15}$  1.237, formed by the condensation of IX and X. The yields of X and XI were 47% and 34%, resp. Heating XI with KOAc at 200° yields the corresponding diacetate (XII),  $b_1$  222-3°,  $d_{20}$  0.988. Upon sapon. of XI, VI was obtained in theoretical yield. The heat treatment of X (25 g.) with KOAc led to the formation of 12 g. of impure V and 8 g. of the acetylated etholide,  $AcOCH_2(CH_2)_7CO_2CH_2(CH_2)_7CO_2H$  (XIII),  $b_1$  250-60°, m. 40°. This compd. is a condensation product of V and X. It may also be obtained by the heating of V. The sapon. of XIII or the heating of VI yields a simple etholide of VI,  $CH_2(OH)(CH_2)_7CO_2CH_2(CH_2)_7CO_2H$  (XIV), m. 60-1°, which, when heated at 200° for 1 hr., also combines with itself to form a double etholide,  $HO_2C(CH_2)_7CH_2O_2C(CH_2)_7CH_2O_2C(CH_2)_7CH_2O_2C(CH_2)_7CH_2OH$  (XV), m. 71-2°. (d). Azelaic acid monoacetate (XVI),  $b_1$  159-61°,  $d_{20}$  0.955, (60 g. from the acetylation of 100 g. of VIII with  $Ac_2O$  and NaOAc), when oxidized, yields impure V. This was transformed into the *Me ester* of VI,  $b_1$  147-50°,  $d_{20}$  0.978 and then sapon. to give VI. Among the oxidation products XII was also present. The compd.  $BrCH_2(CH_2)_8CO_2H$  (XVII),  $b_1$  163-5°, m. 42-2.5°, was prepd. from the corresponding HO acid (XVIII) which had been previously characterized by its treatment with 50% HBr in HOAc. The *Me ester* of XVIII,  $b_1$  160-5° (27 g.), when heated to 220-30°, yields 6 g. of the etholide,  $CH_2(OH)(CH_2)_8CO_2CH_2(CH_2)_8CO_2H$  (XIX), m. 56-6.5°. From 55 g. of the acetylated acid,  $HO_2C(CH_2)_8CH_2OAc$  (XX), 110 g. of MeOH and 10 g. of  $H_2SO_4$ , 27 g. of the Me ester and 15 g. of the *Me etholide* were obtained. Heating of XIX led to the formation of many products, one of which was isolated and had the formula  $C_{30}H_{50}O_{13}$ , m. 72.5-3.0°. The analysis indicated the condensation of 6 mols. of XVIII, although titration signified that 7 mols. were condensed. The acid,  $CH_2(OH)(CH_2)_9CO_2H$  (XXI), already known, was prepd. in 2 ways. (a). The nitrile,  $CH_2(OH)(CH_2)_9CN$ ,  $b_1$  186-7°, m. 12-3°,  $d_{20}$  0.910, was prepd. from XVII (23 g. from 30 g. of XVII and 9 g. of KCN) and when sapon. gave XXI. (b). The Na deriv. from 45 g. of  $CH_2(CO_2Me)_2$  was allowed to react with 70 g. of IX. The resulting ester was sapon., acidified, acetylated and decompd. by heating at 150°. A yield of 50 g. of the acetylated acid,  $CH_2(OAc)(CH_2)_9CO_2H$  (XXII),  $b_1$  184-5°, m. 34°, was thus obtained. Sapon. of XXII resulted in 40 g. of XXI. *Me ester*,  $b_1$  168-9°, m. 27-7.5° (7 g.) from 10 g. of XXI. The Br-acid,  $CH_2Br(CH_2)_9CO_2H$ ,  $b_1$  173-4°, m. 51° (6 g.), was obtained from 5 g. of XXI by treatment with HBr in HOAc as usual. Sabinic acid,  $HO_2C(CH_2)_{10}CH_2OH$  (XXIII), was prepd. in 2 ways. (a).

$\text{CHNa}(\text{CO}_2\text{Me})_2$  was condensed with XVII as in (b) for the prepn. of XXI. (b). The ester,  $\Delta^{12}$ -tridecenyl acetate (55 g.), was oxidized with  $\text{O}_3$  with the formation of 19 g. of *acetylsabinic acid*,  $b_{0.5}$  174–6°, m. 45°. When this was sapond, XXIII was obtained. Besides the acid the oxidation products contained the aldehyde,  $\text{AcOCH}_2(\text{CH}_2)_{10}\text{CHO}$ ,  $b_{0.5}$  143–5°, m. 8–9°,  $d_{15}$  0.9436; *semicarbazone*, m. 85–6°. Reduction of 16 g. of XXIII gave 5.2 g. of the corresponding glycol (XXIV),  $b_s$  184–6°, m. 79–9.5°. The *Me ester* of XXIII m. 34–4.5°. The *acetyl Me ester*, prepd. from the *Me ester* with  $\text{AcCl}$  and  $\text{C}_6\text{H}_5\text{N}$ ,  $b_{0.5}$  150–3°, m. 15°. The *Br acid*, m. 52–2.2°. Reduction of the ester  $(\text{CH}_2)_{11}(\text{CO}_2\text{Me})_2$  (60 g.) as in (b) for the prepn. of VI yielded the acetylated acid,  $\text{CH}_2(\text{OAc})(\text{CH}_2)_{11}\text{CO}_2\text{H}$  (XXV),  $b_1$  202–3°, m. 49–9.2°. Sapon. led to the formation of the acid,  $\text{CH}_2(\text{OH})(\text{CH}_2)_{11}\text{CO}_2\text{H}$  (XXVI), m. 79–9.5°. *Me ester*,  $b_{10}$  192–3°, m. 44.5°. The *Br acid* was prepd. in 2 ways. (a). Treatment of 80 g. of XXVI with  $\text{HBr}$  in  $\text{HOAc}$  gave 95 g. of the *Br acid* (XXVII),  $b_{1.5}$  190–2°, m. 59–9.2°. (b). The bromohydrin,  $\text{CH}_2\text{Br}(\text{CH}_2)_{11}\text{CH}_2\text{OH}$  (XXVII), m. 59°, was formed by the bromination of the corresponding glycol. Oxidation of XXVII yields XXVIII besides the product of condensation of XXVII and XXVIII. The di-*Br ester*,  $\text{Br}(\text{CH}_2)_{12}\text{CO}_2(\text{CH}_2)_{12}\text{Br}$ , m. 38–9°. The acid,  $\text{CH}_2(\text{OH})(\text{CH}_2)_{12}\text{CO}_2\text{H}$  (XXIX) was prepd. in 3 ways. (a). In the reduction of the di-*Me ester* of the acid  $(\text{CH}_2)_{12}(\text{CO}_2\text{H})_2$  (XXX) a wax was obtained which consisted of a condensation product of XXIX and XXX, m. 75°. This wax was sapond. and then treated as in the prepn. of III. The *Ac compd.*,  $\text{CH}_2(\text{OAc})(\text{CH}_2)_{12}\text{CO}_2\text{H}$  (XXXI),  $b_1$  215°, m. 54–4.5°, was so obtained. Sapon. gave XXIX. (b).  $\text{CHNa}(\text{CO}_2\text{Me})_2$  was condensed with the bromohydrin,  $\text{CH}_2\text{Br}(\text{CH}_2)_{12}\text{CH}_2\text{OH}$  (XXXII), and the acid was purified by sapon. of the *Me ester*,  $b_{10}$  196–8°, m. 47°. (c). The compd. XXVIII is transformed into the nitrile,  $\text{OH}(\text{CH}_2)_{12}\text{CN}$ ,  $b_1$  205°, m. 53–3.4° (7 g. from 10 g. of XXVIII). By sapon. and acidification XXIX was obtained. The *Br acid*, m. 61.8–2.0°. A yield of 12% of the acid,  $\text{CH}_2(\text{OH})(\text{CH}_2)_{13}\text{CO}_2\text{H}$  (XXXIII), was obtained by reduction of  $(\text{CH}_2)_{13}(\text{CO}_2\text{Me})_2$ . Condensation of XXVIII with malonic ester also yielded XXXIII after the sapon. of the *Ac deriv.*,  $b_2$  219–21°, m. 59.4–9.6°. *Me ester*,  $b_2$  180–2°, m. 52–2.5°. The *Br acid*, m. 65–2–5.5°. Juniperic acid,  $\text{CH}_2(\text{OH})(\text{CH}_2)_{14}\text{CO}_2\text{H}$  (XXXIV), was prepd. in 2 ways. (a). The ester,  $(\text{CH}_2)_{14}(\text{CO}_2\text{Me})_2$  was reduced and 11.5% of the *Ac compd.*,  $\text{CH}_2(\text{OAc})(\text{CH}_2)_{14}\text{CO}_2\text{H}$  (XXXV), was obtained. Sapon. gave XXXIV. (b). The glycol,  $(\text{CH}_2)_{14}(\text{CH}_2\text{OH})_2$  (390 g.), was heated with 193 g. of  $\text{Ac}_2\text{O}$  and 20 g. of  $\text{NaOAc}$  and yielded 255 g. of the *diacetate*, m. 47°,  $b_{1.5}$  193–4°, and 145 g. of the *mono acetate* (XXXVI),  $b_s$  217–8°,  $b_1$  193–5°, m. 54–4.5°, besides 40 g. of unchanged material. Oxidation of 100 g. of XXXVI with  $\text{CrO}_3$  yielded 75 g. of XXXV, m. 62°, and 25 g. of the condensation product of XXXV and XXXVI. Sapon. of 120 g. of XXXV yielded 95 g. of XXXIV. The *Me ester* (6 g. from 8 g. of XXXIV)  $b_2$  194–6°, m. 55–5.5°. The *Br acid* (75 g. from 75 g. of XXXIV)  $b_1$  214–7°, m. 70–0.5°. The synthesized XXXIV was found to be identical with the natural product derived from the wax obtained from pine needles of the fir in a yield of 0.17% based on the dry needles. The etholide,  $\text{C}_{44}\text{H}_{122}\text{O}_6$ , m. 87–5–8.0°, was obtained by heating XXXIV at 125°. The formula was confirmed by titration. When dissolved in benzene it crystallizes with benzene of crystn. The acid,  $(\text{CH}_2)_{15}(\text{OH})\text{CO}_2\text{H}$ , m. 87.5–8.0°, was obtained by sapon. of its *Ac deriv.*,  $b_1$  223–5°, m. 67.6–8.0°, a yield of 11% of which was formed by the reduction of  $(\text{CH}_2)_{15}(\text{CO}_2\text{Me})_2$ . *Me ester*,  $b_3$  210°, m. 58.6–9.0°. The *Br acid*  $b_1$  219–20°, m. 70.5–1.0°. In a similar manner, the  $\text{C}_{18}$ ,  $\text{C}_{19}$ ,  $\text{C}_{20}$  and  $\text{C}_{21}$  acids were prepd. from the corresponding dibasic acid esters. The  $\text{C}_{18}$  acid, m. 96.6–7.2°; *Ac deriv.* (yield 15 g. from 115 g. of ester),  $b_1$  228–31°, m. 70–0.5°; *Me ester*, m. 61.5–2.0°; *Br acid*,  $b_4$  240–1°, m. 75.2–5.8°. The  $\text{C}_{19}$  acid (yield 10%), m. 91–1.5°; *Ac deriv.*,  $b_{2.5}$  225–9°, m. 70–0.2°; *Me ester*, m. 65.6–6.0°; *Br acid*  $b_{2.5}$  225–8°, m. 73–4°. The  $\text{C}_{20}$  acid (yield 8%), m. 97.4–7.8°; *Ac deriv.*,  $b_3$  235–40°, m. 77°; *Me ester*, m. 68–8.5°; *Br acid*,  $b_3$  245–7°, m. 77–8°. The  $\text{C}_{21}$  acid (yield 16%), m. 92.5–3.0°; *Ac deriv.*,  $b_3$  239–42°, m. 73.8–4.2°; *Me ester*, m. 70–1°. *Br acid*, m. 75–6°. When the m. ps. of the HO acids were plotted against the no. of C atoms in the mol., 2 curves were obtained, according to whether the mols. had an even or odd no. of C atoms. The same was true of the *Ac derivs.*, *Me esters* and *Br acids*.

**Amino acid anhydrides.** III. Curtius and Goebel's glycine anhydride silver compound. TEI-ICHI ASAHINA. *Bull. Chem. Soc. Japan* 4, 75–7 (1929); cf. C. A. 23, 819.— $\text{Ag}_2\text{O}$  with glycine anhydride and a little  $\text{NH}_3$  turns white. The product is sol in  $\text{HNO}_3$  and  $\text{NH}_4\text{OH}$  and explodes on heating. It is probably identical with C. and G.'s compd.

V. F. HARRINGTON

**Reactions of nitrosulfonyl chlorides.** I. Reaction of hydrazine hydrate with *o*-nitrosulfonyl chlorides. ARTHUR T. DANN and WM. DAVIES. *J. Chem. Soc.* 1929, 1050–5.—2,4,5- $\text{ClMe}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{SO}_2\text{Cl}$  and  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$  in  $\text{C}_6\text{H}_5\text{-EtOH}$ , on warming to

40°, evolve N and give over 90% of 2-chloro-5-nitro-*p*-toluenesulfonic acid (I), very pale yellow, m. 131.5°; heating with  $C_6H_5N$  for 50 hrs. gives 77% of 2,5-Cl(O<sub>2</sub>N) $C_6H_4$ Me; MeOH-MeI give 50% of 2-chloro-5-nitro-*p*-tolyl Me sulfone, m. 145-6°. If the above reaction is carried out in a freezing mixt., there results 98% of 2-chloro-5-nitro-*p*-toluenesulfonehydrazide (II), m. 110-3° (decompn.); this decomp. in the presence of hot aq.  $N_2H_4$  or dil. HCl to form I and the theoretical quantity of N; in hot EtOH II reacts with *o*-HOC<sub>6</sub>H<sub>4</sub>CHO or PhCH:CHCHO to form the azines, although there is evidence of the formation of sulfonehydrazones. In warm PhOMe, PhCH:CHCHO and II give cinnamaldehyde 2-chloro-5-nitro-*p*-toluenehydrazone, dark red, m. 95°. The formation of this hydrazone, the fact that II cannot be obtained pure from MeOH rich in Me<sub>2</sub>CO and the reduction of Fehling's soln. in the cold all indicate that the constitution of II is normal. *o*-Nitrobenzenesulfonehydrazide, m. 101° (decompn.), results in 82% yield but is relatively unstable. 6-Chloro-4-nitro-*o*-toluene- and 2-chloro-6-nitro-*p*-toluenesulfonehydrazides, m. 127° and 125°, resp. *o*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>COCl and  $N_2H_4 \cdot H_2O$  give the hydrazide, and also *N,N'*-di-*o*-nitrobenzoylhydrazine, m. 298°. Benzaldehyde *p*-nitrobenzoylhydrazone, pale yellow, m. 259°; its formation in EtOH is a delicate test for BzII. *N,N'*-Di-*p*-nitrobenzoylhydrazine, pale yellow, m. 291°; it forms a very sparingly sol. scarlet salt. C. J. WEST

**Preparation of *d*-gluconic acid.** H. KILIANI. *Ber.* 62B, 588-92(1929).—Two features of K.'s method for prep. *d*-gluconic acid (I) (oxidation with Br at room temp.) have been found undesirable by a no. of workers: the use of too large an excess of Br and of the "expensive" Ag<sub>2</sub>O to remove the halogen. The large Br excess is used because liquid Br acts much more powerfully and rapidly than Br dissolved in HBr. As to the use of Ag<sub>2</sub>O, while the necessary initial outlay for AgNO<sub>3</sub> is considerable, it can be regenerated at a minimal cost from the Ag halide ppts. PbCO<sub>3</sub> was recommended at one time instead of Ag<sub>2</sub>O but the pptn. of the halogen is always incomplete and it is not at all easy to procure PbCO<sub>3</sub> entirely free of alkali. The method has been improved in some respects; if the glucose soln. which has been treated with Br is shaken very often and at times continuously, the liquid Br disappears in 2.5-3 hrs. (instead of 30-36 hrs.), and instead of using H<sub>2</sub>S, the dissolved Ag is much better removed by cautious addn. of dil. HCl with vigorous shaking; the incomplete crystn. of PbBr<sub>2</sub> from the concd. soln. after complete satn. with PbCO<sub>3</sub> is not due to the formation of a "difficultly sol. double salt" with the gluconate, but to a mutual soly. influence. Being in need of a large amt. of I, K. has worked out a new method of prepn. Boiling with CaCO<sub>3</sub> after the Br treatment and adding alc. to ppt. the Ca gluconate while the CaBr<sub>2</sub> remains in soln. works only with small quantities, for from concd. solns. alc. ppts. the Ca salt only in the form of a thick magma of amorphous pellets which, when filtered, eagerly absorb moisture and deliquesce, and with more dil. solns. an immoderately large amt. of 95% alc. is necessary for adequate pptn. BaBr<sub>2</sub> of itself is difficultly sol. even in 50% alc. but under certain definite conditions (which are described in detail) there can be obtained with BaCO<sub>3</sub> around 65% of quite pure Ba gluconate (contg. only traces of bromide and at most only faintly colored). The Ba gluconate and bromide afford an excellent example of the mutual soly. influence mentioned above; either salt alone crysts. with great ease and cannot be called easily sol. in H<sub>2</sub>O, but in mixts. of the 2 both of these properties disappear. *Addendum.*—In the paper on the use of (CO<sub>2</sub>H)<sub>2</sub> for detg. Ba in salts of org. acids (C. A. 22, 3139) K. stated that the tendency to the formation of an acid salt is practically nil, but he has since found that 50% alc. slowly removes free (CO<sub>2</sub>H)<sub>2</sub> from the crystd. Ba salt. The proposed method, however, loses none of its practical value if the ppt., nearly purified by washing with 50% alc., is converted into the carbonate by gentle ignition. C. A. R.

**Dioximes.** LI. G. PONZIO AND M. MILONE. *Gazz. chim. ital.* 58, 844-53(1928); cf. P., C. A. 22, 4120; 23, 375.—It is known that the formation of solid solns., with resulting abnormalities in the detn. of the mol. wt. of many compds. by cryoscopic methods, is due to the similarity of the mol. structure of the solute and solvent. This fact suggested that it might be possible to verify the structures of the 2 peroxides formed by the dehydrogenation of MeC(:NOH)C(:NOH)Ar compds. and which were assigned the formulas:  $\text{MeC:N}(\text{:O})\text{O:N:CAr}$  (I) and  $\text{MeC:N.O.O.N:CAr}$ , resp. Only I

should form solid solns. with  $\text{MeC:N.O.N:CAr}$  (III) compds. because of the presence of the group  $\text{—C:N.O.N:C—}$  common to both. Expts. confirmed this prediction, I representing the peroxide which melts at the higher temp. This also precludes the

possibility of the structure  $\text{O.N.CMe:CAr.N.O}$ , which is that proposed by Green and Rowe for *o*-quinone dioxime peroxides (cf. *C. A.* 7, 3119; 8, 1412). Compds. of the II type do not form solid solns. with those of the III type so that the structure;  $\text{MeC:N.O.N(:O):CAr}$  is excluded.  $\text{MeC:N(:O).O.N:CPh}$  (IV),  $\text{MeC:N(:O).O.N:CC}_6\text{H}_4\text{OMe-}p$  (V),  $\text{MeC:N.O.O.N:CPh}$  (VI) and  $\text{MeC:N.O.O.N:CC}_6\text{H}_4\text{OMe-}p$  (VII) show normal mol. wts. in AcOH,  $\text{C}_6\text{H}_6$  and PhOH, whereas IV, V and  $\text{MeC:N(:O).O.N:CC}_6\text{H}_4\text{Br-}p$  show in  $\text{MeC:N.O.N:CC}_6\text{H}_4\text{OMe-}p$  (VIII) mol. wts. higher than the theoretical ones. VI and  $\text{MeC:N.O.O.N:CC}_6\text{H}_4\text{Br-}p$  show in VIII mol. wts. above their theoretical ones. In VI and in VII, VIII shows a normal mol. wt. In IV and in V, VIII shows a mol. wt. above the theoretical. The cryoscopic of  $\text{MeC:N.O.N:CPh}$  could not be detd. because of its low f. p. The consts. of Br and  $\text{NO}_2$  derivs. of V and VII in  $\text{MeC:N.O.N:CC}_6\text{H}_3(\text{OMe})\text{Br}$  (IX) and in  $\text{MeC:N.O.N:CC}_6\text{H}_3(\text{OMe})\text{NO}_2$  (X) were then detd. In VIII,  $\text{MeC:N(:O).O.N:CC}_6\text{H}_3(\text{OMe})\text{Br}$  (XI) and  $\text{MeC:N(:O).O.N:CC}_6\text{H}_3(\text{OMe})\text{NO}_2$  (XII) show mol. wts. above the theoretical ones.

In VIII,  $\text{MeC:N.O.O.N:CC}_6\text{H}_3(\text{OMe})\text{Br}$  (XIII) and  $\text{MeC:N.O.O.N:CC}_6\text{H}_3(\text{OMe})\text{NO}_2$  (XIV) show normal mol. wts. XI in IX and XII in X show normal mol. wts. In IX, XIII does not show any lowering of the f. p., and the same is true of XIV in X. These facts establish the constitutions of XI, XII, XIII and XIV, because only XI and XII form solid solns. with VIII and therefore only XI and XII have similar structures to that of VIII. An Eyckmann depressimeter which permitted cstns. to  $0.005^\circ$  was used. Particular care was taken in the purification of VIII, and instead of prepg. it by the method of Boeris (*Gazz. chim. ital.* 23, ii, 186(1893)), furoxan (10 g.) was heated for 24 hrs. on a boiling water bath with glacial AcOH (50 cc.),  $\text{SnCl}_2$  (20 g.) and concd. HCl (50 cc.), dild. with water, treated with  $\text{NaOEt}$  and steam-distd., which gave a product m.  $65.6^\circ$ .

C. C. DAVIS

***d*-Glucuronic acid.** II. FELIX EHRLICH AND KURT REHORST. *Ber.* 62B, 628-34 (1929); cf. *C. A.* 20, 740.—It was shown in the first paper that free *d*-glucuronic acid (I) can be obtained readily and in good yield in cryst. form by cautiously decomp. mentholglucuronic acid (II) with  $\text{H}_2\text{SO}_4$  on the  $\text{H}_2\text{O}$  bath and purifying it through the Ba salt. Lactone formation is avoided if, after the cleavage with  $\text{H}_2\text{SO}_4$ , enough Ba is added not only to ppt. the  $\text{H}_2\text{SO}_4$ , but also to form the salt of I and the I is liberated from this salt at a low temp. with the calcd. amt. of  $\text{H}_2\text{SO}_4$ . In the method of prepn. as originally given, difficulties in the purification sometimes result from the fact that  $(\text{NH}_4)_2\text{SO}_4$  dissolves readily in the acid alc. soln. of the II; furthermore, long continued action of  $\text{BaCO}_3$  may lead to discolorations and decompns. The method has accordingly been somewhat modified; the  $\text{NH}_4$  salt of II is treated in  $\text{H}_2\text{O}$  suspension with  $\text{H}_2\text{SO}_4$  and extd. with  $\text{Et}_2\text{O}$  and the ext. washed twice with  $\text{H}_2\text{O}$ , which removes the  $(\text{NH}_4)_2\text{SO}_4$ . The  $\text{Et}_2\text{O}$  is evapd., the II heated 12 hrs. on the  $\text{H}_2\text{O}$  bath with dil.  $\text{H}_2\text{SO}_4$ , cooled, filtered from the menthol, concd. *in vacuo*, extd. 12 hrs. with  $\text{Et}_2\text{O}$  to remove unchanged II and colored impurities, treated with  $\text{Ba}(\text{OH})_2$ , filtered from the  $\text{BaSO}_4$ , completely neutralized with  $\text{BaCO}_3$  with gentle heating, filtered, decolorized with charcoal, concd. *in vacuo*, treated at room temp. with  $N \text{ H}_2\text{SO}_4$  and alc. and concd. *in vacuo* at  $30^\circ$ , then over  $\text{CaCl}_2$  and finally over  $\text{H}_2\text{SO}_4$ ; yield of pure I, 59.5%. From this pure I were prepd. a no. of salts: Na, from I and 0.1 *N* NaOH in 80% alc., colloidal ppt. changing to needles with 1  $\text{H}_2\text{O}$  after drying *in vacuo* over  $\text{H}_2\text{SO}_4$ ,  $[\alpha]_D^{20}$  in  $\text{H}_2\text{O}$  (*c* 5.243)  $-0.56^\circ$  (initial),  $22.51^\circ$  (final, after about 1.5 hrs.); 1 g. anhyd. salt completely reduces 173 cc. of normal Fehling's soln. after 2 mins. boiling. *K*, cryst. powder with 1.5  $\text{H}_2\text{O}$ ,  $[\alpha]_D^{21}$  ( $\text{H}_2\text{O}$ , *c* 2.647)  $4.53^\circ$  (initial),  $20.02^\circ$  (final, after about 1.5 hrs.); anhyd. salt,  $[\alpha]_D^{25.15}$  ( $\text{H}_2\text{O}$ , *c* 1.240)  $-2.78^\circ$  (initial),  $22.47^\circ$  (final, after 2 hrs.).  $\text{NH}_4$ ,  $[\alpha]_D^{20}$  ( $\text{H}_2\text{O}$ , *c* 3.453)  $-4.05^\circ$  (initial)  $23.17^\circ$  (final, after 1.5 hrs.). *Ba*, amorphous,  $[\alpha]_D^{20.6}$   $17.45^\circ$  ( $\text{H}_2\text{O}$ , *c* 3.725), does not show mutarotation. *Brucine*, crystals with 1  $\text{H}_2\text{O}$  which they do not lose *in vacuo*

over  $P_2O_5$  at  $100^\circ$ , m.  $156-7^\circ$ ,  $[\alpha]_D^{20} -15.08^\circ$  ( $H_2O$ ,  $c$  3.117). Whereas the salts immediately after soln. are distinctly *l*-rotatory, the free I itself uniformly gave  $[\alpha]_D 11^\circ$ . Hudson, on the basis of his rule, calcd. that the initial rotation of the  $\alpha$ -form of I should be  $82^\circ$ , that of the  $\beta$ -form  $-5^\circ$ , and at his suggestion E. and R. tried, by varying the solvents and the method of prepn., the concn. and the temp. of the solns., to obtain lower rotations, but without success, even when the soln. was prepd. with ice  $H_2O$ . With a I liberated from its Na salt with the calcd. amt. of  $H_2SO_4$  at  $0^\circ$ , however, an initial  $[\alpha]_D$  of  $3.5^\circ$  was obtained. Possibly in their method of prepn. of the free I at some stage of the process the  $\beta$ -form partly changes into the  $\alpha$ -form, or perhaps the H. rule does not hold for the free acid, the H ions greatly influencing the equil. between the 2 forms; unlike the reducing sugars, both I and *d*-galacturonic acid reach their final rotation at room temp. very quickly (about 2 hrs.). The final rotation of I at  $0-20^\circ$  for  $c$  0.5-3.3 was around  $36^\circ$ .

C. A. R.

**Active molecule of oxalic acid.** F. OBERHAUSER AND J. SCHORMÜLLER. *Ann.* **470**, 111-28(1929); cf. *C. A.* **22**, 2142; Chichibabin, *C. A.* **23**, 1114.—Previous work being continued, it is found that by means of the activated  $(CO_2H)_2$  0.01 mg. Mn per l. may be detected. The action of  $H_2O_2$  on  $Fe^{++}$  in the presence of  $(CO_2H)_2$  gives in the cold a good yield of the activated form;  $Fe^{+++}$  does not react in this manner but rather retards the reaction.  $Fe^{++}$  (0.056 mg. as  $FeSO_4$ ) causes the sepn. of 0.1150 g. Hg as  $HgCl$  from  $HgCl_2$ ; there appears to be a min.  $(CO_2H)_2$  concn. for a given max.  $HgCl$  pptn.; there seems to be no definite relation between the  $HgCl_2$  or  $H_2O_2$  concns. and the pptn. of  $HgCl$ . The order of addn. is important, since no pptn. occurs if the  $FeSO_4$  is added to  $(CO_2H)_2$ ,  $HgCl_2$  and  $H_2O_2$ .  $K_2S_2O_8$  also acts as an activating agent, 1-g. atom causing the sepn. of 100 times that amt. of  $HgCl$ . Nitrates do not activate  $(CO_2H)_2$ , while nitrites do.  $(CO_2H)_2$  may also be activated electrolytically. Heating  $(CO_2H)_2$  with  $(CO_2NH_4)_2$  does not cause activation but the Hg quartz lamp causes pptn. of  $HgCl$ . Activated  $(CO_2H)_2$  loses its activity by heating to the b. p. The constitution of the activated mol. is discussed.

C. J. WEST

**Experiments in the glutaric series.** C. RAVENNA AND R. NUCCORINI. *Gazz. chim. ital.* **58**, 853-64(1928).—The expts. had as their object the synthesis of polypeptides from glutamine (I), following a procedure similar to that used by R. and Bosinelli (cf. *Gazz. chim. ital.* **49**, ii, 303(1919); **51**, ii, 281(1921); *C. A.* **15**, 68) for the synthesis of  $\beta$ -diptptides from asparagine (II). Moreover, since the anhydride of the dipeptide of aspartic acid was also obtained in a quite different way from  $NH_4$  malate (cf. *Beilstein*, 3rd Ed. **1**, 1389), it was attempted to prep. by analogy from  $H_4NO_2CCHOHCH_2CH_2CO_2NH_4$  (III) the dipeptide of  $HO_2CCHNH_2CH_2CH_2CO_2H$  (IV). The results show that the reactions are not analogous, no dipeptide being obtained from I under the conditions used with II, but rather  $HO_2CCHCH_2CH_2CO.NH$  (V) from the loss of  $NH_3$  from 1 mol.

of I. But though only 1 mol. of I is involved, the reaction is similar to that with II in that  $NH_3$  is eliminated at the expense of an amido and an amino group. Whereas, however, the amido group of II is essential to the imine condensation (the reaction not occurring with aspartic acid) a pyrrolidonecarboxylic acid is also obtained from (IV) (cf. Foreman, *C. A.* **9**, 632; Skola, *C. A.* **15**, 524). Like III it does not behave in an analogous manner to  $NH_4$  malate,  $NH_3$  instead of  $H_2O$  being eliminated from III. The I used in the expts. was prepd. from beets by extg. 5 kg. units of the latter with water, defecating with basic Pb acetate, filtering, adding excess aq.  $Hg(NO_3)_2$  (contg.  $HNO_3$ ), suspending the ppt. in water, decompg. with  $H_2S$ , filtering, distg. off the  $H_2S$  in *vacuo*, neutralizing the residue with  $NH_4OH$ , concg. in *vacuo*, adding EtOH, adding a little water and recrystg. by soln. in water and addn. of EtOH, which yields about 20 g. of I. No m. p. of I was found in the literature. The product obtained was variable, the m. p. being  $178-86^\circ$ . To prep.  $HO_2CCHOHCH_2CH_2CO_2H$  (VI), gluten was converted to the HCl deriv. of IV by the method of Fischer (*Ber.* **39**, 582(1906)), from which IV was obtained by the method of Hugounenq and Florence (*C. A.* **15**, 370), and from which in turn VI was prepd. by the method of Fischer and Moreschi (*C. A.* **7**, 86), purifying by the Zn salt, 50 g. of IV yielding 20 g. of VI. III was prepd. by passing  $NH_3$  into VI in anhyd. EtO. It could not be isolated without decompn. and was therefore used in soln. I (8 g.) refluxed in water (160 cc.) for 230 hrs., cooled,  $1/2$  N  $Ba(OH)_2$  (400 cc.) added, let stand in *vacuo* for 72 hrs., the  $Ba(OH)_2$  removed by titration with  $1/2$  N  $H_2SO_4$ , filtered and the filtrate concd. in *vacuo* to a very small vol., pptd. a cryst. mixt. which on sepn. with EtOH, yielded IV and V. The cryst. mixt. was composed of homogeneous crystals and may have been a labile compd. of IV and V. Similar preps. from IV and from mono- $NH_4$  glutamate yielded homogeneous mixts., probably also labile compds. of IV and V, as suspected by Menozzi and Appiani (*Gazz. chim. ital.* **24**, i, 374(1894))

and by Skola (C. A. 15, 524). Such compds. would be analogous to the addn. products of various amino acids and of amino acids and diketopiperazine (cf. Abderhalden and Sickel, C. A. 18, 2685; Pfeiffer and Angern, C. A. 19, 2033; 21, 897). To det. the behavior of III when heated, VI (3.70 g.) in anhyd.  $\text{Et}_2\text{O}$  was satd. with  $\text{NH}_3$ , the product was heated for 2 hrs. at  $150^\circ$ , extd. with hot  $\text{EtOH}$ , the ext. boiled with bone-black, filtered, concd., cooled and the cryst. ppt. purified from  $\text{EtOH}$ , which yielded 0.5 g. of  $\alpha$ -hydroxyglutaric acid diamide,  $\text{C}_6\text{H}_{10}\text{N}_2\text{O}_3$  (VII), m.  $181-2^\circ$  (decompn.); its aq. soln. gives with  $\text{KOH}$  and  $\text{CuSO}_4$  a violet color. Higher yields were obtained by heating III under pressure. Thus VI (12 g.) in anhyd.  $\text{Et}_2\text{O}$ , satd. with  $\text{NH}_3$ , the  $\text{Et}_2\text{O}$  eliminated, heated in a sealed tube for 2 hrs. at  $145-55^\circ$ , yields 4 g. of VII. VII (2.5 g.), heated 2 hrs. at  $185-90^\circ$ , cooled,  $\text{EtOH}$  added, extd. with anhyd.  $\text{Et}_2\text{O}$ , the  $\text{Et}_2\text{O}$  distd. until turbid, more  $\text{Et}_2\text{O}$  added until clear, petr. ether added until again turbid, let stand at  $0^\circ$ , filtered and the residue (0.50 g.) purified by soln. in  $\text{Et}_2\text{O}$  and pptn. with petr. ether, yields the compd.  $\text{C}_6\text{H}_7\text{O}_3\text{N}$ , which is probably the lactone of  $\alpha$ -hydroxyglutaric acid monoamide,  $\text{H}_2\text{NCOCH}(\text{CH}_2\text{CH}_2\text{CO}_2\text{O})$ , m.  $87-9^\circ$ , gives in water a violet color with

$\text{KOH}$  and  $\text{CuSO}_4$ . It may, however, have the dimeric constitution  $\text{H}_2\text{NCOCH}(\text{CH}_2\text{CH}_2\text{O.CO.CH}(\text{CH}_2\text{CH}_2\text{CONH}_2)\text{O.CO})$ . A mol. wt. detn. showed that the former

formula is the correct one.

C. C. DAVIS

**Constitution of Guareschi's cyanobutadiene acids. An attempt to synthesize  $\beta$ -isopropylglutaconic acid.** CHARLES S. GIBSON AND JOHN L. SIMONSEN. *J. Chem. Soc.* 1929, 1074-80.—Condensation of  $\text{AcH}$  and  $\text{NCCH}_2\text{CO}_2\text{Et}$  according to Guareschi (*Atti accad. sci. Torino* 36, 454(1900)) gives the *NH*, salt of 2,6-dihydroxy-3,5-dicyano-1-methylpyridine, thin prisms; hydrolysis with 60%  $\text{H}_2\text{SO}_4$  gives 2,6-dihydroxy-4-methylpyridine (Rogerson and Thorpe, *J. Chem. Soc.* 87, 1685(1905)).  $\text{Me}_2\text{CHCHO}$  and  $\text{NCCH}_2\text{CO}_2\text{Et}$  (cf. G., *Atti accad. sci. Torino* 38, 290(1902)) give the *NH*, salt of 2,6-dihydroxy-3,5-dicyano-4-isopropylpyridine, prisms, does not m.  $295^\circ$ ; hydrolysis gives a mixt. of 2,6-dihydroxy-3-cyano-4-isopropylpyridine, crystals with 1 mol.  $\text{H}_2\text{O}$ , m. about  $248^\circ$ , or anhyd., m.  $273^\circ$ , and 2,6-dihydroxy-3-isopropylpyridine, m.  $213-4^\circ$ ;  $\text{HCl}$  salt, plates; *p*-nitrobenzoyl deriv., m.  $200-1^\circ$ ; oxime, pale yellow, m.  $123-4^\circ$ . *Et*  $\alpha$ -bromo  $\beta$ -isopropylglutarate, from the acid chloride and  $\text{Br}$ , followed by esterification,  $b_p$   $178^\circ$ .  $\text{PhNEt}_2$  gives, as the main product, the *Et* ester of *dl*- $\alpha$ -hydroxy- $\beta$ -isopropylglutaric lactone,  $b_p$   $178^\circ$ ,  $n_D^{20}$  1.4466; the lactone acid is a viscous oil.

C. J. WEST

**Butane- $\alpha,\beta,\delta$ -tricarboxylic acid.** H. KILIANI. *Ber.* 62B, 640 1(1929).—In the  $\text{HI}$  reduction of the synthetic product from *K* *l*-mannosaccharate and  $\text{KCN}$ , K. had expected to obtain  $\text{HO}_2\text{CCH}_2\text{CH}(\text{CO}_2\text{H})\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$  (I) but was never able to do so. The I is very imperfectly described in the literature and K. accordingly obtained a supply of  $\text{NCCH}_2\text{CH}(\text{CN})\text{CH}_2\text{CH}_2\text{CO}_2\text{Et}$  from Leuchs, 24.75 g. of which he heated 2.5 hrs. on the  $\text{H}_2\text{O}$  bath, with occasional stirring, with 72 g.  $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$  and 372 cc.  $\text{H}_2\text{O}$ ; he then evapd. the mixt. nearly to dryness, stirred the residue with  $\text{H}_2\text{O}$ , decompd. it quantitatively with  $\text{H}_2\text{SO}_4$  and evapd. the filtrate to a thin sirup which on standing in the air deposited the I in columns or prisms which he purified by Leuchs and Möbis' method, with, however, 4 parts  $\text{C}_6\text{H}_6$  instead of 3 to 3 of  $\text{Me}_2\text{CO}$ . The I m.  $123^\circ$  and is optically inactive. None of the metal salts shows a definite tendency to crystallize; the  $\text{Ba}$  and  $\text{Ca}$  salts are more difficultly sol. in hot than in cold  $\text{H}_2\text{O}$ . The neutral K salt with  $\text{Cd}(\text{NO}_3)_2$  gives an amorphous ppt. which redissolves as long as any unchanged K salt remains. According to Steimetz the cryst. druses of I (from  $\text{H}_2\text{O}$ ) which, macroscopically, are beautiful, contain but few individual crystals with unetched faces and sharp angles; these are triclinic and apparently triclinic pinacoidal, a drawing of the predominant form is given.

C. A. R

**The constitution of isoborneol.** E. PUXEDDU. *Gazz. chim. ital.* 59, 59-69(1929). A survey of the literature on the problem of the isomerism of borneol (I) and isoborneol (II) leads to the conclusion that a study of their constitutions by means of  $\text{Cl}$  derivs. leads to insurmountable difficulties, and that there is much more hope in studying the oxidation of II to camphor (III) and reduction of III to II. With ordinary methods of oxidation, both I and II are transformed into camphor, but it was found that with a method of oxidation not hitherto applied to this problem, it is possible to oxidize I but not II to III. This method is a photochem. oxidation already described (cf. C. A. 14, 3368; 16, 2640). A mixt. of I (10 g.) in anhyd.  $\text{Et}_2\text{O}$  (400 cc.) and a filtered soln. of sublimed  $\text{FeCl}_3$  (10 g.) in anhyd.  $\text{Et}_2\text{O}$  (100 cc.) exposed to direct sunlight for 3 days, filtered, the black-brown residue washed with  $\text{Et}_2\text{O}$  and laid aside for future analysis, the filtrate exposed as before for 3 days, the new dirty white ppt. filtered and washed with  $\text{Et}_2\text{O}$  and laid aside, the new filtrate exposed as before for 2 days

until completely decolorized, filtered,  $\text{FeCl}_3$  (5 g.) in  $\text{Et}_2\text{O}$  (100 cc.) added to the filtrate, again repeatedly exposed to sunlight and filtered until colorless, and the whole process repeated until a total of 30 g. of  $\text{FeCl}_3$  is used, the  $\text{Et}_2\text{O}$  liquor finally concd. to a relatively small vol., the soln. extd. with water until a test for Fe is no longer obtained, and the non-aq. residue steam-distd., yields **III** and a brown-yellow resin which was not analyzed. The max. yield of **III** was 8 g. Using the same proportions of **II** and  $\text{FeCl}_3$  and following the same procedure, no **III** was obtained, but an unidentified colorless oil which was impure. Changing the proportions of **II** and  $\text{FeCl}_3$  and the time of exposure to light did not lead to the formation of **III**. Therefore the chief argument used in the past in support of the secondary alc. structure of **II**, viz., that it is always easily oxidized to **III**, is no longer significant. Furthermore there are instances known of the oxidation of tertiary alcs. to ketonic compds., and above all, methylcamphenylol, whose close relationship to **II** is evident, and which is certainly a tertiary alc., is also easily oxidized to **III** (cf. *Ann.* 340, 58; *Ber.* 38, 2461 (1905)). Possibility of tautomerism among the terpene alcs. exists. The discussion leads to the conclusion that **I** has a secondary camphoric structure and **II** a tertiary camphene structure. C. C. DAVIS

**Sugar anhydrides.** **I. Galactosen**  $< \alpha 1,5 > < \beta 1,6 >$ . FRITZ MICHEL. *Ber.* 62B, 687-93 (1929); cf. *C. A.* 22, 226.—Of the hitherto known sugar anhydrides, levoglucosan and  $\alpha$ -glucosan have been obtained in cryst. form and shown to be glucosan  $< \alpha 1,5 > < \beta 1,6 >$  and glucosan  $< 1,2 > < 1,5 >$ , resp. The others (for the most part non-cryst.) are generally assumed to be analogs of glucosan with a labile 1,2-ring. In this paper is described a cryst. galactose anhydride (**I**) which is very probably a

It was synthesized by a method by

which levoglucosan can also be obtained;  $\alpha$ -acetobromogalactose combines with  $\text{NMe}_3$  to form *tetraacetylgalactosidotrimethylammonium bromide* (**II**), which, from its rotation, probably belongs to the  $\beta$ -series, and the **II** with hot alkalis is hydrolyzed to **I**. Starting with a galactose deriv. contg. an  $< \alpha 1,5 >$ -ring, the  $\beta$ -ring in the anhydride may, theoretically, take in the 1,3-, 1,4- or 1,6-C atoms. If it is assumed that the 1,5-ring is without strain (which is the case if the angle between the O valences is assigned the probable value of  $110^\circ$ ), the above 3 rings would have strains of about  $110^\circ$ ,  $70^\circ$  and  $40^\circ$ , resp., i. e., the last should be the most stable. In spite of wide variation in the conditions of anhydridization, no isomer of **I** was ever obtained. **I** is stable towards Br and  $\text{KMnO}_4$ , reduces Fehling soln. only in traces even on long boiling, is not hydrolyzed by cold dil. acids but is completely on long boiling, and gives a mixt. of  $\alpha$ - and  $\beta$ -Me galactosides with HCl in MeOH. Small amts of **I** are also obtained by distg.  $\beta$ -galactose in a high vacuum and seeding the distillate. This great stability of **I** speaks decisively against a 1,3-ring structure. Furthermore, **I** is converted by  $\text{Me}_2\text{CO}$  with  $\text{CuSO}_4$  almost quant. into a well crystd. *acetone compd.* (**III**). These conditions are so mild that a ring shifting is improbable, and of the 3 possible anhydrides only **I** contains 2 adjacent HO groups in the *cis*-position to each other. With 1% HCl (which does not alter **I** itself), **III** regenerates **I**.  $\beta$ -Me galactoside (**IV**) similarly yields an *acetone compd.* (**V**), regenerating **IV** with 1% HCl. **III** has only 1 free HO group and condenses by the usual method with acetobromoglucose to an *acetonedisaccharide tetraacetate* which, however, was obtained only in amorphous form. **II** (13 g. from 20 g. acetobromogalactose, 7.5 g. abs. alc., 7.5 g.  $\text{C}_6\text{H}_6$  and 7.5 g.  $\text{NMe}_3$ ), m.  $173^\circ$  (decompn.),  $[\alpha]_D^{20}$   $31.1^\circ$  ( $\text{CHCl}_3$ ). **I** (5.9 g. from 33 g. **II** with  $\text{Ba}(\text{OH})_2$ ), m.  $220-1^\circ$ ,  $[\alpha]_D^{21}$   $-21.9^\circ$  ( $\text{H}_2\text{O}$ ), mol. wt.  $174^\circ$  ( $\text{H}_2\text{O}$ ); the mother liquors ( $\text{AcOEt}$ ) with  $\text{C}_6\text{H}_5\text{N}-\text{Ac}_2\text{O}$  yield 2.6 g. of the *triacetate*, m.  $73-4^\circ$ ,  $[\alpha]_D^{22}$   $-5.7^\circ$  ( $\text{CHCl}_3$ ). *Galactosido*  $< 1,5 >$ , *trimethylammonium bromide* (5.4 g. from 10 g. **II** and dil. HBr on the  $\text{H}_2\text{O}$  bath), m.  $162-4^\circ$ ,  $[\alpha]_D^{20}$   $37.6^\circ$  ( $\text{H}_2\text{O}$ ). *3,4-Isopropylidenegalactosan*  $< \alpha 1,5 > < \beta 1,6 >$  (**III**), m.  $151-2^\circ$ ,  $[\alpha]_D^{22}$   $-61.7^\circ$  ( $\text{H}_2\text{O}$ ),  $-73.3^\circ$  ( $\text{CHCl}_3$ ). *3,4-Isopropylidene- $\beta$ -methylgalactoside*  $< 1,5 >$  (**V**), m.  $134-5^\circ$ ,  $[\alpha]_D^{17}$   $20.96^\circ$  ( $\text{H}_2\text{O}$ ). C. A. R.

**Compounds of hydroxides of the alkaline earths with sugars.** JOHN E. MACKENZIE and JAMES P. QUINN. Univ. of Edinburgh. *J. Chem. Soc.* 1929, 951-64.—A review is given of the literature of the subject. CaO (0.9 mol.) added to 1 mol. sucrose in 5% aq. soln. and pptd. with 500 cc. 60% EtOH (200 cc. sugar-alkali soln.) gives 60% of  $C_{12}H_{22}O_{11} \cdot CaO \cdot 2H_2O$  (termed monolime-monosucrose), from which the  $H_2O$  is removed by triturating with 60% EtOH; evapn. of the aq. soln. over  $P_2O_5$  gives  $C_{12}H_{22}O_{11} \cdot CaO \cdot 5$  (or 6)  $H_2O$ , from which the  $H_2O$  may also be removed by 60% EtOH; this compd. is unstable at room temp. Addn. of 500 cc. of 60% EtOH to 250 cc. CaO-satd. sucrose soln. ppts. dilime-monosucrose, amorphous, sepg. with 6  $H_2O$ , soly. 1 in 37.7 parts  $H_2O$ . Heating the CaO-satd. sucrose soln. to 80° gives trilime-monosucrose, sepg. with 6  $H_2O$ ; soly. 15.33 g. anhyd. compd. per 1.  $H_2O$ .  $Me_2SO_4$  and the 3CaO salt give mixts. of methylated sucroses. Higher lime-sucrose compds., such as  $C_{12}H_{22}O_{11} \cdot 4CaO \cdot H_2O$  and  $C_{12}H_{22}O_{11} \cdot 9CaO \cdot H_2O$ , were obtained by heating solns. which were not satd. with CaO. One mol. each of sucrose and KCl in the min. quantity of boiling  $H_2O$  deposit the cryst. compd.  $C_{12}H_{22}O_{11} \cdot KCl \cdot 2H_2O$ . A sucrose soln. (200 cc. of 20%) in which 1 mol. SrO has been dissolved at 75°, on cooling deposits the compd.  $C_{12}H_{22}O_{11} \cdot SrO \cdot 6H_2O$ ; soly. per 1., 43.95 g. of anhyd. salt at 16° with  $[\alpha]_D^{15}$  42.00°. When slightly more than 3 mols. SrO are added to a boiling 15% sucrose soln. and the boiling continued 2 mins., the compd.  $C_{12}H_{22}O_{11} \cdot 2SrO$  ppts.; soly. 11.89 g. per 1. at 100°; the soln. at 15° had  $[\alpha]_D^{15}$  37.79°. Higher SrO compds. could not be obtained pure. The only compd. with BaO is  $C_{12}H_{22}O_{11} \cdot BaO$ ; soly. 22.10 g. per 1. at 20°,  $[\alpha]_D^{20}$  43.89°. Glucose and CaO at 0° give the complex  $C_6H_{12}O_6 \cdot CaO \cdot 2H_2O$ , amorphous, which is stable for months if dry, but if wetted, it decomps. overnight. Attempts to isolate other hydrates gave inconclusive results. Negative results were obtained in attempts to prep. compds. of CaO, SrO and BaO with  $\alpha$ - and  $\beta$ -Me glucosides. Fructose forms the compd.  $C_6H_{12}O_6 \cdot CaO \cdot 6H_2O$ , which loses 4 mols.  $H_2O$  *in vacuo* at 9° over concd.  $H_2SO_4$ ; soly. at 15°, 0.847 as the monohydrate,  $[\alpha]_D^{15}$  —39.05°. Higher lime-fructoses could not be obtained pure. No evidence was found of compd. formation with  $\alpha$ - or  $\beta$ -Me fructosides. *Monolime-monomaltose* crystallizes with 1  $H_2O$ ,  $C_{12}H_{22}O_{11} \cdot CaO \cdot H_2O$ ; soly. 18.9 g. per 1.,  $[\alpha]_D^{15}$  120.4°. Me maltoside does not give compds. with the alk. earth oxides. Monolime-monolactose is stable when dry; soly. 18.6 g. per 1.,  $[\alpha]_D^{15}$  46.06° (approx.), since decompn. sets in immediately on soln.  $\beta$ -Me lactoside does not yield compds. with the oxides.

**Unsaturated reduction products of sugars and their derivatives.** XI. 2-Desoxycellobiose (celldesose) and derivatives of 2,3-bisdesoxycellobiose. MAX BERGMANN and WILHELM BREUERS. Kaiser Wilhelm-Inst. für Lederforschung. *Ann.* 470, 38-51 (1929); cf. *C. A.* 19, 2478.—Cellobial (12 g.) in 60 cc. 2 N  $H_2SO_4$  at 0°, upon shaking, dissolves in 6-7 hrs.; after another hr. the acid is removed with Ba, the filtrate warmed to 60°, filtered through charcoal and concd. *in vacuo*; heating with 95% EtOH causes crystn.; the resulting *celldesose* (2-desoxycellobiose) (I), m. 184° and decomps. 200° (cor.),  $[\alpha]_D^{21}$  23.2° ( $H_2O$ ); in  $C_6H_5N$  (0.1595 g. in 8.1964 g.  $C_6H_5N$ ),  $[\alpha]_D$  after 5 mins. is 9.82°, changing (during 48 hrs.) to 37.8°. One g. I corresponds to 51 cc. Fehling soln.; I also reduces  $NH_4OH$ - $AgNO_3$  and alk. I soln. Alkali decomps. it with production of a yellow color; mineral acids decomp. it with darkening of the soln. A pine splinter in the presence of HCl is colored green; with Fe contg.  $H_2SO_4$  and AcOH there results a blue color. The yield of I is 56%. I (4 g.) in 200 cc. anhyd. MeOH contg. 1% HCl, allowed to stand 1 hr., gives 38-48% of the *methylactolide*, which is sepd. into 2 isomers by fractional crystn.; *methylcelldesoside A*, m. 169-71° (cor.),  $[\alpha]_D^{22}$  40° (70% aq. soln.); the *B isomer*, m. 220° (decompn.),  $[\alpha]_D^{20}$  —19.9° (3.5% aq. soln.); these do not reduce Fehling soln. and are decompd. by mineral acids; 0.01 N HCl at 100° gives 97% of CHO group; from the soln. 85% of I may be recovered. With 0.001 N HCl, 50% sapon. occurs after 1 hr. at 100°; with 0.1 N HCl, the sapon. is complete in less than 5 mins. Pentaacetyl- $\psi$ -cellobial (10 g.) in 10 parts anhyd. MeOH contg. 0.25% HCl gives, after 15 min. at room temp., *pentaacetyl- $\psi$ -cellobial  $\alpha$ -methylactolide*, m. 131.5-2.5°,  $[\alpha]_D^{21}$  65.3° (in  $C_2Cl_4$ ); Br is added in  $CHCl_3$ ; hot Fehling soln. is not reduced.  $Ba(OH)_2$  in dil.  $Me_2CO$  sapons. this deriv., giving the  $\psi$ -cellobial  $\alpha$ -methylactolide, m. 112-3° (cor.),  $[\alpha]_D^{21}$  97.3° (in  $H_2O$ ), 97.3° (AcOH); the dry compd. absorbs 1.5 mols.  $H_2O$ ; in  $H_2O$  Br is rapidly taken up; the compd. is very sensitive to acids. Catalytic reduction gives the *2,3-bisdesoxycellobiose  $\alpha$ -methylactolide*, m. 147-8° (cor.),  $[\alpha]_D^{21}$  90.2° ( $H_2O$ ); it is hygroscopic and takes up 1 mol.  $H_2O$  from the air. XII. New reduction products of sugars. *Ibid* 54-61.—Catalytic

reduction of triacetyl- $\psi$ -glucal in AcOH with Pd gives 80% of diacetylhexane-1,4,5,6-tetrol  $< 1.5 >$  anhydride (I),  $b_{0.1} 102-3^\circ$  (bath temp.  $125-30^\circ$ ),  $n_D^{19} 1.4511$ ; a by-product is apparently triacetyl-dihydro- $\psi$ -glucal,  $b_{1.2-1.5} 150-7^\circ$  (bath temp.  $180-90^\circ$ ),  $n_D^{17} 1.4545$ . Catalytic reduction (Pt and AcOH) of diacetyl- $\psi$ -glucal gives I and probably a mixt. of diacetyl-dihydro- $\psi$ -glucal,  $b_{0.2-0.4} 140-50^\circ$ . Sapon. with  $Ba(OH)_2$  gives hexane-1,4,5,6-tetrol  $< 1.5 >$  anhydride,  $b_{1.5} 122^\circ$ , does not react with CO reagents, does not reduce Fehling soln.  $H_2SO_4$  deriv., m.  $99^\circ$ ,  $[\alpha]_D^{26} 8.62^\circ$  ( $C_2Cl_4$ ); BzH and  $ZnCl_2$  at  $100^\circ$  gives the BzH deriv., m.  $137-7.5^\circ$ ;  $PCl_5$  gives a dichlorohexanediol anhydride,  $b_{0.8} 55^\circ$ . Reduction of hexacetyl- $\psi$ -cellobial gives pentaacetylglucosidohexanetetrol anhydride, m.  $133-4^\circ$  (cor.),  $[\alpha]_D^{21} 18.1^\circ$  ( $C_2Cl_4$ ); this also results upon reducing the penta-Ac deriv.; a 2nd product of this latter reduction is pentaacetyl-bisdesoxycellobiose, m.  $153-5^\circ$ ,  $[\alpha]_D^{19} 32.1^\circ$  ( $C_2Cl_4$ ). Reduction of the penta-Ac deriv. with Pd according to Willstätter-Waldschmidt-Leitz gives 75% of pentaacetylglucosidohexanetetrol anhydride, m.  $109-10^\circ$ ,  $[\alpha]_D^{20} 20^\circ$  ( $C_2Cl_4$ ); this may be further reduced to the hexane deriv. Diacetyl-arabinal (17 g.) heated with 400 cc.  $H_2O$  20 min., the  $H_2O$  removed *in vacuo* and the product treated with  $Ac_2O$  and  $C_6H_5N$  in the cold, gives 62% of diacetyl- $\psi$ -arabinal,  $b_{0.8} 120-4^\circ$ ,  $n_D^{24} 1.4625$ .

C. J. WEST

**Constitution of pine wood lignin. VIII. The nutritive sap of the pine.** PETER KLASON. *Ber.* 62B, 635-9(1929); cf. *C. A.* 22, 2147.—The sap was prepd. by Tiemann's method, being scraped with glass plates from the freshly felled trunks. It is faintly acid, contains about 10% dry matter, has a pleasant odor of freshly baked rye bread, contains little coagulable protein but considerable peptones and amino acids. The N content of the dry matter varies from 0.3 to 0.8%. The sap therefore rapidly spoils on standing. The scrapings are dild. with an equal vol. of boiling  $H_2O$ , let stand overnight, squeezed through cloth, filtered and concd. to a sirup. When the coniferin content is considerable the sirup gradually sets to a half-solid, stable mass. The solid matter consists mostly of sugar. In one case the sap contained, according to the power of reducing Fehling soln., 36% sugar, and, after inversion, 60% of the dry wt. Apparently there are present not inconsiderable amts. of sucrose for alc. fermentation of the non-inverted sap gives more alc. than corresponds to the reducing value. The pentose is chiefly xylose; there is little or no arabinose. To det. whether any lignin was present the sap was evapd. to dryness on the  $H_2O$  bath, shaken with 66%  $H_2SO_4$  until everything had apparently dissolved (12 hrs.), dild. with  $H_2O$ , filtered through an alundum crucible, heated 12 hrs. in the crucible under  $N$  HCl in a covered weighing bottle in a steam bath, completely freed of the  $H_2SO_4$  and dried at about  $70^\circ$ . As the lignin is very hygroscopic the crucible was cooled and weighed in a stoppered weighing glass. In 1 case the lignin, called *protolignin*, was 14% of the dry wt. As the sap contains coniferin and the coniferyl alc. in it is highly sensitive to even very dil. mineral acids, part of the lignin isolated must have been produced from the coniferin; it is probably a product intermediate between coniferyl alc. and the pentoses. The coniferin was hydrolyzed with emulsin according to Tiemann. Neither it nor the coniferyl alc. give the lignin reactions but the free alc. is quite auto-oxidizable and its solns. after a short time distinctly show the lignin reactions. If the hydrolyzed soln. is allowed to stand at room temp. for several days with asbestos contg. Pt sponge the oxidation proceeds so far that it can be followed analytically by micro methods.  $\beta$ - $C_{10}H_7NH_2$  HCl gave a yellow ppt. with 2.60%, *i. e.*, a mixt. of dimeric and trimeric forms. The oxidized soln., satd. with  $SO_2$ , heated 12 hrs. in a steam bath, concd. and freed from  $H_2SO_4$ , gave with  $C_{10}H_7NH_2$  HCl a ppt. with exactly the same properties as that obtained from the sulfite waste liquors. Coniferin itself in the solid state is not auto-oxidizable but if the sap scrapings are dried at room temp. and extd. with hot  $H_2O$ , the ext. gives strong lignin reactions. The ppt. thrown down from the sap by  $C_{10}H_7NH_2$  HCl is not homogeneous but consists largely of free  $C_{10}H_7NH_2$ ; the filtrate gradually deposits a yellow, extremely finely granular substance of the compn.  $2C_{10}H_9O_3 + C_{10}H_9N + 2H_2O$ , apparently an anil of a protolignin. The sap, satd. with  $SO_2$  and heated 12 hrs. in a steam bath, gives with  $C_{10}H_7NH_2$  HCl a yellow ppt. similar in all respects to that obtained from the sulfite waste liquors. These results show that coniferyl alc., as obtained from coniferin with emulsin, can change even at room temp. into a trimeric coniferyl aldehyde identical with the lignin of wood. In the nutritive sap of the pine there is a protolignin which combines with  $SO_2$  and condenses with  $C_{10}H_7NH_2$  and by loss of  $H_2O$  changes into polymers of coniferyl aldehyde. It can also lose  $H_2O$  directly to form coniferyl alc. *Addendum.*—Pauly and Feuerstein (*C. A.* 23, 2982) claim that the  $C_{10}H_7NH_2$  salt of coniferylhydrosulfonic acid

synthesized by K. from vanillin is really the hydrosulfonate of a condensed AcH, as they were able to obtain it from AcH alone. But a condensation product of AcH alone can contain no MeO. K.'s prepn. contained 6.3% MeO (calcd., 7.7%) and further purification with cold MeOH-Et<sub>2</sub>O gave a product with 7.1% MeO. There are 2 coniferyl aldehydes: one (K.'s) is labile and combines with SO<sub>2</sub>; the other (Pauly's) is stable and does not react with SO<sub>2</sub>. Only the labile form is found in living organisms and the error into which, according to P., K. fell in prepg. his aldehyde was necessary in order to obtain the labile form.

C. A. R  
**Constitution of cellulose xanthates. II.** TH. LIESER. *Ann.* **470**, 104-10 (1929); *C. A.* **22**, 4792.—Cellulose xanthate and CH<sub>2</sub>N<sub>2</sub> in MeOH give a *monomethyldicellulose* (I), colorless, with the appearance of cotton cellulose; CH<sub>2</sub>N<sub>2</sub> does not react with cellulose. Hydrolysis with 75% H<sub>2</sub>SO<sub>4</sub> at room temp. for 20 hrs., followed by fermentation of the glucose, gives *2-methylglucose*, yellow, amorphous, whose hydrazone m. 176°. This was synthesized from  $\beta$ -pentaacetylglucose through 1-chloro 2 tri-chloroacetyl-3,4,6-triacetoglucofucose, 1-chloro-3,4,6-triacetoglucofucose and *3,4,6-triaceto-2-methyl methylglucoside*, m. 121°, which, on sapon, on sapon, and treatment with PhNHNH<sub>2</sub>, gives the same hydrazone, m. 176°. Since the I does not show the viscose reaction, it may be concluded that the sec. HO group in the 2-position of cellulose enters into the viscose reaction.

**Keto-lactol tautomerism. II.** Influence of the cyclohexane ring on the tautomeric character of cyclohexane-1-acetone-1-malonic acid, a comparison with cyclopentane-1-acetone-1-malonic acid, and synthesis of the corresponding  $\delta$ -keto-monobasic acids. MUHAMMAD QUDRAT-I-KHUDA. *J. Chem. Soc.* **1929**, 713-21; cf. *C. A.* **23**, 2152.—*Cyclohexane-1-acetone-1-malonic acid*, C<sub>8</sub>H<sub>10</sub>>C(CH<sub>2</sub>COMe)CH(CO<sub>2</sub>H). (I), and the corresponding *cyclopentane acid* (II), in the liquid state exists as an equal mixt. of the keto and lactol forms,  $\text{RR}'\text{C} \cdot \text{CH}_2 \cdot \text{C}(\text{OH})\text{Me} \cdot \text{O} \cdot \text{CO} \cdot \text{CHCO}_2\text{H}$ . The

lactols could not be isolated, but the amt. of each form present in the equil. mixts. was deduced from the amt. of ketomonobasic acid,  $\text{RR}'\text{C}(\text{CH}_2\text{COMe})\text{CH}_2\text{CO}_2\text{H}$ ,  
 $\text{O} \text{---} \text{CMe}$

formed by decompn. of the keto form, and of dilactone (III)

from the lactol form. As expected from a consideration of the alteration of the C tetrahedral angle by the inclusion of the C as a spiran atom in cyclohexane and cyclopentane rings, I shows more marked tautomeric behavior than II (I gives 68-70% dilactone; II, 47-52%). 27.6 g. cyclohexenylacetone, b<sub>16</sub> 90°, d<sub>4</sub><sup>20</sup> 0.9404, n<sub>D</sub><sup>16</sup> 1.47751 (prepd. by Wallach's method, *C. A.* **7**, 1002), heated 6 hrs. in abs. alc. with 16.8 g. NCCH<sub>2</sub>CONH<sub>2</sub> and 4.6 g. Na, yields 35 g. *cyclohexanespiro-cyclo-1,3-glyoxy 6-cyano-3-methyl-5-piperidone*, C<sub>8</sub>H<sub>10</sub>>C·CH<sub>2</sub>·C(OH)Me·NH·CO·CHCN, m. 258° (charring).

sol. in caustic alkali and dil. acid. 25 g. of the spiro compd., heated 28 hrs with 25 g. KOH in 100 cc. water, gives 25 g. I, m. 116°, decomps. about 118°; *semicarbazone*, m. 183° (decompn.); normal *Et ester* (from the dry Ag salt and EtI), b<sub>14</sub> 192°, d<sub>4</sub><sup>20</sup> 1.0681, n<sub>D</sub><sup>18.5</sup> 1.46984, [R<sub>L</sub>]<sub>D</sub> 77.3 (calcd. 77.2) (*semicarbazone*, m. 104°). I (5 g.), heated at 130-40° 5-6 hrs., forms 68% *dilactone* (III, RR' = C<sub>6</sub>H<sub>10</sub>>), m. 141°, and *cyclohexane-1-acetone-1-acetic acid* (IV), C<sub>8</sub>H<sub>10</sub>>C(CH<sub>2</sub>COMe)CH<sub>2</sub>CO<sub>2</sub>H (1.3 g.), m. 73°. The dilactone is the only product when I is heated in C<sub>6</sub>H<sub>6</sub>, or treated with concd. HCl or a dehydrating agent. Hydrolysis of the dilactone with hot dil. caustic alkali gives I. Cyclohexane-1,1-diacetic anhydride (91 g.) (prepd. by heating with Ac<sub>2</sub>O the diacid (V), Thorpe, *C. A.* **14**, 1522; **5**, 2848)) heated 4 hrs. with MeOH (40 cc.) forms the acid ester; *Ag salt*; *Me ester* (VI) of IV (from the acid ester with SOCl<sub>2</sub> and then ZnMeI), b<sub>18</sub> 152°, d<sub>4</sub><sup>20.4</sup> 1.0363, n<sub>D</sub><sup>20.4</sup> 1.46748, [R<sub>L</sub>]<sub>D</sub> 56.81 (calcd. 57.08) (*semicarbazone*, m. 137°). IV, m. 73° (with a little V), is prepd. from VI and KOH in MeOH; *semicarbazone*, m. 185°. VI with the calcd. amt. of EtONa gives quant. cyclohexane *spiro-cyclohexane-3,5-dione*, m. 169-70°, also obtained (with some VI) from IV and alc. HCl, instead of the expected ethoxy-lactone, which would have been evidence of the lactol form of IV. IV reacts in the lactol form with excess AcCl, yielding the unsatd. *lactone*, C<sub>8</sub>H<sub>10</sub>>C·CH·CMe·O·CO·CH<sub>2</sub>, b<sub>17</sub> 144°, d<sub>4</sub><sup>19.9</sup> 1.0533, n<sub>D</sub><sup>19.9</sup> 1.4952, [R<sub>L</sub>]<sub>D</sub>

49 85 (calcd. 49.79), hydrolyzed by alc. KOH to IV. *Cyclopentane-spiro-cyclo-3-hydroxy-6-cyano-3-methyl-5-piperidone* (VII) (18 g.), m. 282°, is prepd. from cyclopentenylacetone (26 cc.),  $\text{NCCCH}_2\text{CONH}_2$  (16.8 g.), and Na (4.6 g.), and is hydrolyzed to II, half-pyramid crystals, m. 106°, decomp. near 130°; semicarbazone, m. 177°; normal *Et ester* (from II and alc. HCl),  $b_{13}$  179°,  $d_4^{18}$  1.0767,  $n_D^{18}$  1.4632,  $[\text{R}_L]_D$  72.68 (calcd. 72.78) (semicarbazone, m. 109°). II (5 g.) at 140–50° 5 hrs. forms about 47% dilactone (III,  $\text{RR}' = \text{C}_4\text{H}_8 >$ ), m. 139°, and 2.05 g. *cyclopentane-1-acetone-1-acetic acid* (VIII), m. 53°. The dilactone also arises from II and concd. HCl or any dehydrating agent, or from VII and concd. HCl. Cyclopentane-1,1-diacetic anhydride, boiled 3 hrs with MeOH, yields the oily acid Me ester; *Ag salt*; *Me ester* (IX) of VIII (44 g. from 60 g. acid ester,  $\text{SOCl}_2$  and  $\text{ZnMeI}$ ),  $b_{12}$  130°,  $d_4^{17.7}$  1.0386,  $n_D^{17.7}$  1.46021,  $[\text{R}_L]_D$  52.24 (calcd. 52.46) (semicarbazone, m. 119°). IX, heated with Na and alc., gives quant. cyclopentane-spiro-cyclohexane-3,5-dione, m. 136°, best prepd. in this way. IX is hydrolyzed by KOH in aq. alc. to VIII, m. 53° (semicarbazone, m. 191°) and a little cyclopentane-1,1-diacetic acid. VIII with MeOH and HCl yields IX. VIII, heated 1 hr. with  $\text{AcCl}$ , forms the unsatd. lactone,  $b_{14}$  124°,  $d_4^{18}$  1.0573,  $n_D^{18}$  1.49043,  $[\text{R}_L]_D$  45.42 (calcd. 45.17), hydrolyzed by alc. KOH to VIII.

JANET D. SCOTT

**The catalytic hydrogenation of phenol and naphthol ethers with hydrogen and platinum.** E. WASER, H. SOMMER, C. LANDWEER AND C. GAZA. *Helv. Chim. Acta* 12, 118–43 (1929).—A review of the literature is given covering the hydrogenation of various aliphatic-aromatic and pure aromatic ethers and their substituted compds. Not only does hydrogenation take place but splitting reactions and complete removal of the alkoxy groups also occur. In this work the hydrogenation of the alkyl Ph ethers of the type  $\text{PhOR}$ , where R is an alkyl group contg. 1 to 6 C atoms, was studied, as was that of 1- and 2- $\text{C}_{10}\text{H}_7\text{OEt}$  and guaiaacol. The reaction was allowed to take place in the presence of Pt black at ordinary temp. and at a max pressure of 1 m of water above atm. These conditions are much milder than those used heretofore. In all cases the products were similar and consisted of the compds,  $\text{C}_6\text{H}_{11}\text{OR}$ ,  $\text{C}_6\text{H}_{11}\text{OH}$ , cyclohexane, ROH and RH. These products are possible if 3 different reactions occur, which may be represented by the equations: (a)  $\text{PhOR} + 3\text{H}_2 \longrightarrow \text{C}_6\text{H}_{11}\text{OR}$ , (b)  $\text{PhOR} + 4\text{H}_2 \longrightarrow \text{C}_6\text{H}_{11}\text{OH} + \text{RH}$ , (c)  $\text{PhOR} + 4\text{H}_2 \longrightarrow \text{C}_6\text{H}_{12} + \text{ROH}$ . Thus for simple hydrogenation 3 mols. of  $\text{H}_2$  are required whereas 4 mols are utilized in the other reactions. An av. of 3.66 mols. was actually absorbed before reaction ceased. This signifies that the product of simple hydrogenation forms about  $\frac{1}{3}$  of the total. As a mechanism for reactions (b) and (c) it was suggested that a split between the C and O atoms first takes place, resulting in the formation of benzene or phenol according to whether the bond is broken between the O atom and the alkyl or the Ph group. Benzene is then hydrogenated while phenol first undergoes keto-enol tautomerism with the formation of the compd.,  $\text{CH}:\text{CH}:\text{CH}:\text{CH}:\text{CH}_2:\text{CO}$ , from which  $\text{C}_6\text{H}_{11}\text{OH}$  is

obtained by hydrogenation. That the ketone is formed as an intermediary product is shown by the fact that when  $\text{NH}_2\text{CONHNH}_2 \cdot \text{HCl}$  was present during the hydrogenation, the semicarbazone of cyclohexanone was always obtained regardless of the size of the alkyl group. A mechanism for the hydrogenation of the benzene ring, involving the catalyst, is also given. It was observed in every case that while the  $\text{H}_2$  is being absorbed, the catalyst is suspended through the liquid medium, but when the reaction is approaching completion it ppts. When fresh ether is added the catalyst is again found suspended until the absorption of  $\text{H}$  ceases. Furthermore, some particles of the catalyst procure a metallic luster. This behavior may be explained by the following series of reactions:

The catalyst was prepd. in the manner described in C. A. 23, 388. As already mentioned cyclohexane, cyclohexanol and in the presence of  $\text{H}_2\text{NCONHNH}_2 \cdot \text{HCl}$ , the semicarbazone of cyclohexanone was isolated in every case. The other products consisted of the paraffin, alc. and hexahydro ether peculiar to each ether hydrogenated. The hexahydro derivs. of anisole and phenetole are known; the following lists the *hexahydrophenyl ethers* used with their b. p.,  $d_4^{20}$ ,  $n_D^{20}$ , and M.R., found and calcd. *Pr*,  $b_{128}$  170.5–1.5°, 0.8665, 1.43936, 43.18, 43.20. *iso-Pr*,  $b_{716}$  168–9°, 0.9235, 1.48332,

43.74, 43.20. *Bu*,  $b_{711}$  193.5–4.5°, 0.8664, 1.43853, 47.36, 47.82. *iso-Bu*,  $b_{711}$  175–7°, 0.8618, 1.44137, 47.89, 47.82. *iso-Am*,  $b_{711}$  206–7°, 0.8523, 1.44136, 52.76, 52.44. *Hexyl*,  $b_{728}$  222.5–4.5°, 0.8515, 1.44375, 57.32, 57.06.  $\alpha$ -C<sub>10</sub>H<sub>17</sub>OEt absorbs 5.59 mols. of H<sub>2</sub> whereas simple hydrogenation requires 5 mols. The products of hydrogenation were analogous to those obtained in the Ph series. They were decalin,  $\alpha$ -decahydronaphthol, EtOH and  $\alpha$ -decahydronaphthyl Et ether,  $b_{718}$  236–8°.  $\beta$ -C<sub>10</sub>H<sub>17</sub>OEt absorbs 5.66 mols. of H<sub>2</sub>. The products were *cis*- $\beta$ -decahydronaphthol, EtOH, *cis*-decalin and  $\beta$ -decahydronaphthyl Et ether,  $b_{718}$  238–40°, 0.9419, 1.47718, 54.67, 54.86. Guaiacol absorbs 4.06–4.38 mols. of H<sub>2</sub>. The products consisted of a very complex mixt. but the following were isolated: cyclohexane, cyclohexanol, MeOH, hexahydroguaiacol,  $b_{730}$  175–80°,  $d_{20}^{20}$  0.9775,  $n_D^{20}$  1.45687, M.R. found 36.24, calcd. 35.48, and possibly hexahydroanisole. I. M. LEVINE

**Properties of conjugated compounds. VII. Additive formation of cyclohexenes.** ERNEST H. FARMER AND FRANK I. WARREN. *J. Chem. Soc.* 1929, 897–909; cf. *C. A.* 23, 2156.—4,5-Dimethyl-*cis*- $\Delta^4$ -tetrahydrophthalic anhydride (I), m. 78°, results quant by keeping CH<sub>2</sub>:CMeCMe:CH<sub>2</sub> and maleic anhydride 24 hrs. at room temp.; heating a few mins. with 10 times its wt. of H<sub>2</sub>O gives the acid, m. 180–92° reverting partly to the anhydride at its m. p. Decompn. of the ozonide gives an acid, m. 186°, probably 3-acetyl-4-methylcyclopentan-4-ol-1,2-dicarboxylic acid (II). An acid, which appears to be a lactonized form of II, is formed from I and HNO<sub>3</sub> (1.1), m. 219°. Addn. of maleic anhydride to BrCH<sub>2</sub>CH:CHCH:CHCH<sub>2</sub>Br in C<sub>6</sub>H<sub>6</sub> by heating at 100° for 5.5 hrs., gives 67% of 3,6-dibromomethyl-*cis*- $\Delta^4$ -tetrahydrophthalic anhydride, m. 98°, this could not be oxidized with KMnO<sub>4</sub> with the production of cryst. products; the anhydride is not hydrolyzed by boiling H<sub>2</sub>O; boiling with aq. Na<sub>2</sub>CO<sub>3</sub> gives 63% of the dilactone (III) of 3,6-dihydroxymethyl-*cis*- $\Delta^4$ -tetrahydrophthalic acid, m. 159–63°; attempts to oxidize the Na salt proved futile; KMnO<sub>4</sub> caused degradation to (CO<sub>2</sub>H)<sub>2</sub>. Catalytic reduction of III gives the lactone of 3,6-dihydroxymethylhexahydrophthalic acid, m. 119–20°. Maleic anhydride and Et *trans-trans*-muconate, heated 18 hrs. at 100°, give 50% of 3,6-dicarboxy- $\Delta^3$ -tetrahydrophthalic anhydride, m. 185–8°; *tetra-Et ester*, m. 75°. Catalytic reduction of the acid gives 3,6-dicarboxyhexahydrophthalic acid (hexahydroprehnitic acid), crystg. with 1 H<sub>2</sub>O, m. 168° (IV); *tetra-Et ester*,  $b_{13}$  238°; dianhydride, m. 223–5°. Sorbic acid and maleic anhydride at 100° for 36 hrs. give 80% of 6-carboxy-3-methyl-*cis*- $\Delta^3$ -tetrahydrophthalic anhydride, m. 174°; boiling with H<sub>2</sub>O for 1 hr. gives the acid, m. 194°; no definite products could be isolated from the oxidation with O<sub>3</sub> or KMnO<sub>4</sub>; catalytic hydrogenation gives 6-carboxy-3-methyl-*cis*-hexahydrophthalic acid, crystg. with 1 H<sub>2</sub>O, m. 194–6°. The addn. of maleic anhydride to cyclohexadiene gives dicyclooctenedicarboxylic acid, oxidized by alk. KMnO<sub>4</sub> to a tetrabasic acid, m. 168°, identical with IV. The cyclopentadiene addn. compd., on oxidation, gives a tetrabasic acid, m. 181–2° (anhydride formation); *tetra-Et ester*,  $b_{14}$  226°; it was impossible to det. whether this is cyclopentane-1,2,3,4-tetracarboxylic acid or cyclobutane-1,2,3-tricarboxy-4-acetic acid. The *trans*-hexatriene maleic anhydride addn. compd. is 3-ethylidene-*cis*- $\Delta^4$ -tetrahydrophthalic anhydride,  $b_8$  148°, m. 51.5°; boiling with H<sub>2</sub>O for 10 mins. gives the acid, m. 164–6°; PhNH<sub>2</sub> gives the *anilic acid*, m. 174°. The same compd. was derived from *cis*-hexatriene. C. J. WEST

1,3-Diphenyl-3-cyclohexen-5-one. A. D. PERKOV. *Ber.* 62B, 642–5 (1929).—See *C. A.* 23, 2156. C. A. R.

The electron theory as applied to organic compounds, particularly benzene. MAX ULMANN. *Z. Elektrochem.* 35, 268–74 (1929); cf. *C. A.* 23, 377; Loewen, *C. A.* 23, 1626.—U. amplifies his theory, using PhOH as an illustration. FOSTER D. SNELL

1,4-Dimethyl-3,5,6-trichloro-2-aminobenzene and some of its derivatives. J. BUREŠ AND T. RUBŠ. *Časopis Českoslov. Lékárnictva* 8, 225–31, 258–64 (1928).—By the action of Cl<sub>2</sub> on 2,5-Me<sub>2</sub>C<sub>6</sub>H<sub>3</sub>NHAc in glacial AcOH at ordinary temp. and pressure, without catalyst, B. and R. obtained 1,4-dimethyl-3,5,6-trichloro-2-acetamidobenzene, m. 222°, which on hydrolysis gave the 2-amino compd., m. 206° (I). From I were prepd. the Bz deriv., m. 223°, the picrate, m. above 100° (decompn.), and the 2-methyl-amino compd., m. 62°. There were also prepd. 1,4-dimethyl-3,5,6-trichloro-2-hydroxybenzene, m. 175° (Me ether, m. 91°; Et ether, m. 79°; benzoate, m. 101°; acetate, m. 103°); 1,4-dimethyl-3,5,6-trichlorobenzene, m. 96°; 1,4-dimethyl-2,3,5,6-tetrachlorobenzene, m. 223°; 1,4-dimethyl-3,5,6-trichloro-2-benzonitrile, m. 213°.

WILLIAM J. HUSA

The bromination of *p*-anisidine and 1-methoxy-4-acetamidobenzene and the nitration of 3,5-dibromo-1-methoxy-4-acetamidobenzene and some of their derivatives. E. BUREŠ AND M. NEDĚLKOVÁ. *Časopis Českoslov. Lékárnictva* 9, 23–8, 41–51, 78–83

(1929).—3,5-Dibromo-1-methoxy-4-aminobenzene, m. 83°, was prepd. by the action of  $\text{Br}_2$  on *p*-anisidine in alc., without catalyst, at ordinary temp. and pressure. The action of  $\text{Br}_2$  on 4-AcNHC<sub>6</sub>H<sub>4</sub>OMe in glacial AcOH yielded 3,5-dibromo-1-methoxy-4-acetamidobenzene, m. 205°. The following derivs. were prepd.: 4-diacetyl-amino, m. 136°; 4-benzoylamino, m. 198°; 4-methylamino, b. 186°; 4-ethylamino, b. 234°; HCl salt, picrate (m. 97°) and sulfate of 3,5-dibromo-1-methoxy-4-aminobenzene; 3,5-dibromo-1-methoxy-4-benzonitrile, m. 177°; 3,5-dibromo-1-methoxybenzene, m. 38°; 3,5-dibromo-1-methoxy-4-chlorobenzene, m. 76°; 3,4,5-tribromo-1-methoxybenzene, m. 79°; 3,5-dibromo-1-methoxy-4-iodobenzene, m. 98°; 3,5-dibromo-1-methoxy-2-nitro-4-aminobenzene, m. 172°; 3,5-dibromo-1-methoxy-2-nitro-4-acetamidobenzene, m. 206.5°; 3,5-dibromo-1-methoxy-2-nitrobenzene, m. 85°; 3,5-dibromo-1-methoxy-2-nitro-4-chlorobenzene (sublimes without melting); 3,5-dibromo-1-methoxy-2-nitro-4-iodobenzene, m. 207°.

WILLIAM J. HUSA

**3,4-Dibromo-*o*-anisidine and some of its derivatives.** E. BUREŠ AND M. SOUČEK. *Časopis Českoslov. Lékařnictva* 8, 295-9, 317-25 (1928).—By the action of  $\text{Br}_2$  on 2-AcNHC<sub>6</sub>H<sub>4</sub>OMe in glacial AcOH was obtained 3,4-dibromo-1-methoxy-2-acetamidobenzene, m. 146°, which on hydrolysis yielded the 2-amino deriv. (I), m. 103°. The following derivs. were prepd.: sulfate and HCl salt of I; 3,4-dibromo-1-methoxy-2-methylaminobenzene, b. 162°; 2-benzoylamino compd., m. 137-8°; 2-HO compd., m. 94° (II) (benzoate, m. 114°; acetate, m. 90°); 3,4-dibromo-1-methoxybenzene, b. 127°; 3,4-dibromo-2-chloro-1-methoxybenzene, m. 98°; 2,3,4-tribromo-1-methoxybenzene, m. 101°; 3,4-dibromo-2-iodo-1-methoxybenzene, m. 94°.

W. J. H.

**Transformation of phenylnitroamines into nitroanilines.** I. ALAN E. BRADFELD AND KENNEDY J. P. ORTON. *J. Chem. Soc.* 1929, 915-21, cf. C. A. 2, 1700, 2232.—3-Bromo-*p*-tolylnitroamine (I), from the anine and  $\text{HNO}_3$  in  $\text{AcOH} \cdot \text{Ac}_2\text{O}$ , m. 65°; 2,4-dibromophenylnitroamine, m. 77°; both are highly sensitive to light. In the transformation a by-product is formed which is capable of coupling with a phenol to give an azo compd. Under the conditions employed, with at least 10 mol proportions of the catalyzing acid, nitroamine and by-product formation proceed as side reactions of the 1st order. No stoichiometrical relation exists between the relative amt. of nitroaniline and by-product; the ratio varies with the concn. of the catalyzing acid, the diln. of the  $\text{AcOH}$  medium and the nitroamine employed, but, in general, has the same value for different acids at equiv. concns. With  $\text{H}_2\text{SO}_4$  as catalyst, in 98%  $\text{AcOH}$ , transformation of I proceeds at about 0.5 the rate of transformation with HCl of the same normality; diln. of the medium to 50%  $\text{AcOH}$  causes a marked decrease in the velocity of the reaction. The behavior of  $\text{HNO}_3$  is abnormal. The anion of the acid catalyst is not fundamentally concerned in the reaction, which is in harmony with the view that in the transformation of the nitroamines into nitroanilines an intramol. process plays the important part.

C. J. WEST

**Action of diazonium salts on the lateral chains of unsaturated compounds. II.** A. QUILICO AND E. FLEISCHNER. *Gazz. chim. ital.* 59, 39-49 (1928); cf. Q. and Freri, C. A. 23, 597.—In the present work, the reaction between unsatd. phenolic ethers and diazonium salts is extended to isoeugenol (I). Because of a free OH group and an *o*-position available for coupling, I reacts in the lateral chain, the latter being partially eliminated. The reaction can be carried out either in  $\text{AcOH}$  or in  $\text{EtOH}$ , but a tendency with  $\text{AcOH}$  to resinify makes  $\text{EtOH}$  preferable for a high yield and pure product.  $p\text{-O}_2\text{NC}_6\text{H}_4\text{NH}_2$  (3.5 g.) in glacial  $\text{AcOH}$  (20 cc.) and concd.  $\text{H}_2\text{SO}_4$  (2.5 cc.) diazotized with  $\text{AmNO}_2$  (5 cc.), the product purified by pptg. 3 times with  $\text{Et}_2\text{O}$  and resoln. in glacial  $\text{AcOH}$ , dissolved in a min. of  $\text{AcOH}$ , 95%  $\text{EtOH}$  (60-70 cc.) added, made ice-cold, freshly distd. I (4 g.) in  $\text{EtOH}$  (20 cc.) added slowly with vigorous agitation, let stand 10-12 hrs., filtered, the residue washed with a little  $\text{EtOH}$ , and recrystd. from  $\text{EtOH}$ , yields about 6 g. of a compd. whose properties conformed to 3,4-MeO(HO)-C<sub>6</sub>H<sub>3</sub>CH:NNHC<sub>6</sub>H<sub>4</sub>NO<sub>2</sub>-*p* (II), m. 225° (cf. 227° of Biltz and Sieden, *Ann.* 324, 232 (1902)). This shows that I behaves like anethole, and it also shows the great difference in character of the reaction of I and diazo compds. when the medium is acid or alc. instead of alkali (cf. *Ber.* 37, 4135 (1904); *Gazz. chim. ital.* 35, i, 55 (1905); 36, ii, 1 (1906)). Prepn. of the di-Ac deriv. (III) of II further confirmed its identity. Vanillin and IV (equal wts.) in glacial  $\text{AcOH}$  heated 0.25 hr. on a water bath and the ppt. recrystd. from  $\text{EtOH}$  also yield II. Acetylvanillin (cf. *Ber.* 7, 614 (1874)) (1.94 g.), glacial  $\text{AcOH}$  (25 cc.) and  $p\text{-O}_2\text{NC}_6\text{H}_4\text{NHNH}_2$  (IV) (1.53 g.) heated on a water bath and the ppt. recrystd. from boiling  $\text{EtOH}$ , yields acetylvanillin *p*-nitrophenylhydrazone, golden yellow, m. 179°, gives a characteristic violet color when sapond. by boiling aq. alkalis, and when boiled with  $\text{Ac}_2\text{O}$  and  $\text{AcONa}$  it forms III.  $p\text{-O}_2\text{NC}_6\text{H}_4\text{NH}_2$  (3.5 g.) diazotized with  $\text{NaNO}_2$  (1.8 g.) and concd. HCl (7.5 cc.), filtered, the filtrate poured

very slowly into ice-cold I (4 g.) in 5% KOH (60 cc.), let stand, filtered, washed with water, the residue dissolved in dil. KOH, and reprecipitated with AcOH, yields 100% of the hydroxyazoisoeugenol obtained by Puxeddu (cf. *Rend. accad. Lincei* [5], 15, 131 (1906)). 2,4-(O<sub>2</sub>N)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>NH<sub>2</sub> (V) (1 g.) in glacial AcOH (10 cc.) and concd. H<sub>2</sub>SO<sub>4</sub> (0.6 cc.) diazotized by the method of Hantzsch, the product purified with Et<sub>2</sub>O, suspended in EtOH (40 cc.), made ice-cold, alc. I added, let stand 24 hrs., filtered, washed with EtOH, and the residue recrystd. from boiling glacial AcOH, yields the compd. C<sub>14</sub>H<sub>11</sub>O<sub>6</sub>N<sub>4</sub> (VI), m. 250° (decompn.), gives a violet-red color in aq. alkalis. VI is also formed by heating vanillin (1.5 g.) and V (2 g.) in glacial AcOH for 0.25 hr. on a water bath, and purifying with boiling AcOH. Concd. Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub> added very slowly to V in boiling aq. 1% NaOH, until the purple color disappears and a copious yellow ppt. is formed, filtered, the residue washed with EtOH, yields the compd. C<sub>14</sub>H<sub>15</sub>O<sub>4</sub>N<sub>3</sub>, yellowish, m. 192° (decompn.), is unstable in air and is probably MeO(HO)C<sub>6</sub>H<sub>3</sub>CH<sub>2</sub>NHNHC<sub>6</sub>H<sub>3</sub>N<sub>3</sub>O<sub>2</sub> (VII). The attempt was made to reduce the Ac deriv. of VII in EtOH with Sn and HCl, but only *p*-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>.HCl)<sub>2</sub>, a white resin and a trace of guaiaacol were found. This behavior can be explained by the great instability of the vanillylamine (cf. Nelson, C. A. 13, 2198). The allyl isomers behave quite differently. No product could be isolated from safrole and diazotized *p*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>, either in AcOH or in EtOH. With safrole and diazotized (O<sub>2</sub>N)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>NH<sub>2</sub>, a small quantity of a red compd., m. 139-40°, insol. in aq. acids and alkalis, was isolated. Its low m. p. indicated that it was of a different type from the products obtained from propenyl ethers. Neither could a cryst. product be obtained from styrene (cf. Meyer, Irschick and Schlosser, C. A. 8, 2878). To explain mechanism of the reaction, other unsatd. compds. were studied, e. g., PhCH:CHCO<sub>2</sub>H (VIII), PhCH:CHCO<sub>2</sub>Et (IX) and PhCH:CHCH(OH) (X), but these compds. remained unaltered after several days' contact with the diazo compd. This is not surprising, since in many other cases negative substituents inhibit the additive property of olefinic double bonds (cf. Ber. 37, 3317 (1904); J. prakt. Chem. 72, ii, 201 (1905); Bauer and Moser, C. A. 1, 1407). The similar behavior of anethole I and other propenyl ethers in distinction to the behavior of the corresponding allyl isomers can be foreseen by reference to the work of Angeli (*Mem. accad. Lincei* [5], 14, 627 (1924); cf. C. A. 18, 1118, 2502) on the similarity of behavior of C<sub>6</sub>H<sub>5</sub> derivs. of the AC<sub>6</sub>H<sub>4</sub>B type, where A and B are in *o*- or *p*-positions, with the corresponding aliphatic A-B derivs. Researches by Meyer (C. A. 5, 2624; 6, 88; 7, 993, 2539; 8, 2878) on enolic-ketonic tautomerism show that the activity of olefinic double bonds is gradually increased by the presence of an OH or alkyloxy group united directly to 1 of the double bonded C atoms, i. e., compds. of the RC(OH)·CHR' and RC(OAk)·CHR' type have much higher additive power than compds. of the RCH:CHR' type. Phenolic ethers have a structure of the 1st type, whereas allyl ethers, e. g., eugenol and safrole, are comparable to the compds. HOCH<sub>2</sub>CH:CH<sub>2</sub> and MeOCH<sub>2</sub>CH:CH<sub>2</sub> and therefore react with much greater difficulty, as do VII, IX and X, as expts. confirm. The great activity of propenyl ethers which occurs in many reactions (cf. Q, C. A. 23, 1628) is to be attributed to the presence, in the *p*-position to the lateral chain, of a OH or alkyloxy group, which renders active the double bond of the lateral chain. These ethers should therefore be regarded as true enols. The expts. offer a new method of distinguishing between propenyl and allyl chains to be added to the classic methods of Angeli with HNO<sub>2</sub>, of Balbiano with AcOHg and of Bruni with NO<sub>2</sub> deriv. addn. compds.

C. C. DAVIS

**New syntheses among the amino acids. II.  $\alpha$ -Anisylideneamino- $\beta$ -lactones.** GAETANO MINUNNI and SALVATORE D'URSO (WITH V. BELLECCI and I. OTTAVIANO) *Gazz. chim. ital.* 59, 32-9 (1929); cf. C. A. 23, 1120.—The work on the reaction between aromatic  $\alpha$ -aldoximes and esters of  $\beta$ -ketonic acids was continued in 2 directions by studies of (1) the action of AcCH<sub>2</sub>CO<sub>2</sub>Et (I) and of BzCH<sub>2</sub>CO<sub>2</sub>Et (II) on other aromatic aldoximes, the results with  $\alpha$ -anisaldoxime (III) being described in the present paper, and (2) some interesting transformations of arylideneaminolactones, which will be described in a forthcoming paper. In the prepn. of III by the method of Bamberger and Scheutz (*Ber.* 34, 2024 (1901)), a higher yield can be obtained and the process be made more convenient by chilling with ice the alk. soln. during passage of the CO<sub>2</sub>. This gives crystals m. 62-4°. III reacts more energetically than benzaldoxime with I, and the reaction must be carried out at a lower temp. I, III and crystd. H<sub>3</sub>PO<sub>4</sub> (equal parts) heated on a water bath for 0.5 hr. after the mass has solidified, the product ground into a paste with water, mixed with 10% Na<sub>2</sub>CO<sub>3</sub>, filtered, washed with water, the residue mixed with EtOH, yield 14 g. of crude product, which, boiled with EtOH, cooled, filtered, washed with EtOH, suspended in EtOH (200 cc.) heated to boiling, C<sub>6</sub>H<sub>5</sub> added until soln. is complete, filtered hot and cooled, yields  $\alpha$ -anisylideneamino- $\beta$ -

crotonolactone,  $\text{MeOC}_6\text{H}_4\text{CH}:\text{NC}:\text{CMe}.\text{O}.\text{CO}$  (IV), m. 179–80°. Prolonged boiling with

alc.  $\text{PhHNHNH}_2$  converts IV to anisalphenylhydrazone, while heating IV with 1% KOH forms anisaldehyde (V). II (10 g.), III (5 g.) and  $\text{H}_3\text{PO}_4$  (5 g.) heated about 2 hrs. on a water bath, cooled, ground with a little EtOH, filtered, washed with EtOH, the combined filtrate and wash liquor allowed to evap., the mother liquor concd. and steam-distd., the residue ground with EtOH (and heated if necessary) leaves a residue which, combined with the previous residues, and the mixt. boiled in EtOH (100 cc. per 30 g.) for 1 hr., chilled with cold water, filtered, washed with EtOH, and the residue finally recrystd. from boiling EtOH, yields 70% of  $\alpha$ -anisylideneamino- $\beta$ -cinnamolactone (VI), yellow, m. 166–6.5°. V heated on a water bath with 1% KOH, cooled and extd. with  $\text{Et}_2\text{O}$ , yields V, while the  $\text{Et}_2\text{O}$ -insol. liquor treated with dil. HCl ppts. an unidentified hydrolytic yellow cryst. compd. which gives an acidic soln. in hot water.

C. C. DAVIS

**3,4-Methylenedioxyphenylarsonic acid.** ISIDORE E. BALABAN. *J. Chem. Soc.* 1929, 1088–93.—These derivs. were prepd. in the hope of obtaining 3,4-(HO) $_2$ C $_6$ H $_2$ -AsO $_3$ H $_2$  by a convenient manner. 3,4-CH $_2$ (O) $_2$ C $_6$ H $_2$ NH $_2$ , through the diazo reaction, gives 41.7% of 3,4-methylenedioxyphenylarsonic acid (I), crystg. with 0.75 mol. H $_2$ O, decomp. 270°; Ca and Ba salts, cryst.; Mg salt, amorphous. Attempts to open the CH $_2$ O $_2$  ring by SOCl $_2$ , H $_2$ SO $_4$  and a phenol or AlCl $_3$  in PhCl failed. Reduction of I gives 65% of arsenopyrocatechol methylene ether, pale yellow, amorphous powder. Nitration of I at 0° gives 59.5% of the 6-NO $_2$  deriv. (II), bright yellow, m. 231° (decompn.), (also obtained from 5,3,4-O $_2$ N(CH $_2$ O) $_2$ C $_6$ H $_2$ NH $_2$  in 36.9% yield); heating with NaOH gives a blood-red color; reduction of II gives the 6-NH $_2$  deriv. (III), needles, sol. in 80% HCO $_2$ H, diazotizes normally and on reduction gives 6,6'-diaminoarsenopyrocatechol methylene ether, bright yellow, amorphous. Ac deriv. of III, prisms. 4-Nitro-1,2-diacetoxylbenzene, m. 98°; 4-NH $_2$  deriv., m. 114° (41.8% yield); while this diazotizes normally, no arsonic acid could be isolated, 4-Nitropyrocatechol dibenzyl ether, m. 97° (48.7% yield); 4-NH $_2$  deriv., m. 92° (50% yield); Ac deriv., m. 150°; again no arsonic acid could be isolated through the diazo reaction. Toxicity data are given.

C. J. WEST

**Chemotherapy of some bromine derivatives of phenylarsonic acids and arsenobenzenes.** ALAN HAYTHORNTHWAITTE. *J. Chem. Soc.* 1929, 1101–4.—2,4-H $_2$ N(AcNH)-C $_6$ H $_2$ AsO $_3$ H $_2$  through the diazo reaction gives 2-bromo-4-acetamidophenylarsonic acid, plates (Ba and Ca salts, needles; Mg salt, amorphous); the 4-NH $_2$  deriv. forms plates whose Ca and Mg salts are amorphous. 3-Bromo-4-hydroxyphenylarsonic acid, plates (Ca salt, cryst.; Mg salt, amorphous). The following arsenobenzenes, all yellow, were prepd. in the usual manner: 4,4'-di-Br, 3,3'-dibromo-4,4'-diamino, 2,2'-dibromo-4,4'-diamino, 4,4'-diacetamido, and its 2,2'-di-Br deriv., all of which are insol. in NaOH; the following are sol.: 3,3'-dibromo-4,4'-dihydroxy, 5,5'-dibromo-3,3'-diamino-4,4'-dihydroxy, and its di-Ac deriv. The min. curative dose and toxicity data are given for these Br-contg. compds. and the corresponding compds. without the Br; in no case did the compd. produced show an improved chemotherapeutic index when compared with the corresponding compd. contg. no Br.

C. J. WEST

**Some derivatives of arylthioarsinous acids.** HARRY J. BARBER. *J. Chem. Soc.* 1929, 1020–4.—4-H $_2$ NC $_6$ H $_4$ AsO $_3$ H $_2$  and HSCH $_2$ CO $_2$ H in *N* NaOH give a neutral soln. from which acids ppt. di[carboxymethyl] 4-aminophenylthioarsinite, m. 142–3°; with HSCH $_2$ CO $_2$ Et there results in 2 *N* HCl the HCl salt, m. 100–5°, of the di[carbethoxymethyl] deriv., oily. With NH $_3$  the ester gives the di[carbamylmethyl] deriv., m. 145°, best obtained by using HSCH $_2$ CONH $_2$ . Di[carboxymethyl] 3-amino-4-hydroxyphenylthioarsinite, m. 157–8°; the amide, m. 132–3°; with cysteine-HCl there results the di[ $\beta$ -carboxy- $\beta$ -aminoethyl] deriv., needles. Di[carboxymethyl] 5-acetamido-2-hydroxyphenylthioarsinite, m. 172–4°; 4-carbamylmethylaminophenylthioarsinite, m. 90°; 8-acetamido-3-hydroxy-1,4-benzisoxazine (I), m. 212° (decompn.); the amide, m. 233–5°; di[ $\beta$ -carboxy- $\beta$ -aminoethyl] deriv. of I, needles; di[ $\beta$ -hydroxyethyl] deriv., needles. In these compds. acid does not liberate HSCH $_2$ CO $_2$ H nor does hydrolytic fission occur with alkali; the salts are neutral and generally extremely sol. in H $_2$ O and have pronounced therapeutic activity. In alk. soln. they show an intense nitroprusside reaction. They can be titrated with I in acid or NaHCO $_3$  soln. They are oxidized in alk. soln. by atm. O to the parent arsonic acid.

C. J. WEST

**Thiolacetamide as a reagent for identifying arsonic acids.** HARRY J. BARBER. *J. Chem. Soc.* 1929, 1024–6.—Arsonic acids react with HSCH $_2$ CONH $_2$  to form thioarsinites, ArAs(SCH $_2$ CONH $_2$ ) $_2$ , with definite m. ps., which may prove a means of identifying and characterizing these acids. With easily sol. arsonic acids they are

added to 4 mols.  $\text{HSCH}_2\text{CONH}_2$  in hot  $\text{H}_2\text{O}$ ; with sparingly sol. acids it is more convenient to use the Na salt of the acid; with  $\text{NO}_2$  compds. the reaction should be carried out in the cold. The following thioarsiniles were prepd.: *Ph*, m. 129–30°; 2-amino-phenyl, m. 140°; 4-aminophenyl, m. 145°; 2-hydroxyphenyl, m. 161–3°; 4-hydroxyphenyl, m. 160–2°; 3-amino-4-hydroxyphenyl, m. 132–3° (3-Ac deriv., m. 176°); 5-acetamido-2-hydroxyphenyl, m. 188°; 3-amino-4-methylaminophenyl, m. 141–3°; 4-chlorophenyl, m. 134–6°; 4-chloro-3-nitrophenyl, m. 142–3°; 3,5-diamino-4-hydroxyphenyl, m. 159–61°; 2,6-diacetamidophenoxyacetic-4-arsonic acid, m. 157°; 8-acetamido-3-hydroxy-1,4-benzisoxazine-6-arsonic acid, m. 233–5°.

C. J. WEST

**Interaction of tellurium tetrachloride and dimethylaniline.** GILBERT T. MORGAN AND HENRY BURGESS. *J. Chem. Soc.* 1929, 1103–6.— $\text{TeCl}_4$  (15.2 g.) in 160 cc.  $\text{Et}_2\text{O}$ , added to 21 cc.  $\text{PhNMe}_2$  in 200 cc.  $\text{Et}_2\text{O}$ , gives practically quant. *bisdimethylaniline-tellurium tetrachloride* (I), yellow, turns green at 137° and m. to a blue liquid 144–5° with elimination of  $\text{Te}$ ; it slowly decomps. in moist air. Boiling 28.5 g. of I with 200 cc.  $\text{H}_2\text{O}$  for 15 min. gives 8 g. of 4,4'-tetramethyldiaminodiphenyl telluridichloride (II), bright yellow, turns blue 181° and m. 188–9°; it dissolves in concd.  $\text{H}_2\text{SO}_4$  with effervescence, forms a  $\text{HCl}$  salt, m. 136–7°, and with  $\text{NaNO}_2$  in dil.  $\text{HCl}$  gives  $\text{TeO}_2$  and  $p\text{-ONC}_6\text{H}_4\text{NMe}_2$ ;  $\text{NaI}$  in  $\text{Me}_2\text{CO}$  gives the diiodide, dark red, m. 158–9° (decompn.). Reduction with  $\text{K}$  metabisulfite gives 4,4'-*tr*-methyldiaminodiphenyl telluride, pale olive green, m. 128–30°, which slowly oxidizes to a colorless insol. solid. The aq. mother liquors from II, on concn., give *trisdimethylaniline hydrochloride-tellurium tetrachloride*,  $(\text{PhNMe}_2\text{HCl})_3\text{TeCl}_4\cdot\text{EtOH}$ , greenish yellow, m. 119–21°, hygroscopic, decompd. by alkalis.  $\text{TeCl}_4$  and  $\text{Ph}_2\text{NMe}$  in  $\text{Et}_2\text{O}$  give 80% of an indigo-blue solid, which was not convertible by  $\text{H}_2\text{O}$  into a dichloride; concn. of the  $\text{Et}_2\text{O}$  gives a small amt. (about 5%) of 4,4'-diphenyldimethylaminodiphenyl telluridichloride, primrose-yellow, m. 170–2°; warming with concd.  $\text{H}_2\text{SO}_4$  gives an intense violet to blue color, while  $\text{HNO}_3$  gives a deep wine-red tint.

C. J. WEST

**Action of ammonia on halogen-substituted arsines.** V. IPAT'EV, G. RASUVAIEV AND V. STROMSKI. *Ber.* 62B, 598–604 (1929); *J. Russ. Phys.-Chem. Soc.* 61, 3–12 (1929).— $\text{Ph}_2\text{AsCl}$ ,  $\text{MeAsCl}_2$  and  $\text{PhAsCl}_2$  were chosen to study the action of  $\text{NH}_3$  on substitution derivs. of  $\text{AsCl}_3$ , a subject on which very little work had been done before. Dry  $\text{NH}_3$  was passed through sols. of these compds. in  $\text{C}_6\text{H}_6$  carefully protected from atm. moisture; the weakly exothermic reaction proceeded smoothly to the end and in every case the  $\text{Cl}$  was quant. split off as  $\text{NH}_4\text{Cl}$  with formation of the corresponding  $\text{R}_2\text{AsNH}_2$  or  $\text{RAs:NH}$ , the latter polymerizing to  $(\text{RAs:NH})_n$  where  $n$  is 4–6. The structure of the products is shown by their hydrolytic cleavage into  $\text{NH}_3$  and oxidation by  $\text{H}_2\text{O}_2$  to  $\text{R}_2\text{AsO}_2\text{H}$  or  $\text{RAsO}_2\text{H}_2$ . *Diphenylarsenamide*, crystals of faint aromatic odor, m. 53°, mol. wt. in freezing  $\text{C}_6\text{H}_6$  284–93, irritates the skin in powd. form or in the vapors of a volatile solvent. *Methylarsenimide*, crystals of faint but unpleasant odor, irritating to the mucous membranes, m. 205°, mol. wt. in freezing  $\text{C}_6\text{H}_6$  647–48.5. *Phenylarsenimide*, m. about 265°, mol. wt. in freezing  $\text{C}_6\text{H}_6$  642, is very irritating to the skin in powd. form, in the vapor of a volatile solvent and in soln. The  $\text{NH}_2$  or  $\text{NH}$  groups in these compds. are very loosely held; even atm. moisture splits them off as  $\text{NH}_3$ , the primary compd.  $\text{Ph}_2\text{AsNH}_2$  being the most sensitive; of the secondary amines, the aliphatic are more sensitive than the aromatic derivs. The ease with which they are hydrolyzed results in a rapid change in their m. ps., especially when they are in soln., and makes it necessary in their prepn. to use most carefully dried materials and solvents and to exclude atm. moisture in all the operations, otherwise the product will be mixed with the oxide or consist of the pure oxide. They are oxidized so energetically by concd.  $\text{HNO}_3$  that they are completely decompd., often with deflagration, likewise when heated with  $\text{Na}$ . With  $\text{HCl}$  in  $\text{Et}_2\text{O}$  they do not form an  $\text{HCl}$  addn. product but decomp. into  $\text{NH}_4\text{Cl}$  and, apparently, the original chloroarsine. C. A. R.

**Manufacture of synthetic phenol from halogen derivatives of benzene.** W. J. HALE AND EDGAR C. BRITTON. *Rev. gén. mat. color* 32, 100–2 (1928); cf. C. A. 21, 249; 22, 950.—A description for the process of manuf. of phenol from  $\text{Cl}$  derivs. of benzene using  $\text{Ph}_2\text{O}$  for heat transfer. References.

E. M. SHELTON

**"Oxidizing" action of alkalis (preliminary communication).** RUDOLF LEMBERG. *Ber.* 62B, 592 (1929).—Lock recently (C. A. 23, 827) reached the conclusion that in alkali fusions there often occur, not oxidations but dehydrogenations, with replacement of a  $\text{H}$  atom by the group  $\text{KO}$ , and announced his intention of extending his investigations to the direct hydroxylation of aromatic compds. Lemberg therefore feels impelled to report briefly some expts. he carried out some time ago but which he has been unable to take up again. Barth found that  $\text{PhOH}$  fused with  $\text{NaOH}$  yields di- and trihydroxyphenols, dihydroxydiphenyls and considerable amts. of dark phenol-

like products of high mol. wt., and, although he noted the evolution of H, he assumed the reaction was an oxidation by atm. O. If, however, PhONa and alkali contg. H<sub>2</sub>O are fused with stirring in a closed Ni app. in a current of N the same products are obtained; at a definite temp. there quite suddenly occurs a vigorous evolution of H. The Ni of the app. appreciably lowers the dehydrogenation reaction without diminishing the yield of dark, H<sub>2</sub>O-insol. but for the most part alkali-sol. products. The m-H dehydrogenation with NaOH competes with that between 2 phenol mols. C. A. R.

**Introduction of the triphenylmethyl group into phenols. II.** DOUGLAS V. N. HARDY. *J. Chem. Soc.* 1929, 1000–11; cf. C. A. 22, 1970. —According to their behavior toward an AcOH-H<sub>2</sub>SO<sub>4</sub> soln. of Ph<sub>3</sub>COH, phenols and phenolic ethers fall into 3 groups: I (those which undergo condensation), PhOH, PhOMe, PhOEt, *o*-MeC<sub>6</sub>H<sub>4</sub>OMe, *o*-MeC<sub>6</sub>H<sub>4</sub>OEt, *m*-MeC<sub>6</sub>H<sub>4</sub>OH, *o*-C<sub>6</sub>H<sub>4</sub>(OH)<sub>2</sub>, *o*-HOC<sub>6</sub>H<sub>4</sub>OMe, *o*-C<sub>6</sub>H<sub>3</sub>(OMe)<sub>2</sub>, *m*-C<sub>6</sub>H<sub>3</sub>(OMe)<sub>2</sub>, *p*-C<sub>6</sub>H<sub>4</sub>(OH)<sub>2</sub>, 1,2,3-C<sub>6</sub>H<sub>3</sub>(OH)<sub>3</sub>, 1,2,3-C<sub>6</sub>H<sub>3</sub>(OMe)<sub>3</sub>, thymol,  $\alpha$ - and  $\beta$ -C<sub>10</sub>H<sub>7</sub>OH, *o*-Cl- and *o*-BrC<sub>6</sub>H<sub>4</sub>OH; II (those under whose influence the Ph<sub>3</sub>COH is reduced to Ph<sub>2</sub>CH), *p*-MeC<sub>6</sub>H<sub>4</sub>OH, *p*-MeC<sub>6</sub>H<sub>4</sub>OMe, *p*-MeC<sub>6</sub>H<sub>4</sub>OEt, *o*- and *p*-ClC<sub>6</sub>H<sub>4</sub>OH, *o*-BrC<sub>6</sub>H<sub>4</sub>OH, *p*-C<sub>6</sub>H<sub>4</sub>(OMe)<sub>2</sub>; III (those which are unreactive), *o*- and *p*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>OH, picric acid, *o*- and *p*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>OMe, *o*-HOC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H, *o*-MeOC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H, Cl<sub>3</sub>C<sub>6</sub>H<sub>2</sub>OH, Br<sub>3</sub>C<sub>6</sub>H<sub>2</sub>OH and Cl<sub>3</sub>C<sub>6</sub>H<sub>2</sub>OMe. The reactions were carried out by dissolving 6 g. Ph<sub>3</sub>COH and 6 g. of phenol in 60 cc. AcOH by warming and then adding 10 g. H<sub>2</sub>SO<sub>4</sub>. PhOEt gives 6.38 g. 4-ethoxytetraphenylmethane, m. 191°. *m*-C<sub>6</sub>H<sub>4</sub>(OMe)<sub>2</sub> gives a mixt. of Ph<sub>2</sub>CC<sub>6</sub>H<sub>3</sub>(OH)<sub>2</sub> and 1,3-dimethoxy-1,6-bis(triphenylmethyl)benzene, m. 271°. 1,2,3-C<sub>6</sub>H<sub>3</sub>(OH)<sub>3</sub> gives 3,4,5-trihydroxytetraphenylmethane, crystalline, with 2 mols. Me<sub>2</sub>CO, m. 255° (decompn.); the *tri*-Me ether, m. 178°.  $\alpha$ -C<sub>10</sub>H<sub>7</sub>OH gives 7.25 g. of 4-triphenylmethyl-1-naphthol, m. 204–45°, and about 0.8 g. of 2,4-bis-triphenylmethyl-1-naphthol, m. 235–6°.  $\beta$ -C<sub>10</sub>H<sub>7</sub>OH gives 6.4 g. of 1-triphenylmethyl-2-naphthol, m. 228°. Thymol gives 4-hydroxy-2-methyl-5-isopropyltetraphenylmethane, which exists in 2 cryst. forms, m. 106–7° and 157°. *o*-ClC<sub>6</sub>H<sub>4</sub>OH gives 2.1 g. 3-chloro-4-hydroxytetraphenylmethane, m. 193–5°, and 1.66 g. Ph<sub>2</sub>CH. *o*-BrC<sub>6</sub>H<sub>4</sub>OH gives 1.68 g. 3-bromo-4-hydroxytetraphenylmethane, m. 186–7°, and 1.56 g. Ph<sub>2</sub>CH. The other phenols which react give known products. Ph<sub>3</sub>COH, *o*-MeC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>, concd. HCl and AcOH give 4-amino-3-methyltetraphenylmethane, m. 216–7°, which yields a diazonium sulfate, m. 106–7° (decompn.); with EtOH this gives 4-ethoxy-3-methyltetraphenylmethane, m. 143°, also obtained from Ph<sub>3</sub>COH and *o*-MeC<sub>6</sub>H<sub>4</sub>OEt. 4-Chloro-3-methyltetraphenylmethane, pale brown, m. 160°. Ph<sub>2</sub>(PhC<sub>6</sub>H<sub>4</sub>)COH, PhOH, AcOH and H<sub>2</sub>SO<sub>4</sub> give diphenyl-4-hydroxytriphenylmethane, m. 183°. The behavior of a no. of tetraarylmethane derivs. towards H<sub>2</sub>SO<sub>4</sub> and HI-AcOH is reported. The behavior of H<sub>2</sub>SO<sub>4</sub> furnishes addnl. data that the Baeyer-Villiger reaction is reversible.

C. J. WEST

**Action of sulfites upon aromatic amino and hydroxyl compounds. XIII. Extension of the sulfite reaction to resorcinol (synthesis of *m*-hydroxyazo dyes), *p*-phenylene diamine and their derivatives.** HANS TH. BUCHERER and ERICH HOFFMANN. *J. prakt. Chem.* 121, 113–52 (1929); cf. C. A. 20, 1074. —The properties of the mono-SO<sub>3</sub>H acid from *m*-C<sub>6</sub>H<sub>4</sub>(OH)<sub>2</sub> and NaHSO<sub>3</sub>, through the bisulfite, indicate the constitution 2,4-(HO)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>SO<sub>3</sub>H, with NH<sub>4</sub>OH this yields *m*-H<sub>2</sub>NC<sub>6</sub>H<sub>3</sub>(OH)SO<sub>3</sub>H; Ph-NHNH<sub>2</sub> gives *m*-hydroxyazobenzenesulfonic acid, dark red, sol. in H<sub>2</sub>O with a yellow-red color; *p*-AcNHC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>, *p*-H<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>OH and *p*-H<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>(OH)CO<sub>2</sub>H do not react with the acid; *p*-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub> gives *p*-amino-*m*'-hydroxydiphenylaminesulfonic acid, yellow, easily oxidized in the air, stable at 180°, carbonizes at 270°; the diazo soln. is moss-green and gives with R-salt in Na<sub>2</sub>CO<sub>3</sub> a yellow-red dye. NaHSO<sub>3</sub> and *m*-MeC<sub>6</sub>H<sub>3</sub>(NH<sub>2</sub>)<sub>2</sub> form, with splitting off of NH<sub>3</sub>, a sulfite ester, but there is no substitution in the C<sub>6</sub>H<sub>4</sub> nucleus. PhOH does not react with NaHSO<sub>3</sub>, even in the presence of *p*-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub>. 1,4-C<sub>10</sub>H<sub>6</sub>(NH<sub>2</sub>)SO<sub>3</sub>H, *p*-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub> and NaHSO<sub>3</sub> give *p*-aminophenyl-naphthylaminesulfonic acid, green; the diazo soln. couples with R-salt to give a violet dye. 1,5-C<sub>10</sub>H<sub>6</sub>(NH<sub>2</sub>)SO<sub>3</sub>H gives Na *p*-aminophenyl-1-naphthylamine-3-sulfonic acid; the diazo soln. gives a violet dye with R-salt. 1,6-C<sub>10</sub>H<sub>6</sub>(NH<sub>2</sub>)SO<sub>3</sub>H gives *p*-aminophenyl-naphthylamine-6-sulfonic acid, bluish green; *p*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>N<sub>2</sub>X gives a bluish violet dye. 1,2,4-H<sub>3</sub>NC<sub>6</sub>H<sub>3</sub>(OH)SO<sub>3</sub>H and *p*-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub> with NaHSO<sub>3</sub> give *p*-aminophenyl-1-amino-2-naphthol-4-sulfonic acid, green, turning black through oxidation by the air, with the probable formation of an oxazine. C. J. WEST

**Oximes and the Beckmann rearrangement. X. Constitution of oximes.** JAKOB MEISENHEIMER and WALTER THEILACKER. *Ann.* 469, 128–46 (1929); cf. C. A. 23, 2708. —A reply, in support of the Hantzsch-Werner view of the isomerism of oximes, to Ponzio (C. A. 22, 4120). C. J. WEST

**Action of bromine on some hydrazones. II.** R. CIUSA AND P. MEGA. *Gazz. chim. ital.* **58**, 831-40(1928); cf. C. and Vecchiotti, *C. A.* **10**, 2893.—In the previous expts. on the bromination of hydrazones, the formation of  $O_2NC_6H_4CBr:NNHC_6H_4Br_2$  and of  $BrC_6H_4CH:NNHC_6H_4Br_2$  from  $O_2NC_6H_4CH:NNHPh$  and  $PhCH:NNHPh$  resp. was so surprising that further expts. on the confirmation of the differing positions of the 3 Br atoms seemed warranted. Accordingly, the yield of  $p-BrC_6H_4CO_2H$  (I) from the oxidation of  $p-BrC_6H_4CH:NNHC_6H_4Br_2$  (II) was studied. II was obtained under various conditions, but the yields were extremely variable, and large quantities of  $BzOH$  were also formed under all conditions. This suggested that the formula of II was perhaps  $PhCBr:NNHC_6H_4Br_2$  (III) and that I arose from the bromination of  $BzOH$  during oxidation of III. The 2nd formula was confirmed by the fact that by boiling with  $AcONa$  in  $AcOH$ , 1 Br is eliminated quantitatively, and that with  $PhNH_2$ , the product was  $PhC(NHPh):NNHC_6H_4Br_2$  (see below). The action of Br on anisal phenylhydrazine (IV) and on  $p$ -nitrophenylhydrazones was then studied. *Expt.* The oxidation of III was tried under various conditions of temp. and concn., the acid being isolated by filtration, acidification with aq.  $SO_2$ , extn. with  $Et_2O$ , evapn. *in vacuo* and sublimation of the  $BzOH$ . Analysis of the residue showed:  $p-BrC_6H_4CO_2H$ . Alc. III refluxed with  $PhNH_2$  (2 mols.) for 3 hrs., steam-distd., the residual oil washed with boiling water, and crystd. from  $C_6H_6$ , yields  $\omega$ -phenylaminobenzal-2,4-dibromophenylhydrazine, rose-colored, m.  $106^\circ$ . When the alc. mother liquor from the prepn of 2,4- $Br_2C_6H_3NHN:CHPh$  in the previous work was concd. to a small vol., a combd. m.  $171^\circ$ , crystd. It was not identified. Br (21 g.) in cold glacial  $AcOH$  added cautiously to IV (10 g.) in cold glacial  $AcOH$ , filtered, washed with  $EtOH$ , and the residue recrystd. from  $EtOH$  or ligroin, yields  $\omega$ -bromoanisal-2,4-dibromophenylhydrazine, m.  $135^\circ$ . Br (50 g.) in  $AcOH$  (100 cc.) added very slowly to  $PhCH:NNHC_6H_4NO_2$  (25 g.) suspended in  $AcOH$  (200 cc.), with cooling, let stand 24 hrs., filtered, washed with  $AcOH$  and then water and the residue recrystd. from  $AcMe$ , yields the combd. 2,4- $Br_2(O_2N)C_6H_3NHN:CBrPh$  (V), yellow, m.  $171^\circ$ , gives a violet color with alc.  $KOH$ . V (13 g.) refluxed 2 hrs. with  $NaOAc$  (13 g.) and glacial  $AcOH$  (200 cc.), poured into water, filtered and washed with water, yields 9 g. of the *alc. deriv.*, 2,4- $Br_2(O_2N)C_6H_3NHN:CPhAc$  (VI), yellow, could not be purified sufficiently to obtain a definite cryst. form. VI (9 g.) refluxed 2 hrs. in  $EtOH$  (90 cc.) and concd.  $HCl$  (90 cc.), cooled, filtered, the residue dissolved in water,  $NaOAc$  added, filtered, washed and recrystd. from dil.  $EtOH$ , yields 2,4-bromonitrophenylhydrazine (VII), m.  $143^\circ$ , reduces Fehling soln. and  $AgNO_3-NH_4OH$ . VII in alc.  $AcOH$  with  $BzH$  forms, after crystn. from  $EtOH$ , 2,4-bromonitrophenylhydrazone (VIII), dark yellow, m.  $166^\circ$ . Br (6 cc.) in  $AcOH$  added slowly to  $m-O_2NC_6H_4CH:NNHC_6H_4NO_2$  (10 g.) suspended in glacial  $AcOH$  (500 cc.), with cooling, let stand 24 hrs., filtered, and the residue recrystd. from  $AcOH$ , yields the compd.,  $m-O_2NC_6H_4CBr:NNHC_6H_4BrNO_2$  2,4, canary-yellow, m.  $212-3^\circ$ , gives a violet color with alc.  $KOH$ . To prove whether Br is in the *o*-position in VIII, VII was prepd. starting with  $p-O_2NC_6H_4NH_2$  and brominating the  $Bz$  deriv., eliminating the  $Bz$  group with  $KOH$ , diazotizing and reducing with  $SnCl_2$ , for it is known that under these conditions Br enters the *o*-position (cf. *Ber.* **10**, 1709). The nitrophenylhydrazine obtained m.  $143^\circ$  and forms a hydrazone, m.  $166^\circ$ , so that these last 2 compds. are VII and VIII resp. The expts. show that when aromatic hydrazones are brominated, a Br atom always enters the  $\omega$ -position, while the other Br atoms enter the hydrazinic  $C_6H_5$  nucleus. The expts. are closely related to recent expts. of Humphries, Bloom and Evans (*C. A.* **17**, 3170; Chattaway and Walker, *C. A.* **19**, 2332, 2938-9; Vanghelovitch, *Bull. soc. chim. Roumanie* **7**(1926) and *C. A.* **22**, 3640). C. C. DAVIS

**Industrial methods of benzaldehyde manufacture.** P. SHORIGIN, I. KIZBERG, N. TROITZKII AND E. SMOLYANINOVA. *J. Chem. Ind. (Moscow)* **6**, 258-60(1929).—The method of toluene oxidation by  $MnO_2$  was investigated by varying the temp., the  $H_2SO_4$  concn., the proportions of the mixt. and by trying the action of accelerators. After about 100 expts. it was found that the most favorable conditions are: temp.  $18-19^\circ$ ,  $H_2SO_4$  concn. 65%, ratio of toluene to that of  $MnO_2$  4:1. Under those conditions the  $BzH$  yield reaches 55-6% of theory (calc. on the active  $MnO_2$ ). Among catalysts, a small quantity of  $HNO_3$  was found to have a slight accelerating action, whereas  $CuSO_4$  and  $KI$  were found to be without effect. To avoid the use of the expensive  $MnO_2$ , the product of heating powd. pyrolusite with 10-25%  $NaOH$  in an autoclave at  $156-8^\circ$  under 6-6.5 atm. was tried; the  $BzH$  yield in this case reached only 14%. Neg. results were also obtained by operating, instead of with  $MnO_2$ , with *pyrolusite* passed through a colloidal mill. *Walker's method of BzH prepn. by oxidiz. of toluene vapors by atm. O in presence of  $V_2O_5$  as catalyzer* was also investigated. The catalyzer

consisted of pumice contg. on its surface 33%  $V_2O_5$ . Ten expts. were made, each time 100 g. toluene being passed during 4–6 hrs. with an excess of air, the rate of passing the latter being 120 l. per hr. The most favorable temp. is 390–410°. The BzH yield is but 4–5% of the wt. of toluene, while BzOH (2–3%) and anthraquinone (4–5%) are also obtained simultaneously, and 56% toluene is obtained unchanged and 30–35% of it is completely burned to  $CO_2$  and  $H_2O$ . As both these processes are unsatisfactory, expts. on BzH prepn. from toluene through benzyl chloride were undertaken. By chlorinating toluene vapors in presence of a 4–5000 c. p. elec. lamp crude  $PhCH_2Cl$  is obtained which contains 30% unchanged toluene. This crude product was treated for 6 hrs. with 10% NaOH in a closed app provided with a stirrer and a reflux condenser. After this sapon. operation the alky. of the soln. corresponded to 2% NaOH. On cooling, the reaction mixt. sepd. in 2 layers which, as they both contained  $PhCH_2OH$ , were treated together for oxidation by being introduced in a mixt. heated to 40° of bleaching lunc suspended in  $H_2O$  and a 30% excess of  $Na_2CO_3$  soln. The temp. rose spontaneously to 60° and a mixt. of BzH and BzOH was obtained. 40–60° are the most favorable temp. conditions; the yield of the BzH-BzOH mixt. is 35% of the wt. of the crude  $PhCH_2Cl$  taken, the accompanying PhMe being unaffected during the treatment. This seems to be a good industrial process; it gives BzH of very good quality. BzH may also be manufd. by catalytic oxidation of either  $PhCH_2OH$  or  $PhCH_2Cl$ . 100 g.  $PhCH_2OH$  gave 60 g. pure BzH (51% yield) and 1.5 g. BzOH when its vapor mixed with an excess of air was passed for 4.25 hrs. at 400–480° over pumice contg. 33%  $V_2O_5$ . 30 g.  $PhCH_2Cl$  mixed with 50–80 g.  $H_2O$  vapor and 160 l. air and passed for 1 hr. at 360–380° through a tube 25 mm. in diam. and 97 cm. long contg. the pumice- $V_2O_5$  catalyst gave a BzH yield of 74% and a BzOH yield of 10%. (When the operation is effected at 310–320° the BzH yield is only 15%, and at 450–460° it is 32%.)  $PhCH_2Cl \rightarrow PhCH_2OH + HCl$ ;  $PhCH_2OH \rightarrow BzH \rightarrow BzOH$ . Anthraquinone formation is not observed, but a few g. of black tar is deposited on the catalyst. The catalyst may be regenerated by calcination in an Fe dish followed by heating in a porcelain dish with a small quantity of  $HNO_3$ , evapn. on a water bath and ignition in a test tube at first in a current of air, then in a current of  $O_2$ . The prepn. of the catalyst from the black tech. product contg. 73%  $V_2O_5$  consisted in pulverizing it, melting with  $KNO_3$  and  $Na_2CO_3$ , extg. with  $H_2O$ , filtering and pptg. with HCl; the ppt. was washed, made into a paste with  $H_2O$  and treated with pea-size pieces of pumice which were previously calcined. The treated pumice was then dried on a water bath and calcined in a test tube at 450° in a current of air and  $O_2$ . The catalyst obtained contained 30–40%  $V_2O_5$ .

BERNARD NELSON

**Isomerism of the oximes. XXXIV.** The dissociation constants of isomeric oximes and their influence on the production of the isomerides in alkaline solution. OSCAR L. BRADY and NAVNITLAL MOHANLAL CHOKSHI. *J. Chem. Soc.* **1929**, 946–51; cf. C. A. **22**, 1968.—The cond. method cannot be used for those oximes which are very weak acids and sparingly sol. in  $H_2O$  owing to the sepn. of the solid oxime when the Na salt dissociates hydrolytically. The method of Farmer (*J. Chem. Soc.* **79**, 863 (1901)), depending upon the measurement of the degree of hydrolysis of the Na salt as detd. by the distribution coeff. of the oxime between aq. NaOH and an org. solvent, was employed. The following values are reported ( $K_a \times 10^{11}$ , for some 2 values are given):  $\alpha$ -*o*-methoxybenzaloxime, 1.45, 1.60;  $\alpha$ -*m*- $NO_2$  deriv., 7.10, 6.69;  $\alpha$ -*p*- $NO_2$  deriv., 10.93;  $\alpha$ -*p*-dimethylamino deriv., 0.55, 0.57;  $\alpha$ -furfuraldoxime, 1.46, 1.33;  $\beta$  deriv., 1.57, 1.43;  $\alpha$ -*o*-methoxycinnamaloxime, 1.61, 1.53;  $\beta$ -deriv., 0.45, 0.44;  $\alpha$ -*p*-nitrobenzophenone oxime, 1.21, 1.59;  $\beta$ -deriv., 3.37; benzophenone oxime, 0.48, 0.53; acetophenone oxime, 0.33. These results with exptl. work on the production of oximes show that if the dissoen. const. are widely different, only the oxime with the higher const. is obtained, whereas if they are nearly the same, both isomeric oximes are formed.

C. J. WEST

**Arylidene-2,4-diphenylsemicarbazones from aldophenylhydrazones and phenyl isocyanate.** GAETANO MINUNNI and SALVATORE D'URSO with SILVIA GUGLIELMINO, PIETRO SALANITRO, DOMENICO TORRISI and MARIO VASTA. *Gazz. chim. ital.* **58**, 808 20(1928).—In syntheses of nitrogenated heterocyclic compds., it was necessary to use, as a starting point, substances of the general type  $RCH:NNR'CONHR''$ . Accordingly the prepn. of the latter by the reaction:  $RCH:NNHR' + CONR'' \rightarrow RCH:NNR'CONHR''$ , was studied, a reaction which was investigated by Busch and Walter (cf. *Ber.* **36**, 1357(1903)), who did not succeed in obtaining the desired products. In spite of this, the present paper shows that phenylhydrazones of BzH and other aromatic aldehydes react even at room temp. with  $PhNCO$  (I) to give good yields of the corresponding arylidene-2,4-diphenylsemicarbazones. I (3.5 g.) refluxed 3 hrs.

with  $\text{PhCH:NNHPh}$  (II) (5 g.) in anhyd.  $\text{C}_6\text{H}_6$  (25 cc.), the  $\text{C}_6\text{H}_6$  removed by distn., the residue ground with EtOH, filtered, washed with EtOH, and the residue crystd. from boiling EtOH, yields 4 g. of  $\text{PhCH:NNPhCONHPh}$  (III), m.  $174-5^\circ$  (cf.  $173^\circ$  of Busch and Walter, *Ber.* 36, 1357(1903)). From the EtOH used in grinding the crude reaction product (*loc. cit.*) was obtained a very small quantity of  $(\text{PhHN})_2\text{CO}$ , I (3.5 g.) let stand at room temp. with II (5 g.) in anhyd.  $\text{C}_6\text{H}_6$  (25 cc.) for 15 days with frequent agitation, and treated as before, yields 4.3 g. of III, m.  $172-3^\circ$ . From the alc. mother liquors were obtained very small quantities of 2 secondary products, a yellow compd., m.  $194-6^\circ$ , and a canary-yellow compd., m.  $175-88^\circ$ , which could not be freed of impurities. III is easily reduced, e. g., with Zn and glacial HOAc it forms  $(\text{PhNH})_2\text{CO}$ . The dild. mother liquor from the latter reaction, made alk. with  $\text{NH}_4\text{OH}$ , concd., extd. with  $\text{Et}_2\text{O}$  and the ext. evapd., yields on recrystn. from hot water an unidentified compd., m.  $116-8^\circ$ . The transformation of arylidene-2,4-diarylsenicarbazones to 2,4-diarylsenicarbazides was then investigated, because the latter should be of value in the synthesis of nitrogenated heterocyclic compds. Recent expts. with  $\text{PhHNNH}_2$  (IV) compds. contg. arylidene groups indicated that III could be transformed by  $\text{PhHNNH}_2$  according to the reaction:  $\text{III} + \text{IV} \rightarrow \text{H}_2\text{NNPhCONHPh}$  (V) +  $\text{PhCH:NNHPh}$  (VI). Expts. showed that the benzylidene group was split with great ease, but V could not be isolated in a pure state. Thus, heated at  $150^\circ$ , III and IV yield an amorphous paste which, digested in hot dil. HCl, the solidified product dissolved in boiling EtOH, cooled and recrystd. in the same way, gives a product m.  $125-45^\circ$ . III (5 g.) and IV (2 g.) refluxed in glacial AcOH (10 cc.) for several hrs., cooled, yields VI, but no V could be isolated.  $o\text{-O}_2\text{NC}_6\text{H}_4\text{CH:NNHPh}$  (VII) (2 g.) and I (1.2 g.) refluxed in anhyd.  $\text{C}_6\text{H}_6$  (50 cc.) for 3 hrs., the mother liquid coned and allowed to evap., yields a small quantity of a substance, m.  $178-81^\circ$ , and a mixt., m.  $135-70^\circ$ . I and VII heated at  $120^\circ$  do not react well, while at  $150^\circ$  the mixt. resinifies almost completely. But I and VII (equal wts.) heated 3 hrs. at  $130^\circ$ , digested in hot EtOH, filtered, and the residue purified by further treatment with EtOH, yields *o*-nitrobenzylidene-2,4-diphenylsemicarbazone,  $o\text{-O}_2\text{NC}_6\text{H}_4\text{CH:NNHPhCONHPh}$  (VIII), lustrous yellow, m.  $190-2^\circ$  (decompn.). I and VII (equal wts.) let stand in a little  $\text{C}_6\text{H}_6$  for 20 days, filtered, the residue washed with EtOH, recrystd. from boiling EtOH, gives about the same yield of VIII as by the hot method (*loc. cit.*). VIII heated several hrs. on a water bath with glacial AcOH and Zn dust, filtered hot, the filtrate treated with water, and the ppt. recrystd. from boiling EtOH, yields  $(\text{PhNH})_2\text{CO}$ .  $m\text{-O}_2\text{NC}_6\text{H}_4\text{CH:NNHPh}$  and I (equal wts.) heated 6 hrs. in  $\text{C}_6\text{H}_6$  yield *m*-nitrobenzylidene-2,4-diphenylsemicarbazone (IX), m.  $206-8^\circ$  (decompn.). The reaction is more rapid without solvent, e. g., heated at  $130-5^\circ$  for 2.5 hrs., and the product purified with EtOH. As with VIII, reduction of IX with Zn and glacial AcOH forms  $(\text{PhNH})_2\text{CO}$ . With  $p\text{-O}_2\text{NC}_6\text{H}_4\text{CH:NNHPh}$  (X), the reaction is relatively slow. I (1.3 g.) and X (1 g.) refluxed in  $\text{C}_6\text{H}_6$  (15 cc.) for 9 hrs. yield 0.6 g. of *p*-nitrobenzylidene-2,4-diphenylsemicarbazone, m.  $198-200^\circ$ . More satisfactory results are obtained without  $\text{C}_6\text{H}_6$ . X (5 g.) and I (4 g.) heated for 5 hrs. at  $150^\circ$ , digested in EtOH, filtered, the residue refluxed with EtOH, filtered, the residue suspended in boiling EtOH,  $\text{C}_6\text{H}_6$  added until soln. is complete, cooled, and the ppt. recrystd., yields 4.5 g. of *p*-nitrobenzylidene-2,4-diphenylsemicarbazone, rose-yellow, m.  $199-201^\circ$ . I (2.6 g.) and piperonalphenylhydrazone (XI) (5 g.) in anhyd.  $\text{C}_6\text{H}_6$  (25 cc.) let stand 3 weeks at room temp. with daily agitation, filtered, and purified with EtOH, yields 92% of *p*-nitrobenzylidene-2,4-diphenylsemicarbazone (XII), lustrous, yellowish, m.  $169-9.5^\circ$  (decompn.). I (2.6 g.) and XI (5 g.) in anhyd.  $\text{C}_6\text{H}_6$  (50 cc.) refluxed 3 hrs., yields after purification from EtOH, 5.3 g. of XII.

C. C. DAVIS

New syntheses of nitrogenated heterocyclic nuclei. III. Triaryl derivatives of 1,2,4-triazoles from arylidene-2,4-diphenylsemicarbazones. GAETANO MINUNNI AND SALVATORE D'URSO (WITH SILVIA GUGLIELMINO, PIETRO SALANITRO, DOMENICO TORRISI AND MARIO VASTA). *Gazz. chim. ital.* 58, 820-31(1928).—The development of a general method for the prepn. of arylidene-2,4-diarylsenicarbazones (cf. preceding abstr.) gave an opportunity to study the possibility of prepg. various isocyclic and heterocyclic compds. The synthesis of 1,2,4-triazoles, thus:  $\text{RCH:NNR'CONHR''}$

$\xrightarrow{-\text{H}_2}$   $\text{RC:N.NR'.CO.NR''}$ , was first studied, a reaction already used under in-

convenient conditions by Busch and Walter (cf. *Ber.* 36, 1360(1903)). The chief difficulty was to find a suitable oxidant, but since the H atoms to be eliminated from compds.  $\text{RCH:NNR'CONHR''}$  are analogous to those in aldo-phenylhydrazones where the H atoms have been successively oxidized out by  $\text{AmNO}_2$  (*C. A.* 22, 238),

it was considered that  $\text{AmNO}_2$  was the best choice. The expts. described in the present paper show that this is a very satisfactory reagent, all the semicarbazones tested being transformed into 1,3,4-triaryl-1,2,4-triazolones.  $\text{PhCH:N.NPhCONHPh}$  (I) reacts easily in  $\text{C}_6\text{H}_6$  at room temp., whereas  $o\text{-O}_2\text{NC}_6\text{H}_4\text{CH:N.NPhCONHPh}$  (II),  $m\text{-O}_2\text{NC}_6\text{H}_4\text{CH:N.NPhCONHPh}$  (III),  $p\text{-O}_2\text{NC}_6\text{H}_4\text{CH:N.NPhCONHPh}$  (IV) and  $\text{O.C}_6\text{H}_4\text{O.C}_6\text{H}_4\text{CH:N.NPhCONHPh}$  (V) react in soln. extremely slowly, but when

boiled in  $\text{AmNO}_2$  for several hrs. without any other solvent they give fair yields of the triazolones. The latter can be easily crystd. and thus purified. I does not react with  $\text{HgO}$ , either in  $\text{Et}_2\text{O}$  or in  $\text{CHCl}_3$ , nor with  $\text{AmOH}$  in  $\text{Et}_2\text{O}$  even after heating several hrs.; but with  $\text{PhMe}$  or better with  $\text{C}_6\text{H}_6$  the reaction proceeds readily. I (5 g.), anhyd.  $\text{C}_6\text{H}_6$  (30 cc.) and  $\text{AmNO}_2$  (10 g.) refluxed at least 6 hrs., let stand several hrs., filtered, washed with  $\text{EtOH}$ , and the residue recrystd. from boiling  $\text{EtOH}$ , yield 40% of  $\text{PhC:N.NPh.CO.NPh}$  (VI), m.  $221.5\text{--}2.0^\circ$  (cf.  $215\text{--}6^\circ$  of Busch and Walter, *loc.*

*cit.*). A fair yield is obtained after many days' standing at room temp., using an excess of  $\text{AmNO}_2$ . I (2 g.) boiled in  $\text{AmNO}_2$  (5 g.) for 4 hrs. and the product purified with  $\text{EtOH}$ , yields 0.8 g. of VI, which is therefore a good method of prepn. With II a large excess of  $\text{AmNO}_2$  is necessary, or the yield is low. II (2 g.) refluxed 7 hrs. with fresh  $\text{AmNO}_2$  (15 g.), cooled, filtered, washed with  $\text{Et}_2\text{O}$ , the filtrate evapd. *in vacuo*, a little  $\text{Et}_2\text{O}$  mixed with the residue, allowed to evap. until a cryst. ppt. forms, filtered, the residue combined with the previous one, boiled 3 hrs. in  $\text{EtOH}$  with animal charcoal, filtered, the filtrate concd., and the ppt. recrystd. from  $\text{EtOH}$ , yields 1,4-diphenyl-3-*o*-nitrophenyl-1,2,4-triazolone (VII), m.  $135\text{--}7^\circ$  (decompn.). VII (2 g.) heated with Zn dust (5 g.) and glacial  $\text{AcOH}$  (50 cc.) on a water-bath for 2 hrs., filtered, the filtrate poured into a large vol. of water, filtered, washed with water, boiled in  $\text{EtOH}$  with animal charcoal, filtered, concd., and recrystd. several times from boiling  $\text{EtOH}$ , yields 1,4-diphenyl-3-*o*-aminophenyl-1,2,4-triazolone, m.  $192.5\text{--}3.5^\circ$  (decomp.). A trace of a secondary product, m.  $244\text{--}7^\circ$ , was obtained. Very little reaction took place when III (2 g.) was heated with  $\text{AmNO}_2$  (5 g.) in  $\text{PhMe}$  for 4 hrs. However, III (2 g.) refluxed in  $\text{AmNO}_2$  (30 g.) for 8 hrs., let stand several hrs., filtered, the residue mixed with  $\text{EtOH}$ , filtered, washed with  $\text{EtOH}$  and recrystd. repeatedly from boiling  $\text{EtOH}$ , yields 50% of 1,4-diphenyl-3-*m*-nitrophenyl-1,2,4-triazolone, lustrous yellow, m.  $198\text{--}200^\circ$ . IV (2 g.) refluxed in  $\text{AmNO}_2$  (20 g.) for 8 hrs., cooled, filtered, washed with  $\text{EtOH}$  and the residue recrystd. from boiling  $\text{EtOH}$ , or better from a mixt. of  $\text{EtOH}$  and  $\text{C}_6\text{H}_6$ , yields 50% 1,4-diphenyl-3-*p*-nitrophenyl-1,2,4-triazolone (VIII), lustrous yellow, m.  $193\text{--}4^\circ$ . VIII (2 g.) heated with Zn dust (10 g.) and glacial  $\text{AcOH}$  (100 cc.) for 4 hrs., filtered hot, the filtrate cooled, refiltered, the filtrate concd. *in vacuo*, poured into a large vol. of water, let stand several hrs., filtered, washed with water, and the residue purified by suspension in hot water, addn. of  $\text{EtOH}$  to complete soln. and cooling, yields 85% of the compd.  $\text{C}_{20}\text{H}_{17}\text{N}_3$ , which may be the triphenyltriazole  $\text{PhC:N.NPh.CH}_2\text{.NPh}$ . V (2 g.) heated with  $\text{AmNO}_2$  (15 g.) for 10 hrs. on a water

bath, the reaction mixt. distd. *in vacuo* on a water bath, the residue recrystd. repeatedly from  $\text{EtOH}$ , yields 1,4-diphenyl-3-piperonyl-1,2,4-triazolone, which m.  $169\text{--}70^\circ$  and has a greasy feeling.

**Isomerism relationships in the chalcone series.** VI. Relations between polymorphism and ethylene stereoisomerism. C. WEYGAND (WITH E. BAUER AND H. HENNIG). *Ber.* 62B, 562-73 (1929); cf. *C. A.* 22, 953.—It seems now to be practically unanimously agreed by chemists working in the field of polymorphism of org. compds. that the boundary between "phys." and "chem." isomerism, insofar as it can be detd. at all with exactness, does not coincide with the boundaries of the classical doctrines of isomerism. Recently W. attempted to group the long known, well defined forms of dibenzoylmethane enol (I) and its *o*-Et (II) and *o*-Me ethers (III) in such a way as to indicate that in this "family" of polymorphic modifications the relationship between certain members of the 3 "series" should be closer than that with other members. The original scheme has had to be modified in certain minor respects and now stands as follows:

$\beta$ -Methoxychalcone	m.	$65^\circ$	$78^\circ$	$81^\circ$	$?$	(Series III)
$\beta$ -Ethoxychalcone		$63^\circ$	$74^\circ$	$78^\circ$	$81^\circ$	(Series II)
$\beta$ -Hydroxychalcone		$?$	$73^\circ$	$78^\circ$	$81^\circ$	(Series I)
Member No.		1	2	3	4	

All the forms capable of existence of a no. of closely related substances are designated

a "family," and all the (hylotropic isomeric) forms of an individual, structurally homogeneous substance as a "series"; in the above scheme the members of 2 or more series standing immediately under each other are corresponding members, and such members should correspond very closely to each other in their fine mol. structure, or at least should be much more closely related in this respect than non-corresponding members. As to the individual members of the above family, some new observations have been made. W. had formerly believed that his 73°-form (m. 72-3°) of I was identical with the 70-1°-form, which had also been discovered independently by Dufrasse and Gillet who obtained it by aseptic crystn. of the ordinary 78°-form from hot MeOH. W. has since found that it can be obtained from solns. of both ordinary I and of BzC : CPh in concd. H<sub>2</sub>SO<sub>4</sub> allowed to absorb H<sub>2</sub>O from the air. The 73°-form, which is formed on spontaneous solidification of the undercooled melt of I, can, contrary to the 71°-form, be kept practically as long as desired, is not oversensitive to germs of the stable form and is therefore distinctly different from it. The scheme has been constructed on the basis of observations of various kinds. The 1st criterion is furnished by the m. ps. In this respect the present scheme is more satisfactory than the earlier one; there are no longer any gaps in the middle and the differences between the m. ps. of corresponding members are remarkably uniform. No place has yet been found for the very unstable 71°-form. Stability relationships might be thought to be a 2nd criterion, but such is not the case; the scheme is intended to indicate only that corresponding members have the same or similar fine mol. structures. The rule that *trans*-forms are often more stable than the *cis*-forms has a real meaning only when 2 of the H atoms in a C<sub>2</sub>H<sub>4</sub> mol. are substituted; when, as in the above family, 3 of the H atoms are substituted, it is already quite arbitrary which of the structures BzCH and BzCH

is considered as the *cis*-form. Nevertheless, the stability relationships in this family are such as to justify rather than discredit the scheme. In Series I and II the 3rd members are stable, the 4th metastable. The first 2 of Series II and the 2nd of I are metastable. In Series III the relations between the 1st and 3rd members are such that it cannot reliably be stated which is the unconditionally stable form. The 2nd member is metastable and corresponds to the 2nd member of Series I and II. The 3rd criterion is purely chem and requires the greatest caution in its application. The postulate that members of Series II and III when hydrolyzed with acids should yield corresponding members of Series I would require, when applied to C<sub>2</sub>H<sub>4</sub> stereoisomers, that in mild reactions *cis*- or *trans*-forms always give derivs of the same configuration. Although this is generally true, recent observations point to the need of caution in this direction. In the above family, the 81°-form of II gives the 81°-form of I and the 81°-III and 78°-II give the corresponding 78°-I. The 65°-III, in the absence of every outside influence, does not give the corresponding (as yet unknown and perhaps non-existent) I but the next adjacent member (metastable 73°-form). The 63°-II gives the non-corresponding stable 78°-I. The above postulate may be reversed: mild methylation or ethylation of a member of Series I should give a corresponding deriv. of Series III or II. This has been verified with the 78°-I treated with CH<sub>3</sub>N<sub>2</sub> or M CHN<sub>2</sub>. A 4th postulate is that corresponding forms should be crystallographically similar to each other. The 65°- and 81°-III form different melts and solns.; neither has a seeding influence on the melt of the other; they are readily transformable into each other (by crystn. from MeOH, action of sunlight or heating with traces of acid in alc., heating in the dry state); the same equil. point is reached from either direction; the m. p. of mixts. is considerably depressed. While the two III thus behave like true chem. individuals of the kind of numerous C<sub>2</sub>H<sub>4</sub> stereoisomers, the corresponding 63°- and 78°-II stand distinctly on the boundary between isomerism and polymorphism. The more sol., metastable form can be extd. from the conglomerate with petroleum ether; they show mixed m. ps. but no depression; an undercooled melt of one can be made to solidify in the other form by seeding and the solid 63°-changes into the 78°-form spontaneously or in contact with the latter. Crystallographic comparisons were not made by measuring individual crystals but by observing the mechanism of solidification of melts and by qual. comparison of the polarization tones. The 78°-II and 81°-III grow out from an undercooled drop of their melts in fungus-like forms, while the 63°-II and 65°-III yield radiating flat formations differing but slightly from the drop in shape. The same similarity to each other of the members of each pair and difference from the members of the other pair is found in the characteristic polarization tones and in the behavior of the advancing zone of solidification toward air bubbles imprisoned in the melt. It had been concluded, from the

behavior toward picric acid, that *p*'-ethyl- and *p*'-propylchalcone (known in only 1 form) did not belong to the stable  $\alpha$ -form but to a metastable form; on observing their undercooled melts under the microscope, the authors now find that the 2 substances behave quite alike on cooling and entirely differently from *p*'-methoxychalcone, which solidifies only in the  $\alpha$ -form. The solidified melts of the 63°-III and 63°-II are not so similar to each other as those of the higher melting pair; possibly the process of solidification of the II melts, seeded with the 63°-form, is especially complicated because they contain different forms. In the transformation of the higher into the lower melting forms by heating, the seeding effect of the solid phases on the undercooled melts can be observed immediately after fusion with the II but only after about 1 hr. with the III, *i. e.*, equil. between several forms is probably established very rapidly with the II while the III preserves its identity unchanged for a time. The same may be true in solid, which would explain why the 65°-III gives a metastable I on hydrolysis while the 63°-II does not. C. A. R.

**Isomerism relations in the chalcone series.** VII. A natural system of the polymorphous forms of *p*'-methylchalcone. C. WEYGAND AND H. BAUMGÄRTEL. *Ann.* **469**, 225-56 (1929); cf. preceding abstr.—Seven forms of *p*'-methylchalcone, m. 74.5°, 56.5°, 55.5°, 54.5°, 45.5°, 48°, and 44.5°, have been observed on a cover glass. The original should be consulted for details of the exptl. methods and the theoretical discussion of the relations of these forms. C. J. WEST

**Problem of the constitution of 1,3-diketones.** II. Tendency to enolize and direction of the enolization. C. WEYGAND AND H. BAUMGÄRTEL. *Ber.* **62B**, 574-9 (1929), cf. *C. A.* **22**, 1580.—It was shown in the 1st paper that the keto-enols  $\text{RC}_6\text{H}_4\text{C}(\text{OH})\text{CHCOPh}$  and  $\text{RC}_6\text{H}_4\text{COCH}_2\text{C}(\text{OH})\text{Ph}$  corresponding, formally, to the unsym. 1,3-diketones  $\text{RC}_6\text{H}_4\text{COCH}_2\text{COPh}$  are not formed by hydrolysis of their *o*-Me ethers and it is therefore a question to which, if any, of the enolization products of 1,3-diketones a definite structure can be assigned. Scheiber and Herolds' method of detg. the structure of enols did not shed any light on the problem in this case; not only did the solns. of 4 preps., which in the solid state were to all appearances homogeneous keto-enols, always yield the cleavage products of the 2 theoretically possible enol forms but the substituted dibenzoylmethanes behaved towards  $\text{O}_3$  as if they were chiefly dienols,  $\text{RC}(\text{OH})\text{:C:C}(\text{OH})\text{R}'$ , whereas their polymorphism phenomena show quite definitely that they are  $\beta$ -hydroxychalcones (see preceding abstrs.). While the enolization relationships in purely aromatic substituted 1,3-diketones are thus extraordinarily obscure, they are strikingly simple, in a certain respect, in the homologs of  $\text{CH}_2\text{Ac}_2$  (I) where the relation between the tendency to enolize and the direction of enolization surmised by Meyer and proved in all its essential points by Scheiber and Herold is shown in all clearness by a homologous series contg. many members. The direction of the enolization, however, is surprising. Since it had hitherto been generally assumed that there is an intimate relationship between the enolization tendency of an acyl group and the strength of its corresponding  $\text{CO}_2\text{H}$  acid it might have been expected that in decyloacetone (II) the Ac group would be chiefly enolized and further that it would be less enolized than in I with its two Ac groups. As a matter of fact, the % of enol in the equil. mixts. of the *acylacetones* increases in the order: I, 76.4; propionyl (III), 80.2; butyryl (IV), 83.6; heptyl (V), 93.9; II, 100.2. The  $\text{O}_3$  cleavage which, because of the favorable soly. relations, was carried out in the extraordinarily indifferent  $\text{EtCl}$ , yielded products corresponding entirely to this unexpected behavior. While I gave the characteristic  $\text{AcCHO}$  (VI), isolated as the osazone, III yielded only smeary ppts. (presumably mixts. of the osazones of VI and  $\text{EtCOCHO}$ ); IV gave chiefly an only product, together with some VI and much  $\text{PrCO}_2\text{H}$  (*i. e.*, the cleavage products of  $\text{PrC}(\text{OH})\text{:CHAc}$ ); V yielded much VI with some enanthic acid, and II gave impure VI and a large amt. of capric acid. When the C chain is branched the enolization relationships change at once;  $\text{Me}_2\text{CHCOCH}_2\text{Ac}$  (VII) at equil. contains only about 60% enol. These simple results, however, did not seem to agree with observations made in connection with the synthesis of the diketones (through their Cu salts). On distn. *in vacuo* (not under atm. pressure) of the III, IV and V liberated from the crude Cu salts, they yielded 2 distinct fractions which gave Cu salts of different m. ps.; W. and B. are inclined to believe that this is a case of finer "phys." isomerism of the type observed by Harries with mesityl oxide. III gave fractions  $b_{12}$  43° and 45°, IV fractions  $b_{11}$  57-61° and  $b_{12}$  64-8° yielding Cu salts, m. 164-5° and 161-2°, and V fractions  $b_{12}$  108° and  $b_{12}$  114-8°, whose Cu salts m. 125-6° and 122-3°. II,  $b_{12}$  150-2° (Morgan and Holmes give 180° under 11 mm.), m. 124-7°; Cu salt, m. 110° (M. and H., 114°). VII,  $b_{12}$  67-71°. C. A. R.

The green forms of the *p*-dihydroxydibenzal ketones. D. VORLÄNDER AND OTTO KOCH. *Ber.* 62B, 534-40 (1929).—Green forms of (*p*-HOC<sub>6</sub>H<sub>4</sub>CH : CH)<sub>2</sub>CO (I) and of *p*-dihydroxydibenzal cyclopentanone and -hexanone have been obtained by Zincke and Mülhausen and by Vörländer by decomp. the dark violet or blue-black HCl or HBr salts of the ordinary forms with cold H<sub>2</sub>O and washing until the washings no longer give a turbidity with AgNO<sub>3</sub> and the green residues are halogen-free (Beilstein test). These green forms can be recrystd. from cold EtOH-H<sub>2</sub>O but change in time into the yellow (orange- or brown-yellow) forms. A particle of the green I forms in 100-300 parts of cold Ac<sub>2</sub>O a dark violet-blue soln. whereas the ordinary form gives only a light yellow soln. so there can be no doubt that the green forms are capable of independent existence in soln. as well as in the solid state. Further expts. with I and with divanillalacetone (II) have led to results in a direction differing materially from that to which the earlier work was believed to point. The green "halogen-free" form of I must as a matter of fact always contain a small amt. of a strong acid to appear green; the Beilstein test is much less sensitive than is generally assumed. A green I which on decompn. with fused purest, halogen-free NaOH shows 0.11% HCl hardly gives the test when carried out in the usual way and only when the ketone is concd. from a satd. Me<sub>2</sub>CO soln. on the porous CuO does the flame test become distinctly visible; even this modified form of the test gave a negative result with the same green prepn. purified by crystn. from EtOH-ice H<sub>2</sub>O until the HCl content was only 0.04%. By this purification the color of the I was changed to yellow-green and when the greenish tone completely disappears as the result of further crystn. the prepn. no longer contains any HCl. If the dark olive-green alc. soln. of the freshly prepd. green I is treated with cold alc. AgNO<sub>3</sub> its green color disappears much more quickly than that of a soln. in alc. without AgNO<sub>3</sub> (0.5 as compared with 5 hrs.). In the change of the green into the yellow form there is not only a splitting off of the minute traces of HCl but a change from the colloidal state of the green into the coarse cryst. state of the yellow form which often is no longer turned green by traces of HCl. Thus the C<sub>6</sub>H<sub>6</sub> soln. of the yellow I is not turned green by traces of HCl and that in much Ac<sub>2</sub>O does not become violet-blue, but a H<sub>2</sub>O suspension is turned greenish by dil. HCl. The Me<sub>2</sub>CO soln. of the green form changes from blue through brown to yellow and under the ultramicroscope shows scarlet disks paling to orange; the abs. alc. soln. is green with light, faintly reddish disks and after 2 hrs. is yellow-greenish with light green disks; on the other hand, solns. of the yellow form in C<sub>6</sub>H<sub>6</sub> or C<sub>4</sub>H<sub>8</sub> with a trace of HCl are faintly yellow and almost optically void. The difference in dispersion between the green and yellow forms accounts for a host of observations already reported but without being able to explain them (decrease in soly. of the green form on standing, its more rapid acetylation, its apparently greater soly. in Ac<sub>2</sub>O, the dark violet-blue color of its soln. in Ac<sub>2</sub>O, etc.). These phenomena are very complicated and are by no means to be ascribed entirely to differences in the degree of dispersion but it may at least be stated that the green forms consist of solid colloidal solns. of small amts. of colored acid addn. products in yellow crystals. A surprising time reaction can be observed when the dark black HCl salt is dissolved in cold dil. alkali and then treated with excess of dil. AcOH. If the acid is added immediately a green ppt. is formed but if the alk. soln. is allowed to stand a few min. before adding the acid a yellow ppt. is obtained. The free green or yellow I, on the other hand, are pptd. from alk. soln. only in yellow form, regardless of the length of time the alk. soln. has stood. These yellow ppts. are at once colored greenish by dil. HNO<sub>3</sub> and such greenish ppts. are always obtained from alk. solns. with excess of dil. HCl. In other words, in an alk. soln. of the ketone-HCl there occurs a time reaction in which the alkali reacts with the HCl of the ketone-HCl. Cl ions have nothing to do with this time reaction; addn. of much KCl or NaCl to the alk. soln. and subsequent acidification with AcOH produces no green ppt. or time phenomenon, whereas these results are obtained by turning the ketone green with concd. HCl, then dissolving it in alkali and reprecip. it with AcOH. The key to these phenomena is probably the strongly colloidal condition of the alk. aq. solns., all of which, whether prepd. from the yellow or the green forms, show bright, intensely red light disks under the ultramicroscope. In the freshly prepd. alk. solns. of the ketone-HCl, a part of the HCl adsorbed on the colloidal ketone remains unneutralized for a varying length of time in the presence of the excess of OH ions and produces a green ppt. with AcOH, but as soon as it has been completely neutralized AcOH can no longer form a green ppt. V. and K. can find no other explanation for their results. The blue-black HCl salt of II, freshly pptd. from alc. with HCl, contains up to 3 mols. HCl, after 12 hrs. *in vacuo* 2 mols., after 3 days hardly more than 1 mol., when it is dark green, it no longer fumes and is quite stable. The green form of II, which always con-

tains traces of acid, is obtained by shaking the freshly prepd. blue-black HCl salt with cold  $\text{H}_2\text{O}$ , the yellow form by pptn. of the blood-red, aq. alk. soln. of the green form with AcOH. The yellow II, recrystd. from  $\text{EtOH-H}_2\text{O}$ , contains 1 mol.  $\text{H}_2\text{O}$  and m.  $118^\circ$ ; after drying *in vacuo* over  $\text{P}_2\text{O}_5$  or recrystg. from  $\text{C}_6\text{H}_6\text{-PhMc}$ , it m.  $143^\circ$ . The 2 forms do not differ appreciably in soly. The  $\text{C}_6\text{H}_6$  soln. of the anhyd. yellow form is changed permanently green by traces of moist HCl, whereas in the absence of moisture a brown-red color is formed. The solid anhyd. yellow form can stand 45 mins. in dry HCl before a green color becomes distinctly visible, whereas the hydrated II under the same conditions becomes superficially green in 1 min. and in aq. suspension is at once turned green by 5–10% HCl. The green color produced depends on the concn. of the aq. HCl; besides HBr and HCl, other strong acids (but not AcOH) in  $\text{H}_2\text{O}$  give green compds. In ice-cold aq. alk. soln. both the yellow and the green ketone give the same dibenzoate, yellow, m.  $191^\circ$ . Under the ultramicroscope solns. of the green form are strongly colloidal, those of the yellow form almost optically void, but with excess of alkali both yield the same colloidal red solns. The time reaction when the HCl salt is dissolved in alkali can be followed much better than with I; it depends on the temp. (is more rapid in hot than in cold soln.) and on the concn. of the alkali; its velocity did not seem, at least at first, to increase with the concn. of the alkali. Divanillacyclohexanone, from vanillin, cyclohexanone and HCl in abs. alc. at  $0^\circ$ , seps. as a dark blue-violet HCl salt which becomes dark green when washed with  $\text{Et}_2\text{O}$  and, if rapidly dried over  $\text{P}_2\text{O}_5$  and  $\text{H}_2\text{SO}_4$ , contains less than 1 mol. HCl. The blue-violet salt with  $\text{H}_2\text{O}$  gives a light green cryst. prepn. which does not turn yellow even on boiling but is converted into the yellow form by dissolving in dil. KOH and pptg. with AcOH (NaOH gives a brown-yellow salt). The yellow ppts., soon after their formation, are turned green by dil. HCl, but after 5–10 mins. (i. e., after they have become cryst.) the same HCl has practically no action on them; from alc. they sep. in yellow needles, m.  $179^\circ$ . The time reaction in the alk. solns. of the blue-violet or green HCl salts is much slower than that of the salts of II. Errata in earlier papers.—C. A. 19, 1414: for blue-black A-HCl deriv. of *p*-hydroxybenzal-*p*-hydroxyacetophenone, read red A-HCl deriv. C. A. 19, 1415: strike out the cor. m. ps.  $166^\circ$ ,  $178^\circ$  for dianisalcyclohexanone; the temps.  $162^\circ$ ,  $173^\circ$  are the cor. values. C. A. 16, 188 (p. 2264 of original): a compd., m.  $176^\circ$ , has been repeatedly obtained from suberone and anisaldehyde, and in addn. higher melting condensation products of doubtful compn.; Wallach's dianisalsuberone, m.  $128.9^\circ$ , is believed to be monotropic cryst.-liquid, the m. p. sometimes being lower ( $124^\circ$ ), the suberone obtained by different methods from suberic acid seemed to consist of a mixt. of several ketones. C. A. 5, 506: in Table VI, l. 14, read  $\text{CMe}_3\text{CO}_2\text{K}$  for  $\text{CMe}_3\text{CO}_2\text{Na}$ . The m. ps. of Na palmitate and stearate given in l. 9–11 from below were detd. "in tubes" and are therefore different from the values detd. "microscopically" (l. 12–14 from below); the latter are the less reliable, as the Rinne app. then used proved not to be trustworthy.

5-Phenyl-1-pentadienal and 7-phenyl-1-heptatrienal. II. D. VORLÄNDER AND ERICH DAEHN. *Ber.* 62B, 541–5 (1929).—Shortly after the appearance of the first paper by V., Fischer and Kunze (C. A. 19, 2940), V.'s attention was called to the fact that the 5-phenyl-1-pentadienal (I) and 7-phenyl-1-heptatrienal (II) had already been described by Engelberg (*Diss. Berlin, 1914*), working under Erlenmeyer with the co-operation of Schimmel & Co. E. and E. therefore had much larger amts. of the crude aldehyde at their disposal than did V., F. and K., but when the high-boiling fractions are to be sepd. from the mixt., it is perhaps better to work with smaller amts. to avoid decompn. during the long vacuum distns. In spite of some differences in the m. p. data, there can be no doubt of the identity of V., F. and K.'s I with E. and E.'s product. The investigation has been continued with a com. product (tailings in the fractionation of synthetic  $\text{PhCH:CHCHO}$  supplied by Schimmel and Co.). This contains 10–5%  $\text{PhCH:CHCO}_2\text{H}$  which was removed with  $\text{Na}_2\text{CO}_3$ . The residual oil (0.5 kg. after drying with  $\text{Na}_2\text{SO}_4$ ) yielded under 10–5 mm.  $18\%$  b.  $145^\circ$  (chiefly  $\text{PhCH:CHCHO}$ ),  $7\%$  b.  $145\text{--}57^\circ$ ,  $9\%$  b.  $157\text{--}65^\circ$ ,  $17\%$  b.  $165\text{--}79^\circ$  (also chiefly I),  $9\%$  b.  $180\text{--}95^\circ$ ,  $14\%$  b. above  $195^\circ$  and  $26\%$  residue. Fractions 3 and 4, refractionated twice more under 10–25 mm., gave a fraction, b.  $160\text{--}8^\circ$ , of I sufficiently pure for further synthetical expts. The condensation of  $\text{PhCH:CHCHO}$  in the lab. is effected much more rapidly by E. and E.'s than by V., F. and K.'s method, but MeOH was used instead of EtOH; 100 g.  $\text{PhCH:CHCHO}$ , 200 g. MeOH, 100 cc.  $\text{H}_2\text{O}$  and 100 g. 50% aq. AcH slowly treated at  $0\text{--}5^\circ$  with 100 g. 5% NaOH and allowed to stand 5 hrs. in ice gave 15–20 g. I, b.  $160\text{--}80^\circ$ , together with 30–40 g. unchanged  $\text{PhCH:CHCHO}$ . I and amines, from mol. quantities in alc. or without a solvent heated 2–4 hrs. at  $50\text{--}70^\circ$  or allowed to stand 1–3 days at room temp.: Aniline,  $\text{C}_7\text{H}_7\text{N}$ ,

refractive yellow leaflets, m. 112° (m. ps. cor.), non-cryst.-liquid (c.-l.), gives a color with concd.  $\text{H}_2\text{SO}_4$ ; *p*-toluidine, yellow, m. 105°, non-c.-l., gives an orange color with  $\text{H}_2\text{SO}_4$ ; *p*-anisidine, dark yellow, m. 147° (V., F. and K., 143°), monotropic c.-l. schlieren, 2 cryst.-solid phases; *p*-phenetidine, golden yellow, m. 137° (V., F. and K., 133-4°), monotropic c.-l. schlieren; *p*-aminoazobenzene, red-yellow, enantiotropic c.-l. schlieren, 1st m. p. 168°, 2nd m. p. 163° (V., F. and K., 172°-168°), gives a blue-violet color with  $\text{H}_2\text{SO}_4$ ;  $\beta$ -naphthylamine, yellow, m. 140°, non-c.-l., gives a red color with  $\text{H}_2\text{SO}_4$ ; *p*-aminoacetophenone, yellow, apparently 2 monotropic c.-l. phases, schlieren along 1 axis, gives a crimson color with concd.  $\text{H}_2\text{SO}_4$ ; phenylhydrazine, yellow, m. 178° (V., F. and K., 170-2°; E. and E., 177°), non-c.-l., gives a dirty green color with  $\text{H}_2\text{SO}_4$ ; hydrazine, yellow leaflets from alc., m. 210°, or golden yellow leaflets from  $\text{C}_6\text{H}_6$ , m. 217° (V., F. and K. from alc., 207-9°; E. and E. from AcOH, 207°), dimorphous cryst.-solid, mixed m. p. of the 2 forms 206-10°, non-c.-l., gives a red-violet color with  $\text{H}_2\text{SO}_4$ . I with ketones: acetone, m. 189°, monotropic c.-l. after the 1st fusion; acetophenone, yellow, m. 79°, non-c.-l., amorphous liquid when supercooled after fusing, gives a red-violet color with  $\text{H}_2\text{SO}_4$ ; cyclopentanone, red, m. 203-4°, changes on heating into 2 cryst.-solid forms, non-c.-l., gives a blue color with  $\text{H}_2\text{SO}_4$ ; cyclohexanone, m. 202°, monotropic c.-l. The earlier work had shown that II can be obtained from the higher boiling aldehyde fractions in the form of well characterized derivs. but a repetition of this work on the larger amts. of com. aldehyde rendered the prospects of obtaining II less promising. The 180-95° fraction, which should have contained II, gave on repeated distn. an oil, b<sub>14</sub> 185-95°, from which were obtained the following condensation products: with  $\text{PhNHNH}_2$ , a very small amt. of a cryst. powder or needles, non-c.-l., m. 189°, gives an orange color with  $\text{H}_2\text{SO}_4$ ; with *p*-phenetidine, yellow, enantiotropic c.-l. schlieren, solidifies cryst.-solid without supercooling, m. 188° and 164°, gives an orange color with  $\text{H}_2\text{SO}_4$  (V., F. and K. give 200° and 171° as the 2 m. ps.); with *p*-anisidine, yellow, m. 183°, strongly monotropic c.-l. schlieren, gives a yellow color with  $\text{H}_2\text{SO}_4$  (V., F. and K. describe their product as enantiotropic c.-l., m. 205-7° and 165°); with *p*-PhN:NC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>, golden yellow, enantiotropic c.-l. schlieren, m. 250-2° and 208-10°, gives a crimson color with  $\text{H}_2\text{SO}_4$  (V., F. and K. give the m. ps. as 300° and 251°). As the m. ps. given by V., F. and K. are in general higher, they possibly did not have derivs. of II but of a higher ene-homolog. The statement of E. and E. that II cannot be sepd. by vacuum distn. from the higher boiling residues in the prepn. of I (condensation in alc.) has been confirmed; this applies, however, only to the condensation products of I and AcH as they are obtained in the presence of large amts. of alc. in the short time of 5 hrs., not when the procedure of V., F. and K. (condensation in the presence of much H<sub>2</sub>O and little alc. for several days) is followed. The II (?) obtained by E. and E.'s method was enantiotropic c.-l., m. 110° and 104° (in another expt., 103° and 101°; E. and E., 98°), and reduced NH<sub>2</sub>-AgNO<sub>3</sub>; the c.-l. properties of some of its condensation products with amines were strikingly weak and differed in m. p. from those obtained by V., F. and K.; the substance seems to be a mixt. of higher aldehydes.

C A R

**7-Phenylheptatrienic acid.** D. VORLÄNDER AND ERICH DAEHN. *Ber.* 62B, 545-9 (1929); cf. preceding abstr.—The study of 7-phenylheptatrienic acid (I) was of interest from the point of view of the behavior of the 3 double bonds in addn. reactions and of the question whether cryst.-liquid (c.-l.) properties are strengthened by lengthening the chain even without *p*-substitution. Unlike the aldehyde, I can be obtained pure and was shown to be enantiotropic c.-l. There is thus now available the series B $\cdot$ OH, PhCH:CHCO<sub>2</sub>H, PhCH:CHCH:CHCO<sub>2</sub>H and I in which the c.-l. properties increase with the lengthening of the chain and introduction of each further CH:CH group, although it does not establish whether the C:C groups act only spatially by lengthening the chain, or also energetically, or, which is most probable, cumulatively through several very different functions. The yield of phenylpentadienalmalonic acid was increased from 40 to 60% by using alc. NH<sub>3</sub> instead of AcOH in the condensation; it seps. from alc. in orange needles, m. about 191° (m. ps. cor.) with evolution of CO<sub>2</sub> (Erlenmeyer and Engelberg, 190°; V., Fischer and Kunze, 210-2°). With 2 parts Ac<sub>2</sub>O at 120-30° it gives about 30% I, almost colorless or yellowish white, gives a yellow-brown color with  $\text{H}_2\text{SO}_4$ , m. 199° and 189-90° (E. and E., 187°). K, Na and NH<sub>4</sub> salts, microcryst. ppts. I and its Na salt in H<sub>2</sub>O suspension are strikingly stable toward light, even ultra-violet, only a small part decomp. In CHCl<sub>3</sub> I adds 3 mols. Br<sub>2</sub> without appreciable evolution of HBr. Me ester, prepd. with MeOH and H<sub>2</sub>SO<sub>4</sub>, very faintly yellowish, m. 114°, non-c.-l., gives a brown color with  $\text{H}_2\text{SO}_4$ ; Et ester, almost colorless, m. 91°, non-c.-l. (a mixt. of the Me and Et esters is likewise non-c.-l.).

can be supercooled and then solidifies rhythmically with marked contraction; this cryst.-solid phase changes on standing into 2 cryst.-solid phases. *Chloride*, prepd. with  $\text{SOCl}_2$ , brownish mass. *Anilide*, dull yellow, m.  $213^\circ$ , forms 2 cryst.-solid phases, non-c.-l., gives a red-brown color with  $\text{H}_2\text{SO}_4$ . *p-Toluide*, pale yellow, m.  $209^\circ$ , faint monotropic c.-l. *schlieren*, gives a red-brown color with  $\text{H}_2\text{SO}_4$ . *p-Aniside*, yellow-green, dimorphous enantiotropic c.-l., m.  $203-4^\circ$  (presumably transition solid  $\rightarrow$  c.-l.), gives a red-brown color with  $\text{H}_2\text{SO}_4$ . *p-Phenide*, yellow-greenish, m.  $210-1^\circ$ , enantiotropic c.-l., then amorphous-liquid; like the aniside, on cooling there appear a 1st and a 2nd cryst.-liquid phase. With Na-Hg and  $\text{CO}_2$  in  $\text{H}_2\text{O}$  on the  $\text{H}_2\text{O}$  bath, I gives a *di-* or *tetrahydro deriv.*, waxy leaflets, m.  $64^\circ$ , gives a brown color with  $\text{H}_2\text{SO}_4$ , reduces  $\text{KMnO}_4$ , is non-c.-l., becomes yellowish and sticky after 2-3 days in the air and light. The C content lies between the values calcd. for  $\text{C}_{13}\text{H}_{11}\text{O}_2$  and  $\text{C}_{13}\text{H}_{12}\text{O}_2$  and the H content is too low for the latter formula but titration with Br in  $\text{CHCl}_3$  points to a tetrahydro acid with only one C:C bond. There are no definite relations between the light and color phenomena under a quartz ultra-violet lamp and the degree of unsatn. of the compds. *p-MeOC}\_6\text{H}\_4\text{CHBrCHBrCHBrCHBrCO}\_2\text{H} shines with an unusually bright pink color, anisic acid glows at least as strongly as *p-MeOC}\_6\text{H}\_4\text{CH:CHCO}\_2\text{H} or the Me ester of I, but BzOH more weakly than  $\text{PhCH:CHCO}_2\text{H}$ . The phenomenon changes with shifting of the double bond from *p-MeOC}\_6\text{H}\_4\text{CH}\_2\text{CH:CHCH}\_2\text{CO}\_2\text{H} (faintly luminous) to the  $\alpha,\beta$ -unsatd. isomer (strongly luminous) or on rearrangement of  $\text{MeOC}_6\text{H}_4\text{CH:CHCH:CHCO}_2\text{H}$  (strongly luminous) into the *allo* acid (weakly luminous). Complete hydrogenation usually, but apparently not always, decreases the luminescence. All the arylideneamines hitherto tested appear black in the light of the quartz Hg lamp, as does Et *p*-azoxycinnamate, whereas phenylhydrazones glow brightly and the anilides, anisides, etc., of the acids are more or less bright. C. A. R.***

**Synthesis of isomeric ephedrine and their homologs.** WILHELM N. NAGAI AND SEIZO KANAO. *Ann.* **470**, 157-82(1929); cf. *C. A.* **23**, 1472.—BzH (10.6 g.) and 7.5 g.  $\text{EtNO}_2$ , shaken 5 days with 8 cc. 25%  $\text{K}_2\text{CO}_3$ , give 80% of 1-phenyl-1-hydroxy-2-nitropropane, b<sub>4</sub>  $123-4^\circ$ ; reduction with Zn and 25% AcOH in EtOH gives the 2-hydroxy-amino deriv., m.  $78-9^\circ$ ; shaking with 35% HCHO in  $\text{H}_2\text{O}$  the methylenemirone deriv., m.  $100^\circ$ ; reduction with Zn and AcOH in the presence of  $\text{CuSO}_4$  gives *dl*-ephedrine (1-phenyl-1-hydroxy-2-methylaminopropane) (I), m.  $75^\circ$ ; *HCl* salt, m.  $187-8^\circ$ ; chloroplatinate, yellow, m.  $199^\circ$ ; chloroaurate, yellow, m.  $112-3^\circ$ ; *p*-nitrobenzoyl deriv., pale yellow, m.  $162^\circ$ ; dimethylammonium iodide, m.  $228-9^\circ$ . Resolution of I with *d*-tartaric acid gives *l*-I, identical with the natural product; the *d*-I, m.  $40-40.5^\circ$ ,  $[\alpha]_D^{20}$   $+4.42^\circ$ , *p*-nitrobenzoyl deriv., pale yellow, m.  $187-8^\circ$ ,  $[\alpha]_D^{20}$   $+51.12^\circ$  ( $\text{CHCl}_3$ ). The 2nd product of the above reduction, which crystals first from  $\text{H}_2\text{O}$ , is *dl*-isoeephedrine (II), m.  $118^\circ$ , *HCl* salt, m.  $164^\circ$ ; oxalate, m.  $218^\circ$  (decompn.); chloroaurate, yellow, m.  $117^\circ$ , and pale yellow, m.  $194^\circ$ ;  $\text{CuSO}_4$  gives the compd.  $2\text{C}_{10}\text{H}_{12}\text{NO} \cdot \text{CuO} \cdot 2\text{H}_2\text{O}$ , violet, m.  $129^\circ$  (decompn.); *N*-*p*-nitrobenzoyl deriv., m.  $165-6^\circ$ ; dimethylammonium iodide, m.  $183^\circ$ . Resolution of II with *d*-tartaric acid gives *l*-II, m.  $118-8.5^\circ$ ,  $[\alpha]_D^{20}$   $-51.93^\circ$  (EtOH); *HCl* salt, m.  $182-2.5^\circ$ ,  $[\alpha]_D^{20}$   $-61.88^\circ$  ( $\text{H}_2\text{O}$ ); *N*-*p*-nitrobenzoyl deriv., m.  $177^\circ$ ,  $[\alpha]_D^{20}$   $-140.47^\circ$  ( $\text{CHCl}_3$ ). The mother liquor gives *d*-II, identical with the natural product. Reduction of  $\text{PhCH(OH)CH(NO}_2\text{)Me}$  with Fe and  $\text{H}_2\text{SO}_4$  in EtOH at  $45^\circ$  gives a mixt. of *dl*-norephedrine (III) and *dl*-norisoeephedrine (IV), sepd. by crystn. of the *HCl* salts from abs. EtOH. III, m.  $104-5^\circ$ ; *HCl* salt, m.  $194^\circ$ ; sulfate, m.  $285-6^\circ$ ; oxalate, m.  $245^\circ$  (decompn.); dioxalate, m.  $182-3^\circ$  (decompd.); chloroplatinate, pale yellow, m.  $221.5^\circ$  (decompn.); chloroaurate, yellow; compd.  $2\text{C}_{10}\text{H}_{12}\text{NO} \cdot \text{CuO} \cdot 2\text{H}_2\text{O}$ , purple, m.  $169^\circ$  (decompn.); *N*-Ac deriv., m.  $135^\circ$  (*N* *HCl* gives III; concd. *HCl* gives IV); *N*-*p*-nitrobenzoyl deriv., m.  $189^\circ$ . Resolution of III with *d*-tartaric acid gives *d*-III, m.  $52^\circ$ ,  $[\alpha]_D^{27}$   $+14.76^\circ$  (EtOH); *d*-bitartrate, crystg. with 1 EtOH, m.  $160^\circ$ ,  $[\alpha]_D^{27}$   $+34.69^\circ$ ; *HCl* salt, m.  $171-2^\circ$ ,  $[\alpha]_D^{27}$   $+33.40^\circ$ ; sulfate, crystg. with 2  $\text{H}_2\text{O}$ , m.  $285-6^\circ$  (decompn.),  $[\alpha]_D^{27}$   $+31.51^\circ$ ; oxalate, m.  $245^\circ$  (decompn.); chloroplatinate, pale yellow, m.  $221.5^\circ$  (decompn.); chloroaurate, yellow, m.  $188^\circ$ ; *N*-*p*-nitrobenzoyl deriv., pale yellow, m.  $175-6^\circ$ ,  $[\alpha]_D^{20}$   $+49.95^\circ$  ( $\text{CHCl}_3$ ). The mother liquor contains the *l*-III, m.  $50^\circ$ , of which the same derivs. were prepd.; the *p*-nitrobenzoyl deriv., pale yellow, m.  $175-6^\circ$ , on heating with concd. *HCl*, gives the corresponding deriv. of IV, m.  $71^\circ$ , is much more sol. in  $\text{Et}_2\text{O}$  than III; *HCl* salt, m.  $169^\circ$ ; sulfate, m.  $290.1^\circ$  (decompn.); oxalate, m.  $235^\circ$  (decompn.); dioxalate, m.  $171^\circ$  (decompn.); chloroplatinate, yellow, m.  $199.5^\circ$  (decompn.); chloroaurate, yellow, m.  $132-3^\circ$ , compd.,  $2\text{C}_{10}\text{H}_{12}\text{NO} \cdot \text{CuO} \cdot 2\text{H}_2\text{O}$ , purple, m.  $154^\circ$  (decompn.); *N*-Ac deriv., m.  $85-6^\circ$ ; *N*-*p*-

*nitrobenzoyl deriv.*, pale yellow, m. 170°. Resolution with *d*-tartaric acid gives *l*-IV, m. 77.5–8°,  $[\alpha]_D^{20}$  –32.64° (EtOH); *d*-bitartrate, m. 202°,  $[\alpha]_D^{20}$  –13.39°; *HCl salt*, m. 180–1°,  $[\alpha]_D^{20}$  –42.68°; *sulfate*, m. 290–1° (decompn.);  $[\alpha]_D^{20}$  –39.99°; *N*-*p*-*nitrobenzoyl deriv.*, pale yellow, m. 199°,  $[\alpha]_D^{20}$  –105.13° (CHCl<sub>3</sub>); *oxalate*, m. 235° (decompn.); *chloroplatinate*, pale yellow, m. 199°; *chloroaurate*, yellow, m. 137–8°. The mother liquor contains the *d*-IV, identical with the natural product. *dl*-*N*-Benzoylnorisoephedrine, m. 143°, with concd. H<sub>2</sub>SO<sub>4</sub> gives  $\alpha,\mu$ -diphenyl- $\beta$ -methyloxazoline, PhCH<sub>2</sub>CHMe.N:CPh.O (75% yield) (*picrate*, m. 140–1°, which, heated with dil.

HCl, gives *dl*-norisoephedrine benzoate, m. 220° (*picrate*, yellow, m. 186° (decompn.); *sulfate*, m. 182° (decompn.)). *dl*-*N*-Benzoylnorisoephedrine, m. 128°. A mixt. of PhCH(OH)CH(NO<sub>2</sub>)Me and HCHO, reduced with Zn and AcOH, gives a mixt. of *dl*-methylephedrine (V) and *dl*-methylisoephedrine (VI), sepd. by crystn. of the HCl salts from Me<sub>2</sub>CO. V, m. 63.5–4.5°; *HCl salt*, m. 207–8°; *oxalate*, m. 170–1° (decompn.); *picrate*, light yellow, m. 124–5°; *chloroaurate*, yellow, m. 137°. Resolution with *d*-tartaric acid gives the *l*-V, identical with the natural product; the mother liquor gives the *d*-V. VI,  $b_{16}$  135.5°,  $b_{23}$  144.5° (cor.),  $d_D^{20}$  0.9917,  $n_D^{20}$  1.5148; *picrate*, light yellow, m. 148–8.5°. Resolution with *d*-tartaric acid gives the *d*-VI,  $b_{21}$  145–5.5°, m. 28–8.5°,  $d_D^{24}$  0.98566,  $n_D^{24}$  1.5109,  $[\alpha]_D^{20}$  48.00° (MeOH), identical with the natural product the mother liquor gives the *l*-VI.

The reaction of sunlight on the cinnamic acids and on the salts of *trans*-cinnamic acid. The trimorphism of *cis*-cinnamic acid. A. W. K. DE JONG. *Chem. Weekblad* 26, 270–5(1929).—de J. gives a compilation of the reactions of *cis*- and *trans*-cinnamic acid under influence of sunlight and discusses the modifications of the *cis*-acids. A large no. of references is given.

F. DE LEEUW

Reactions of nitroso derivatives on unsaturated compounds. VII. New isomers of *o*-nitrophenylpropionic and isotogenic es.ers. L. ALESSANDRI. *Gazz. chim. ital.* 58, 738–42(1928); cf. *C. A.* 23, 1635.—In the previous expts. on the transformation of 1,2-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>C:CCO<sub>2</sub>Et (I) to OC.C<sub>6</sub>H<sub>4</sub>.N(:O):CCO<sub>2</sub>Et (II) by the catalytic action

of aryl NO compds., a small quantity (2–17%) of a compd. (III), m. 121°, of the same % compn. as I was formed. A similar phenomenon has been described only once before (cf. Pfeiffer, *C. A.* 10, 1334), and so the nature of the compd. was investigated. With PhNO as catalyst and with a suitable solvent and other conditions favorable, 50–70% of III was obtained, with only 7% of II. Analysis and a mol. wt. detn. of III showed a compn. of C<sub>11</sub>H<sub>9</sub>O<sub>4</sub>N, i. e., identical with I, so that it is an isomer of I or II. Heating for a brief time above its m. p. transforms it to a yellow compd. (IV), m. 150–1°, which is very stable. This transformation occurs rapidly at 125° and very slowly at its m. p., and it is exothermic and irreversible. The compn. of IV shows it to be an isomer of III. Similarly the trace of compd. (V), m. 140°, obtained in the transformation of 1,2-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>C:CCO<sub>2</sub>Me (VI) to OC.C<sub>6</sub>H<sub>4</sub>.N(:O):CCO<sub>2</sub>Me (VII)

with PhNO as catalyst, was increased to 27% with 21% of VII by using *p*-ONC<sub>6</sub>H<sub>4</sub>OH under suitable conditions. V exists in 2 cryst. forms according to the conditions of sepn., the 1st form m. 139° and the 2nd form m. 141°. Analysis of the 1st form showed it to be of the same compn. as VI. Heated above its m. p., V is transformed into a yellow compd. (VIII), which exists in 2 cryst. forms, the 1st form m. 149–50° and the 2nd form m. 161–2°, the compn. of which is the same as V. These compds. therefore are isomers. The chem. constitution of these isomers of III and of V has not yet been established. Ruggli has obtained isomers of isotogenic derivs., to which the isomers of A. may bear a close relation.

C. C. DAVIS

Synthesis of an isomer of thyroxine and of related compounds. CHARLES R. HARRINGTON AND WM. MCCARTNEY. *J. Chem. Soc.* 1929, 892–7.—(4-MeOC<sub>6</sub>H<sub>4</sub>)<sub>2</sub>CHCl and Et K phthalimidomalonate, heated in C<sub>6</sub>H<sub>6</sub>Me<sub>2</sub> 4 hrs. at 145°, give Et di-[4-methoxyphenyl]methylphthalimidomalonate, m. 106° (75% yield); heated with 50% KOH for 1 hr. there results 75% of  $\alpha$ -*o*-carboxybenzamido- $\beta,\beta$ -di[4-methoxyphenyl]propionic anhydride, m. 209–10°; boiling this with HI and Ac<sub>2</sub>O gives  $\alpha$ -amino- $\beta,\beta$ -di[4-hydroxyphenyl]propionic acid (I), m. 241° (decompn.). The ice-cold soln. of I in NH<sub>4</sub>OH with I in KI (2.54 N) gives 60% of the 3,5-di-I deriv., m. 218° (decompn.). Heating I at 290–315° and 2 mm. gives 55% of  $\beta,\beta$ -di[4-hydroxyphenyl]ethylamine (II), m. 207–8°; *HCl salt*, m. 275°; *tri-Bz deriv.*, m. 200°; 3,5-di-I deriv., m. 232–3°. Et di-phenylmethylphthalimidomalonate, m. 117° (57% yield); hydrolysis with KOH gives  $\alpha$ -*o*-carboxybenzamido- $\beta,\beta$ -diphenylpropionic anhydride, m. 214–5°; HI and Ac<sub>2</sub>O

give 77% of  $\alpha$ -amino- $\beta,\beta$ -diphenylpropionic acid, m. 236° (decompn.). 3',5'-Dibromo-3,5-diiodothyronine, m. 244.5° (decompn.) (45% yield). Neither the di-I derivs of I or II showed any trace of the type of physiol. activity characteristic of thyroxine.

C. J. WEST

**Synthesis in the hydroaromatic series. II. Cantharidin.** OTTO DIELS AND KURT ALDER (WITH ERICH NAUJOJKS). *Ber.* 62B, 554-62 (1929); cf. *C. A.* 22, 1144.—The opinion expressed in the first paper that the new method of synthesis of hydroaromatic compds. there described would prove of wide applicability has been fully verified; the method has been successfully used in the most varied fields and in the present paper are reported observations made in connection with cantharidin (I). If I has the structure II (Gadamer), it would seem that it could be synthesized, by the new method, by addn. of pyrocinchonic anhydride (III) to furan and hydrogenation of the resulting product (IV). Preliminary work has made the prospects of accomplishing this synthesis very bright, for it has been possible to add III to cyclopentadiene to form the compd. (V), and maleic anhydride to furan to give the compd. (VI) which can readily be hydrogenated to "norcantharidin" (VII). VI on heating decomps. into its components and it might therefore be concluded that it is a "mol. compd." but such a view does not agree with the stability of VI and its easy hydrogenation to VII, the structure of which has been proved. Compds. of this type, contg. a bridge (which may consist of C or N or CH<sub>2</sub> or the like), seem to have a very great tendency to regenerate the system with conjugated double bonds, and decomps. of this kind have been noted so often in compds. with "endo"-unions and of undoubted structure that Staudinger's criticism (*C. A.* 23, 1622) of D. and A.'s formulation of Albrecht's cyclopentadiene-quinone is without valid foundation. v. Bruchhausen and Bersch (against whose invasion of this field D. and A. protest vigorously) have recently announced (*C. A.* 23, 1647) the prepn. of VI and VII but give no proof of their structure, which D. and A. have established as follows: VII with HCl or HBr gives the corresponding 3,6-dichloro(or bromo)hexahydrophthalic acid (VIII) (or IX), which are reduced to Baeyer's *trans*-C<sub>6</sub>H<sub>10</sub>(CO<sub>2</sub>H)<sub>2</sub>; furthermore, IX, when boiled with H<sub>2</sub>O or, better, with alkali, loses HBr and CO<sub>2</sub> and gives  $\Delta^{1,2}$ -cyclohexadiene which adds maleic anhydride to form 3,6-endo-ethylenetetrahydrophthalic anhydride (X).  $\alpha,\alpha'$ -Dimethylfuran adds maleic anhydride as readily as does furan, and the resulting product (XI) is readily hydrogenated to "isocantharidin" (XII) which, unlike VII, does not give a dihalogen deriv. with halogen acids but changes into 3,6-dimethyl- $\Delta^{2,6}$  or  $\Delta^{2,5}$ -dihydrophthalic acid; cautious oxidation of the latter gives 3,6,1,2-C<sub>6</sub>H<sub>2</sub>Me<sub>2</sub>(CO<sub>2</sub>H)<sub>2</sub>. These results show that the new method of synthesis is not limited in its application to acyclic and isocyclic "dienes" and that there is apparently no material difference in the passage to

heterocyclic systems like furan. VI, obtained quant. from maleic anhydride in Et<sub>2</sub>O suspension and 1 mol. furan, m. 125° (decompn. into its components), immediately reduces dil. alk. KMnO<sub>4</sub> but does not decolorize Br in cold CHCl<sub>3</sub>. V, from 3 g. III, 8 g. of the diene and 2 cc. C<sub>6</sub>H<sub>6</sub> heated 4 hrs. at 100° in a sealed tube, m. 155°. *Mono-Et* 3,6-endoxohexahydrophthalate, from VI hydrogenated 5 mins. in alc. with colloidal Pd, m. 107-8°, has a sharp bitter taste; in the calcd. amt. of Na<sub>2</sub>CO<sub>3</sub> it is hydrogenated with colloidal Pd in about 10 mins. to the anhydride (VII), m. 116-7°, stable toward KMnO<sub>4</sub> in Na<sub>2</sub>CO<sub>3</sub>, which, heated with H<sub>2</sub>O some hrs. at 100°, yields the acid, crystals with 1 H<sub>2</sub>O, m. 112-3° (foaming), has a strong acid taste; *mono-Me ester*, from VII refluxed 2 hrs. in MeOH, m. 146° (foaming). VIII, from VII heated 12 hrs. at 100° in a sealed tube with concd. HCl, m. 111°, has a weak acid taste. IX,  $\alpha$ -form (5 g. from 4 g. VII heated 12 hrs. at 100° with 40 cc. AcOH-HBr), m. 218-9° (foaming);  $\beta$ -form, from 3 g. VII heated 12 hrs. at 100° with aq. HBr (satd. at 0°), m. 177° (decompn.). 3,6-Endoxo-3,6-dimethyl- $\Delta^4$ -tetrahydrophthalic anhydride (XI), m. 78°, immediately reduces KMnO<sub>4</sub> in Na<sub>2</sub>CO<sub>3</sub>, is more stable than its lower homologs when heated above its m. p. Hexahydro compd. (XII), m. 121.5°, does not decolorize KMnO<sub>4</sub> in Na<sub>2</sub>CO<sub>3</sub> even on long standing, has no taste or odor but leaves a burning sensation

in the mouth and produces blisters on the tongue. *3,6-Dimethyl- $\Delta^3$ - $\delta^2$ -dihydrophthalic anhydride*, m. 159°, is strongly unsatd. towards  $\text{KMnO}_4$ . C. A. R.

Syntheses in the hydroaromatic series. III. Syntheses of terpenes, camphors, hydroaromatic and heterocyclic systems. OTTO DIELS AND KURT ALDER with WOLFGANG LÜBBERT, ERICH NAUJOKA, FRANZ QUERBERITZ, KARL RÖHL and HARRO SEIGBERG. *Ann.* 470, 62-103(1929); cf. *C. A.* 22, 1144 and preceding abstr.—The semicarbazone of *endo*-methylene-2,5-hexahydrobenzaldehyde(I), previously reported as m. 142°, on recrystn., m. 160.5°. I on standing in the ice box changes into a trimer, m. 178-9°. I, heated with  $\text{Ac}_2\text{O}$  and  $\text{AcONa}$  for 2 hrs., gives *enol-norcamphenilinaldehyde acetate*(II),  $b_{15}$  109-11°, decompd. by  $\text{O}_3$  in moist  $\text{C}_6\text{H}_6$  to norcamphor, m. 91-2° (semicarbazone, m. 196-7°). Catalytic reduction of I in  $\text{AcOH}$  with  $\text{PtCl}_4$  and H gives the *acetate*,  $b_{15}$  103-4° (also form II with Pd and H), of *endo*-methylene-2,5-hexahydrobenzyl alc.(III),  $b_{10}$  101-2°; phenylurethan, m. 118-9°; *iodide*,  $b_{14}$  107-9°; with  $\text{Me}_3\text{N}$  the latter yields *endo*-methylene-2,5-hexahydrobenzyltrimethylammonium iodide, m. 266-7°; treating with excess  $\text{Ag}_2\text{O}$  and dry distn. give *endo*-methylene-2,5-hexahydrobenzylidimethylamine, b. 182°; *picrate*, m. 172°. III yields a *xanthogenate*,  $b_{15}$  182°, which, distd. at normal pressure, decomp. at 200-20°, giving *norcamphene*,  $b_{15}$  123°,  $d_4^{25}$  0.8789; *nitroschloride*, m. 125°. I and  $\text{PhMgBr}$  give *phenyl-endo-methylene-2,5-cyclohexylcarbinol*,  $b_{20}$  162-5°; dehydration with  $\text{K}_2\text{SO}_4$  at 190° gives *phenyl-endo-methylene-2,5-cyclohexylidenemethane*,  $b_{15}$  145-7°. Careful heating of maleic anhydride and myrcene gives the *anhydride*(IV),  $b_{12}$  202-3°, m. 34-5°, of *4-isohexenyl-cis- $\Delta^4$ -tetrahydrophthalic acid*(V), m. 122-3°. Heating this acid with 35%  $\text{HBr}$  at 100° for 12 hrs. gives *1,1-dimethyloctahydronaphthalene-6,7-dicarboxylic acid*, m. 206-7°, slowly oxidized by alk.  $\text{KMnO}_4$  but not by  $\text{O}_3$ ;  $\text{AcCl}$  gives the *anhydride*, m. 215-7°. Catalytic reduction of IV gives the *anhydride*,  $b_{11}$  207°, m. 42°, of *4-isohexyl-cis- $\Delta^4$ -tetrahydrophthalic acid*. Heating the *cis*-acid with 30%  $\text{HBr}$  12 hrs. at 100° gives *4-isohexyl-trans- $\Delta^4$ -tetrahydrophthalic acid*, m. 169-70°. The  $\text{O}_3$  decompn. of V gives  *$\Delta^4$ -tetrahydrobenzene-1,2-dicarboxylic-4-propionic acid*, oily, analyzed as the *Ph salt*  $\text{MeCH:CHCHO}$  and  $\text{CH}_2\text{:CHCH:CH}_2$ , heated 4-5 hrs. at 150°, give *6-methyl- $\Delta^3$ -tetrahydrobenzaldehyde*(VI),  $b_{22}$  75°,  $b_{38}$  83° (semicarbazone, m. 168°). Similarly, isoprene gives the *3,6-di-Me deriv.*,  $b_{25}$  92-3° (semicarbazone, m. 179-80°); 1,3-dimethylbutadiene gives the *2,4,6-tri-Me deriv.*,  $b_{12}$  81-2° (semicarbazone, m. 183°); 2,3-dimethylbutadiene gives *3,4,6-tri-Me deriv.*,  $b_{12}$  89° (semicarbazone, m. 181°); 1,1,3-trimethylbutadiene gives the *compd.*  $\text{C}_{11}\text{H}_{16}\text{O}$ ,  $b_{18}$  93-5°.  $\text{CH}_2\text{:CHCHO}$  and isoprene, heated at 100°, give *3(4?)*-methyl- $\Delta^3$ -tetrahydrobenzaldehyde,  $b_{10}$  63-4° (semicarbazone, m. 146°), *3,4-di-Me deriv.*,  $b_{10}$  79° (semicarbazone, m. 172°); *2,4(3,5?)*-dimethyl- $\Delta^3$ ( $\Delta^4$ )-tetrahydrobenzaldehyde,  $b_{10}$  71-3° (semicarbazone, m. 174°).  $\text{MeCH:CHCHO}$  and myrcene, heated several hrs. at 150°, give *6-methyl-3-isohexenyl- $\Delta^3$ -tetrahydrobenzaldehyde*,  $b_{12}$  143-4°;  $\text{CH}_2\text{:CHCHO}$  and myrcene give the *compd.*  $\text{C}_{13}\text{H}_{20}\text{O}$ ,  $b_{17}$  134-6°, while  $\alpha$ -phellandrene gives the *compd.*  $\text{C}_{13}\text{H}_{20}\text{O}$ ,  $b_{12}$  128-30°, and with  $\text{MeCH:CHCHO}$  gives the *compd.*  $\text{C}_{14}\text{H}_{22}\text{O}$ ,  $b_{18}$  143-4°.  $\text{PhCH:CHCHO}$  and 1,3-dimethylbutadiene give the *compd.*  $\text{C}_{15}\text{H}_{18}\text{O}$ ,  $b_{16}$  156-8°. Reduction of VI (Pd and H) gives *hexahydro- $\alpha$ -toluylaldehyde*,  $b_{11}$  61-2° (semicarbazone, m. 155°). Air oxidation gives *trans-hexahydro- $\alpha$ -toluylaldehyde*(VII), m. 52°. Butadiene and  $\text{MeCH:CHCO}_2\text{H}$  give the *acid*,  $\text{C}_{11}\text{H}_{16}\text{O}_2$ , b. 144-5°, m. 68°, reduced to VII. 1,1,3-Trimethylbutadiene gives the *acid*  $\text{C}_{11}\text{H}_{16}\text{O}_2$ ,  $b_{14}$  166-8°, m. 88.5-9°; 1,3-dimethylbutadiene gives the *acid*  $\text{C}_{10}\text{H}_{16}\text{O}_2$ ,  $b_{11}$  131°, m. 98°. Sorbic acid and maleic anhydride give the *compd.*  $\text{C}_{10}\text{H}_{12}\text{O}_6$ , m. 198° (decompn.), while the Et ester gives a *compd.*, m. 117-8°. Heating  $\text{MeCH:CHCHO}$  and cyclopentadiene 4 hrs. at 100° gives a mixt. of *cis*- and *trans*-2,5-endo-methylene-6-methyl- $\Delta^3$ -tetrahydrobenzaldehyde(VIII). At 100° principally the *cis*- and at 150° practically only the *trans*-VIII is formed; crystn. from  $\text{MeCN}$  gives 2 semicarbazones, m. 158° and 181°, resp.; decompn. of the latter gives an VIII,  $b_{46}$  80°. Catalytic reduction of the semicarbazones gives 2 *compds.*, m. 166.5° and 174°, resp. The latter gives *trans*-2,5-endo-methylene-6-methylhexahydrobenzaldehyde,  $b_{12}$  90°; the *cis*-deriv.,  $b_{12}$  85°. Air oxidation gives *trans*- and *cis*-2,5-endo-methylenehexahydro- $\alpha$ -toluylaldehydes, m. 66° and  $b_{12}$  136-7°, resp. *3(4?)*-Methyl- $\Delta^3$ -tetrahydrobenzaldehyde and  $\text{Me}_2\text{CO}$ , shaken with  $\text{Ba(OH)}_2$  3-4 days, give the *compd.*  $\text{C}_{11}\text{H}_{16}\text{O}$ ,  $b_{18}$  121-2°. *2,4,6*-Trimethyl- $\Delta^4$ -tetrahydrobenzaldehyde and  $\text{Me}_2\text{CO}$  with  $\text{EtONa}$  give a *pseudotirone*,  $\text{C}_{11}\text{H}_{20}\text{O}$ , pale yellow,  $b_{20}$  138-9°; *p*-bromophenylhydrazine, m. 175°; *thiosemicarbazone*, m. 191-2°. The *2,4,6*-tetramethyl deriv. and  $\text{Me}_2\text{CO}$  give *methylirone*, whose *p*-bromophenylhydrazine, m. 155-6°. 1,3-Dimethylbutadiene and maleic anhydride give *3,5-dimethyl- $\Delta^4$ -tetrahydrophthalic anhydride*, m. 56-7°. Reduction of 1,3-dimethylbutadiene gives 2-methyl-2-pentene. The hydrocarbon  $\text{C}_8\text{H}_{16}$  obtained by Harries on dry distn. of the phosphate of 2-methyl-2,4-diaminopentane is shown to be 1,3-

dimethylbutadiene, as is that obtained by Saytzev from  $\text{CH}_3\text{:CHCH}_2\text{Br}$  and  $\text{Me}_2\text{CO}$  and that from  $\text{MeCH:CHAc}$  and  $\text{MeMgI}$ . Other hydrocarbons may be characterized by condensation with maleic anhydride; isoprene gives a compd. m. 63–4°; 1-methylbutadiene, m. 62°; 2,3-dimethylbutadiene, m. 78–9°; 1,4-dimethylbutadiene, m. 95–6°; trimethylbutadiene, m. 49°. *N*-Methylpyrrole gives the compd.,  $\text{C}_5\text{H}_9\text{O}_2\text{N}$ , m. 98–9°. C. J. WEST

**Synthesis of camphor.** The concentration of isobornyl acetate and its influence on the synthesis of camphor. MARIANO T. LACRUE. *Bull. inst. pin* 1929, 15–30.—To diminish the oily residue from the sapon. of the acetates of borneol and isoborneol in the synthesis of camphor, and to facilitate the purification of the borneol, it is recommended that, before sapon., the acetate be obtained about 98% pure by distns. under reduced pressure. The optimum cuts are worked out on the basis of exptl. data, and tables give the relations between the concn. of the acetate and the d. and n of the oil as a basis for controlling the cuts. The industrial significance of the procedure is discussed. MERRILL W. SEYMOUR

**Constitution of Manasse's  $\alpha$ - and  $\beta$ -hydroxycamphor (o-exo- and o-endo-hydroxycamphor).** II. J. BREDT. *J. prakt. Chem.* 121, 153–72(1929); cf. C. A. 20, 2157.—The mixt. of o-exo- and -endo-camphors (I and II) may be sepd. by forming the Me ether of II, which is volatile with steam (2 l.  $\text{H}_2\text{O}$  are necessary to remove 10 g.). The semicarbazone of II varies in m. p. depending upon the rate of heating; quick heating, 215–6°; slow heating, 210–1°. Active I gives a semicarbazone, m. 183–4°; the *dl*-deriv., m. 182–3°. Active bis-o-endo-hydroxycamphor Me ether, m. 149–50°, heated with abs. MeOH and dry HCl for 2–3 hrs, gives the monomeric Me ether of II,  $b_d$  81°,  $b_{12}$  105–6°, m. 37–8°,  $d_4^{25}$  0.9996,  $n_D^{25}$  1.4636 (semicarbazone, m. 124°). I and MeOH with dry HCl give the monomeric Me ether,  $b_{15}$  105–7°,  $d_4^{11}$  1.0202,  $n_D^{11}$  1.47426 (semicarbazone, m. 204°). Active II, m. 211–2°, and MeMgI give nearly quant. allomethylbornyleneglycol, m. 163–4°; the crude product from the inactive II, m. 97–100°, but could not be recrystd. The product from active I, m. 209–10°. Active I gives an acetate, m. 61–2°; benzoate,  $b_{0.33}$  168°; benzoate of II, m. 84–5°. The benzenesulfonate of active II, m. 110°; of I, m. 79–80°. The following formulas are proposed for I and II:

C. J. WEST

**Oxidation of  $d$ - $\Delta^4$ -carene with Beckmann's chromic acid mixture.** CHARLES S. GIBSON AND JOHN L. SIMONSEN. *J. Chem. Soc.* 1929, 909–10.—Oxidation of  $d$ - $\Delta^4$ -carene with Beckmann's  $\text{CrO}_3$  mixt. gives *l*-trans-caronic acid, identical with that obtained from  $d$ - $\Delta^3$ -carene; in addn. a small amt. of a neutral oil, yielding a semicarbazone, m. 205–7°, was obtained. C. J. WEST

**Fenchene series. I. Ozonization and constitution of the fenchenes.** GUST. KOMPPA AND R. H. ROSCHIER. *Ann.* 470, 129–56(1929).— $\alpha$ -Fenchene(I), b. 155–60°,  $d_4^{17.5}$  0.8670,  $n_D^{17.5}$  1.46729, and  $\text{O}_3$  in petroleum ether yield an ozonide which, decompd. in AcOH, yields *d*- $\alpha$ -fenchocamphorone, 1- $\alpha$ -fenchenylic acid (7,7-dimethyl-(1,2,2)-bicycloheptane-2-carboxylic acid), m. 71.5–2°, stable toward  $\text{KMnO}_4$  and  $\text{NaBrO}$  and does not react with CO reagents; anilide, m. 149.5–50°; various metallic salts are described. The corresponding aldehyde is also formed but could not be isolated in a pure state; oxidation gives the above acid. The ozonide of *dl*- $\beta$ -fenchene (II) (b. 151–3°,  $d_4^{17}$  0.8598,  $n_D^{17}$  1.46620), formed and decompd. in AcOH, gives *dl*- $\beta$ -fenchocamphorone, b. 185–95°; semicarbazone, m. 193–5°; this also results by the oxidation of the fenchene with  $\text{KMnO}_4$ . Oxidation of the ketone gives *dl*-apofenchocamphoric acid, m. 144–5°.  $\gamma$ -Fenchene (III), b. 145–7°,  $d_4^{17}$  0.8547,  $n_D^{17}$  1.46072 (which contains some  $\beta$ -fenchene), gives an ozonide, from which there is obtained the

*ketoaldehyde*,  $\text{Me}_2\text{C} \cdot \text{CH}(\text{CHO}) \cdot \text{CH}_2 \cdot \text{CHAc} \cdot \text{CH}_3$ ,  $b_{10}$  118–20°  $d_4^{20}$  1.0215,  $n_D^{20}$  1.4700,

$n_a$  1.4677,  $n_p$  1.4815; *disemicarbazone*, m. 219° (decompn.); a 2nd product is the corresponding *keto-acid*,  $\text{C}_{10}\text{H}_{16}\text{O}_3$ ,  $d_4^{20}$  1.0924,  $n_D^{20}$  1.4774; *semicarbazone*, m. 220 1°; *Ag salt*; *Cu salt*, light green.  $\text{NaBrO}$  oxidizes the *keto-acid* to a *dicarboxylic acid*,  $\text{Me}_2\text{C} \cdot \text{CH}(\text{CO}_2\text{H}) \cdot \text{CH}_2 \cdot \text{CH}(\text{CO}_2\text{H}) \cdot \text{CH}_3$ , m. 147–8°; 100 cc.  $\text{H}_2\text{O}$  at 25° dissolves

1.472 g. acid.  $\delta$ - or isofenchene(IV), b. 141–3°,  $d_4^{17}$  0.8476,  $n_D^{17}$  1.45424, through the ozonide, yields a *ketone*,  $\text{C}_9\text{H}_{14}\text{O}$ , whose *semicarbazone*, m. 209°; this is oxidized to a *dicarboxylic acid*,  $\text{C}_9\text{H}_{14}\text{O}_4$ , m. 117–8°. The acid is *dl-cis-fenchocamphoric acid*, m. 173–4°. In the ozonization of the last 2 products, there remains unattacked a part termed *cyclofenchene*(V),  $b_{782}$  142–3°,  $d_4^{16.5}$  0.8624,  $n_D^{16.5}$  1.45364, identical with  $\beta$  pinolene of Aschan (C. A. 6, 1144); through the acetate there results isofencheny! alc. *Cyclofenchene-HBr*,  $b_{12}$  92–3°, m. 4°,  $d_4^{20}$  1.2389,  $n_D^{20}$  1.50570. The formulas ascribed to these 5 fenchenes are:

C. J. WEST

**Biphenyls and their derivatives. III. Stereoisomerism of derivatives of monophenylnaphthalenes and binaphthyls.** LUIGI MASCARELLI. Reale Univ. Torino *Gazz. chim. ital.* 58, 791–800(1928); cf. C. A. 22, 68; 23, 2962. —A survey of the previous expts. on optical isomerism, in which a comparison was made of  $\text{Ph}_2$  derivs. which could and which could not be split into optical antipodes, leads to certain general conclusions. No derivs. (with the proper substituents) with the 2,6,2',6'-positions substituted possess free rotation. For the mol. to become asym., it is necessary that the 2,6-positions of 1 nucleus contain differing substituents, while the 3rd substituent in the other nucleus can be but need not be the same as 1 of the substituents in the disubstituted nucleus. If all 4 of the 2,6,2',6'-positions are occupied by identical groups, there will be oscillation instead of free rotation, and only when at least 2 of the 4 substituents are different and are distributed in the 2 nuclei will the mol. be asym. In certain special cases, substituents in the 3,5,3',5'-positions contribute to the mol. asymmetry. On the other hand, substituents in the 4,4'-positions can have no influence. Free rotation exists when: (1) no H atom in the 2,2',6,6'-positions is substituted, (2) a single H atom in these positions is substituted, and (3) 2 H atoms in these positions and in the same  $\text{C}_6\text{H}_4$  nucleus are substituted. The rotation is impeded, *i. e.*, a nucleus oscillates, so that it describes an almost complete circle around the other nucleus, when only 2 H atoms belonging to the 2 nuclei (2,2'- or 6,6'-positions) are substituted. There is semicircular oscillation, *i. e.*, the oscillatory motion of 1 nucleus with respect to the other nucleus is limited almost to a semicircle, when at least 3 H atoms in the 2,2',6,6'-positions are substituted. Very numerous are the substances which show similar phenomena of stereoisomerism without contg. asym. atoms, including all those which can be considered as derivs. of  $\text{Ph}_2$ , *e. g.*, certain phenylnaphthalenes, binaphthyls, bianthracyls, bianthraquinonyls, biphenanthryls, bipyrnyls, bipyrindyls, biquinolyls, biindyls, bicarbazolyls and biacridyls. In the present paper the conditions governing mol. asymmetry in derivs. of the 2 monophenylnaphthalenes and the 3 binaphthyls are discussed. With the aid of known facts which govern optical isomerism in the  $\text{Ph}_2$  series, it is easy to det. the conditions under which the various derivs. show mol. asymmetry. The latter is manifest after more or less complex substitutions according to the position of the bond uniting the 2 nuclei. Several more compds. are studied, their structures being discussed in detail. Omitting the details of this theoretical

analysis of the various compds., the following conclusions are reached.  $\alpha$ -Phenyl-naphthalenes follow the same general principles as  $\text{Ph}_2$  derivs. Only the 2,2',6'- and the 3',5'-positions play a part in bringing about mol. asymmetry, since  $\alpha\text{-C}_{10}\text{H}_7\text{Ph}$  has (because of its inherent structure) its 5,6-positions occupied.  $\beta\text{-C}_{10}\text{H}_7\text{Ph}$  derivs. are similar to those of the  $\text{Ph}_2$  series, since here, too, asymmetry begins with the tri-substituted derivs. and the 2,6,2',6'-positions and the 3,3',5'-positions have a determinant influence on the asymmetry. The only difference between  $\beta\text{-C}_{10}\text{H}_7\text{Ph}$  derivs. and  $\text{Ph}_2$  derivs. is the fact that the 5-position does not play a part, since it is already occupied in the former derivs. Among the 1,1'-dinaphthyl derivs. ( $\alpha, \alpha$ -,  $\beta, \beta$ - and to have mol. asymmetry. Two substituents (identical or different) in the 2,2'-positions render the mol. asym. Substitution in any other position than 2 or 2' has no influence on the asymmetry, though in certain cases the 8,8'-positions form an exception to this. In 2,2'-binaphthyl derivs., substitution in the 2,6,2',6'-positions alone can produce mol. asymmetry. This asymmetry is produced as soon as any 3 of the positions mentioned are occupied by like or unlike substituents. In 1,2'-binaphthyl derivs., substitution in the 2,6,6'-positions alone can produce mol. asymmetry, the latter manifesting itself as soon as any 2 of the positions mentioned are occupied by like or by unlike substituents. Asymmetry persists if there are 3 substituents (like or unlike) in the 2,6,6'-positions. These generalities are fully confirmed by cases already to be found in the literature. IV. The great number of optical antipodes, containing no

biphenyl     $\alpha$ -phenyl-     $\beta$ -phenyl-    1,1'-binaphthyl    2,2'-binaphthyl    1,2'-binaphthyl  
naphthalene    naphthalene

asymmetric atoms, which can be derived from them. *Ibid* 865-9.- A survey of the results published so far leads to the following summary, the data giving the type of compd., whether or not there is free rotation, the no. of substituents sufficient for impeded rotation, the no. of substituents sufficient for semicircular oscillation, the no. of substituents sufficient for mol. asymmetry, the other positions influencing asymmetry, and the no. of substituents with which asymmetry begins, resp.: Biphenyls, yes; 2 (equal or not) distributed between 2,2' or 6,6'; 3 (equal or not) between 2,6,2',6'; 3 (of which at least 2 are different and are distributed on 1 nucleus among 2,6,2',6'); 3,5 and 3',5'; 3.  $\alpha$ -Phenyl-naphthalene, yes; 1 in 2' or 6'; 2 (equal or not) between 2,2', 6'; 2 between 2,2',6' (if equally distributed on 2 nuclei with 2 always occupied, if different anywhere); 3',5' (special position 8); 2.  $\beta$ -Phenyl-naphthalene, yes; 2 (equal or not) between 2,2'; 3 (equal or not) among 2,6,2',6'; 3 among 2,6,2',6' (of which 1 is different and distributed so that 2',6' are different or so that only 1 of the 2',6' is occupied); 3,3',5'; 3. 1,1'-Binaphthyls, no; 0; 1 between 2,2'; 1 between 2,2'; 0 (special positions 8,8'), 1. 2,2'-Binaphthyls, yes; 2 (equal or not) between 2,2' or 6,6'; 3 (equal or not) among 2,6,2',6'; 3 (equal or not) among 2,6,2',6'; 0; 3. 1,2'-Binaphthyls, yes; 1 between 2,6; 2 (equal or not) between 2,2',6'; 2 (equal or not) between 2,2',6'; 0 (special position 8'); 2. The more complex the mols. become on account of the addn. of substituents (which often leads to an increase in the no. of elements of asymmetry), the smaller the no. of conditions necessary for producing mol. asymmetry. In all 6 types of compd. the bond uniting the 2 nuclei of the mol. functions as an axis of rotation, and mol. asymmetry exists only when the 2 nuclei cannot rotate freely but are restricted

to semicircular oscillation. This restriction exists when at least 3 of the 4 positions nearest to those of the bond (which may be termed *o* to the bond) are occupied by the proper substituents. In the diagrams, the imaginary vertical line cutting the 2 nuclei and dividing each compd. into a right and left part makes it possible to ascertain directly whether or not the mol. is asym. Mol. asymmetry exists when the parts on the right (A and B) are mirror images of the corresponding parts on the left (A' and B'). All polysubstituted derivs. of 1,1'-binaphthyl (besides that which contains a substituent in 1 of the 2,2'-positions) are asym., provided that at least 1 of the 2,2'-positions is occupied. Substitution in the 4,4'-positions can have no influence. All polysubstituted derivs. of 2,2'-binaphthyl which contain at least 3 substituents distributed among the 2,6,2',6'-positions are asym. All polysubstituted derivs. of 1,2'-binaphthyl which contain at least 2 substituents distributed among the 2,6,2',6'-positions are asym. Substitution in the 4 position can have no influence. The structure of the 3 binaphthyls is such that, as soon as the nuclei are restrained (by the presence of certain substituents in certain positions) to semicircular oscillation with respect to 1 another, the mol. structure acquires an asym. configuration which no new substituent can overcome. On the other hand the Ph<sub>3</sub> mol. is so constructed that even when the mol. becomes asym. by the proper substituents, it may become again sym. by further substitution. Because of the presence of a C<sub>6</sub>H<sub>5</sub> and a C<sub>10</sub>H<sub>7</sub> nucleus, C<sub>10</sub>H<sub>7</sub>:Ph derivs. show a behavior intermediate between that of Ph<sub>3</sub> and binaphthyl.

**Intermolecular condensation of styryl ketones. III. Further examples of the ready formation of bis(styryl ketones).** ISIDOR M. HEILBRON and FRANCIS IRVING, *J. Chem. Soc.* 1929, 931-6; cf. C. A. 23, 116.—*Bis(styryl Pr ketone)*, m. 194-5°, results from BzH and MeCOPr; concd. H<sub>2</sub>SO<sub>4</sub> gives a yellow soln.; Vorländer (*Ber.* 30, 2267 (1897)) considered this a complex triketone. MeCOBu and BzH give *bis(styryl Bu ketone)*, m. 175-6°. BzH and MeCOCH<sub>2</sub>CHMe<sub>2</sub> give *bis(styryl iso-Bu ketone)*, m. 202°; this also results from styryl iso-Bu ketone and 25% NaOH in EtOH at room temp. Cuminal and MeCOCH<sub>2</sub>CHMe<sub>2</sub> with alkali give *bis[4-isopropylstyryl iso-Bu ketone]*, m. 192-4°, unsuccessful attempts were made to obtain dimerides by the condensation of MeCO:CH<sub>2</sub>CHMe<sub>2</sub> with piperonal, veratraldehyde and *p*-ClC<sub>6</sub>H<sub>4</sub>CHO. BzH and MeCOC<sub>6</sub>H<sub>13</sub> give *bis(styryl hexyl ketone)*, m. 152°, while *p*-MeOC<sub>6</sub>H<sub>4</sub>CHO gives the 4-MeO deriv., m. 145-6°. 4-Methoxystyryl hexyl ketone, m. 55°. *Bis(styryl isohexyl ketone)*, m. 177°; the heptyl homolog, m. 144°; the octyl homolog, m. 131.5°; *styryl octyl ketone*, pale yellow, m. 38-9°. In general, the higher members of the series of the bis-compds are more easily produced; a substituted aldehyde gives rise to a dimeride less readily than BzH itself. Dimerides are only formed from branched-chain ketones when at least 1 CH<sub>2</sub> group seps. the branch radical from the CO group. The solvent appears to be 1 of the main factors detg. the formation of the mono- or bis-form during the condensation; in aq. EtOH (60-70%) the styryl ketone itself is formed but in abs EtOH the dimeride is produced even under the same conditions of alkali concn.

C. J. WEST

**New derivatives of triphenylmethane.** HEINRICH WEILAND and HELLMUT KLOSS *Ann.* 470, 201-23 (1929).—The Grignard reagent from 1.2 g. Mg and 5.5 g. EtBr and C<sub>6</sub>H<sub>5</sub>I is shaken with 9 g. Ph<sub>3</sub>CCl (deep violet color) and decompd. in the usual manner, there results 1-1.5 g. of hexaphenylbutane, m. 260°, stable towards Br, KMnO<sub>4</sub>, CrO<sub>3</sub> in AcOH, O<sub>2</sub>, and catalytic reduction; fuming HNO<sub>3</sub> gives the hexa-NO<sub>2</sub> deriv., yellow-green, m. above 300°. PhC:CH and Ph<sub>3</sub>CCl give tetraphenylpropine, PhC(CPh<sub>3</sub>)<sub>2</sub>, m. 139°; it is as unreactive towards oxidizing agents and Br as the hexa-Ph deriv., tetra-NO<sub>2</sub> deriv., light yellow, m. 182° (decompn.); catalytic reduction gives 1,1,1,3-tetraphenylpropane, m. 126°. *p*-Tritolylphenylpropine, m. 141° (80% yield); reduction gives 1,1,1-tri-*p*-tolyl-3-cyclohexylpropane, m. 126°. Ph<sub>3</sub>CHC:CCPh<sub>2</sub>, m. 114°, is obtained similarly in 40-50% yields. 1,1,3-Triphenylpropine, m. 79° (80% yield), catalytic reduction (Pd black) gives 1,1,3-triphenylpropane, m. 46°, also obtained by reducing the corresponding alc. with HI and P; reduction with Pt oxide gives 60% of 1-cyclohexyl-3,5-diphenylpropane(?), b<sub>1</sub> 160-70°. Oxidation of PhC:CCPh<sub>2</sub> with KMnO<sub>4</sub> gives (PhC(CPh<sub>2</sub>))<sub>2</sub>, m. 179°; this was also obtained from PhC(C(OH)Ph<sub>2</sub>) with TiCl<sub>4</sub>; in a boiling soln. of C<sub>6</sub>H<sub>5</sub>Me<sub>3</sub> or C<sub>10</sub>H<sub>7</sub> a deep orange-red color develops, indicating dissocn.; this disappears on cooling; solns. at temps. below 100° are colorless. (Ph<sub>3</sub>C(OH)C:); and PCl<sub>5</sub> in Et<sub>2</sub>O for 12 hrs. gives 1-diphenylmethylene-2-chloro-3-phenylindene, deep red, m. 158°; reduction with HI and P in boiling AcOH gives diphenylmethylenephenylindene, m. 205-6°, after 15 mins. or the tetrahydro deriv., m. 133°, after 1 hr.; after 0.5 hr. there results the intermediate dihydro deriv., m. 115°. Ph<sub>3</sub>CN<sub>3</sub> and Ph<sub>3</sub>CCOCl in abs. Et<sub>2</sub>O (N atm.), shaken for 6 hrs., and the product decompd. with ice H<sub>2</sub>O in the presence of Et<sub>2</sub>O, give *p*-triphenylacetyltriphenylmethane, m. 183-

4°; decompn. with alkali gives  $\text{Ph}_3\text{CH}$  and  $p\text{-Ph}_2\text{CHC}_6\text{H}_4\text{CO}_2\text{H}$ ; reduction gives the hydrocarbon,  $p\text{-Ph}_2\text{CHC}_6\text{H}_4\text{CH}_2\text{CPh}_3$ , m. 177°.  $\text{Ph}_3\text{CNa}$  and  $\text{Ph}_2\text{CHCOCl}$  give 30–40% of  $\text{Ph}_2\text{CCOCHPh}_3$ , m. 180°.

C. J. WEST

**Pyrogenic decomposition of aromatic compounds with hydrogen under pressure in the presence of a mixed catalyst.** II. V. IPAT'EV AND N. ORLOV. *Ber.* 62B, 593–7 (1929); cf. *C. A.* 22, 396; 23, 3567.—It was shown in the 1st paper that a whole series of aromatic compds. heated with H and a catalyst ( $\text{Al}_2\text{O}_3$ ) yield products of lower b. p. and richer in H and that certain com. products (solvent naphtha and coal-tar oil) can be converted, with good yields, into  $\text{C}_6\text{H}_6$  hydrocarbons. In such a pyrogenesis of a heavy,  $\text{C}_{10}\text{H}_8$ -free oil was obtained a considerable amt. of  $\text{C}_{10}\text{H}_8$  which, it was assumed, was produced from substituted naphthalenes in the oil. The object of the present work was to obtain exptl. confirmation of this assumption. It was also of interest to explain the appearance of a small amt. of benzene; the simplest assumption was that it was produced at the expense of the paraffins always present in coal tar. The formation of  $\text{NH}_3$  in the pyrogenesis and the fact that  $\text{PhNH}_2$  is readily decompd. into  $\text{C}_6\text{H}_6$  and  $\text{NH}_3$  naturally suggested a study of the behavior of org. bases under the same conditions. The earlier work established with sufficient clearness that the formation of lighter hydrocarbons from solvent naphtha is the result of dealkylation of  $\text{C}_6\text{H}_6$  homologs; it has now been found that another constituent of the naphtha, viz., indene, under a sufficiently high H pressure, is very easily converted into hydriodene and is then further decompd. into substituted benzenes, under a smaller pressure it is almost completely changed into a thick resin which does not distil without decompn. Tetralin heated under the pressure of its own vapor (without H) forms  $\text{C}_6\text{H}_6$  hydrocarbons (as with H) and at the same time undergoes dehydrogenation with formation of a considerable amt. of high-boiling condensation products. Unlike  $\text{CH}_2\text{-Ph}_2$ ,  $(\text{CH}_2\text{Ph})_2$  is decompd. with extraordinary ease, giving  $\text{PhMe}$ . In the presence of an  $\text{Fe}_2\text{O}_3\text{-Al}_2\text{O}_3$  catalyst the crude com. products are completely freed of S compds. All the expts. were carried out in an 800 cc. Ipat'ev high-pressure app. with 7–10% of a mixt. of equal parts  $\text{Fe}_2\text{O}_3$  and  $\text{Al}_2\text{O}_3$  as catalyst; initial H pressure, about 70 atm.; temp., 440–65°.  $\alpha\text{-C}_{10}\text{H}_7\text{Me}$  (50 g.) gave  $\text{CH}_4$  (7% of the gaseous products), 27 g.  $\text{C}_{10}\text{H}_8$ , and  $\text{C}_6\text{H}_6$  hydrocarbons, hydro- and methylhydronaphthalenes; 50 g.  $\beta\text{-C}_{10}\text{H}_7\text{Me}$  gave 11 g.  $\text{C}_{10}\text{H}_8$ , 8 g.  $\text{C}_6\text{H}_6$  hydrocarbons and 14 g. hydrogenated naphthalenes; from 87 g. of the products of pyrogenesis of 1,6- $\text{C}_{10}\text{H}_6\text{Me}_2$  were obtained 16 g.  $\text{C}_6\text{H}_6$  hydrocarbons, 28 g.  $\text{C}_{10}\text{H}_8$  and an oil yielding  $\beta\text{-C}_{10}\text{H}_7\text{Me}$  on dehydrogenation; 2,6- $\text{C}_{10}\text{H}_6\text{Me}_2$  behaved in the same way. From 35 g. paraffin after 12 hrs. was obtained 22 cc. benzene, b. 50–170°,  $d_4^{20}$  0.7211,  $n_D^{20}$  1.412, completely indifferent toward  $\text{H}_2\text{SO}_4$  and nitrating acid. Carbazole after 18 hrs. showed only a quite insignificant alteration while 35 g. quinoline after 10 hrs. gave  $\text{NH}_3$  and 7 g. hydrocarbon, b. 80–150°,  $d_4^{25}$  0.8763, vigorously attacked by  $\text{H}_2\text{SO}_4$  and nitrating acid. Unlike  $(\text{CH}_2\text{Ph})_2$  and  $\text{Ph}_2\text{O}$ , dibiphenylene oxide remained completely unchanged after 10 hrs.

C. A. R.

**Products of nitration of 2-naphthol-6-sulfonic acid.** N. N. VOROZHTZOV AND N. M. KASATKIN. *Bull. inst. polytech. Ivanovo-Vosniesensk* 11, 75–85 (1928).—V. and K. undertook the investigation of reactions of nitration of  $\beta$ -naphtholsulfonic acids, beginning with Schaeffer's salt (I), which, when treated with  $\text{HNO}_3$  in presence of monohydrate  $\text{H}_2\text{SO}_4$  to form mononitro derivs., produces 13% of the yellow mononitro compd. and 32% of the red dinitro compd., and when treated to form dinitro deriv. gives 78% of the red dinitro compd. only. The mononitro compd. proved to be structurally identical with the 1,2,6- $\text{C}_{10}\text{H}_6(\text{NO}_2)(\text{OH})\text{SO}_3\text{H}$  obtained by oxidation of the corresponding nitroso compd., while the formula of the dinitro deriv. is uncertain. The Ba salts of the nitrated I are insol. in  $\text{H}_2\text{O}$ , the Pb salts are poorly sol. in  $\text{H}_2\text{O}$ . The comparative study of solubilities shows that the 2 red dinitro compds. obtained by nitration to mononitro and to dinitro derivs. are identical.

CHAS. BLANC

**Methods of preparation and conversion of 1,5-nitronaphthylamine.** N. N. VOROZHTZOV AND A. A. KULEV. *Bull. inst. polytech. Ivanovo-Vosniesensk* 9, 87–93 (1928).—V. and K. give improved methods of prepn. of 1,5- $\text{C}_{10}\text{H}_6(\text{NO}_2)\text{NH}_2$  (I) from  $\text{C}_{10}\text{H}_6(\text{NO}_2)_2$  (II), and the conversion of I to 1,5- $\text{C}_{10}\text{H}_6(\text{NO}_2)\text{OH}$  (III) and 1,5- $\text{C}_{10}\text{H}_6(\text{NH}_2)\text{OH}$  (IV). II was isolated from the com. product when 100 g. of the latter was dissolved in 1000 g. of  $\text{H}_2\text{SO}_4$ , d. 1.83, at 100°, the soln. cooled to 20°, the pptd. 1,5-isomer filtered off at 20°, washed free from the acid; yield 20.5 g., m. 200°; when recrystd from  $\text{PhNO}_2$ , yield 14.5 g., m. 217°. By another method II was obtained when 100 g. of com. product was dissolved in 600 cc. of  $\text{PhNH}_2$  on the water bath, cooled to 0°, the pptd. II filtered off, washed with dild. HCl and then with  $\text{H}_2\text{O}$ , yield 29 g., m. 212°. II was then converted to I when 9 g. of  $\text{Na}_2\text{S}$  in 20 cc. of  $\text{H}_2\text{O}$  was added at 85° to a mixt. of 10 g.

of **II** with 14.5 g. of  $(\text{NH}_4)_2\text{SO}_4$  in 50 cc. of  $\text{H}_2\text{O}$ , the ppt. was collected on a filter, treated with  $\text{HCl}$ , the  $\text{HCl}$  ext. was made alk. with  $\text{NH}_3$ , and the pptd. **I** was collected and dried; yield 40%, m.  $117^\circ$ . An improvement on the method of Morgan and Jones (*J. Soc. Chem. Ind.* 341T(1923)) for prepn. of **I** was obtained when 300 g. of  $\text{C}_{10}\text{H}_7\text{NH}_2$  was dissolved in 3000 g. of  $\text{H}_2\text{SO}_4$  (d. 1.84) at  $10^\circ$ , to which was added a mixt. of 120 cc. of  $\text{HNO}_3$  (d. 1.437), and 210 cc. of  $\text{H}_2\text{SO}_4$  at  $1-3^\circ$ , the soln. was allowed to stand in the cold for 16 hrs., filtered and poured on ice, the ppt. of the sulfates of  $\text{C}_{10}\text{H}_6(\text{NO}_2)_2\text{NH}_2$  was filtered off and washed first with 1 l. of 3  $N$   $\text{H}_2\text{SO}_4$  and then with 1 l. of  $N$   $\text{H}_2\text{SO}_4$  to dissolve out the 1,8-isomer, then the remaining ppt. was twice recrystd. from hot  $\text{H}_2\text{O}$ , filtered, and the sulfate was converted to free base of **I** with dild.  $\text{NH}_3$ ; yield 102 g., m.  $105^\circ$ ; when dissolved in  $\text{HCl}$ , treated with  $\text{NH}_3$  and recrystd. from  $\text{C}_6\text{H}_6$ , m.  $117^\circ$ . **III** was obtained by diazotizing the sulfate of **I** and then substituting  $\text{OH}$  for the diazo group, the best yield (41.7%) having been secured by diazotizing in the course of 6 hrs., while in the substitution of  $\text{OH}$  for the diazo group the best yield was obtained with increased concn. of  $\text{H}_2\text{SO}_4$  in the bath. The addn. of  $\text{Cu}$  salts proved detrimental. It forms yellow needles, m.  $171^\circ$ . **IV** was obtained when 0.7 g. of **III** together with 1 g. of c. p.  $\text{Sn}$  and 50 cc. of  $\text{HCl}$  (d. 1.16), was heated on the water bath, cooled, sepd. from an excess of  $\text{Sn}$ , extd. with  $\text{CS}_2$ , treated with a soln. of  $\text{Na}_2\text{CO}_3$ , resulting in a white flocculent ppt. of **IV** (yield 88.12%); recrystd. from hot  $\text{H}_2\text{O}$  it forms long, pink needles, m.  $192^\circ$ .

CHAS. BLANC

**Stereochemistry of aromatic compounds. VIII. Optically active heterocyclic compounds and optically active azo dyes of the binaphthyl series.** RICHARD KUHN AND PAUL GOLDFINGER. *Ann.* 470, 183-200(1929); cf. *C. A.* 23, 1129. —(2- $\text{H}_2\text{NC}_{10}\text{H}_{6.5}$  (**I**) cannot be resolved by tartaric acid or by helicin but is resolved by *d*-camphorsulfonic acid. *d*-2,2'-Diamino-1,1'-binaphthyl (**II**), m.  $242.5-3^\circ$  (cor.);  $[\alpha]_D^{19} -46^\circ$  (2  $N$   $\text{HCl}$ ),  $-35^\circ$  ( $N$   $\text{HCl}$ ),  $183.8^\circ$  ( $\text{C}_6\text{H}_6$ ),  $[\alpha]_D^{20} -30^\circ$  ( $N$   $\text{HCl}$ ),  $149.5^\circ$  ( $\text{C}_6\text{H}_5\text{N}$ ),  $[\alpha]_D^{21} 21^\circ$  ( $\text{AcOH}$ ),  $144.5^\circ$  ( $\text{C}_6\text{H}_5\text{N}$ ); *d*-camphorsulfonate, m.  $243^\circ$  (cor.),  $[\alpha]_D^{19} 93.6^\circ$  ( $\text{C}_6\text{H}_5\text{N}$ ),  $[\text{M}]_D^{19} 483.0^\circ$ . The mother liquor gives the *l*-isomer (**III**), m.  $243^\circ$ ,  $[\alpha]_D^{18} 46.8^\circ$  (2  $N$   $\text{HCl}$ ). The active compd. is not racemized by heating with  $N$   $\text{HCl}$  for 6 hrs. at  $100^\circ$ . [2,6- $\text{Me}(\text{H}_3\text{N})\text{C}_6\text{H}_3$  and  $\text{Bz}_2$ , heated 15-20 min. at  $180-200^\circ$  give the *S*-yellow condensation product,  $\text{C}_{28}\text{H}_{22}\text{N}_2$ , m.  $213^\circ$ ; it ppts. unchanged from concd.  $\text{H}_2\text{SO}_4$ . **I** and  $\text{Bz}_2$  give a deep orange condensation product,  $\text{C}_{34}\text{H}_{26}\text{N}_2$ , m.  $275.5^\circ$  (cor.) and clears  $291.5^\circ$ , the **III** gives a compd., m.  $281^\circ$ ,  $[\alpha]_D^{19} 823.4^\circ$  ( $\text{C}_6\text{H}_5\text{N}$ ); another sample showed  $559.0^\circ$ . **II** gives a compd., m.  $295^\circ$ , with  $^{121} -1890^\circ$  ( $\text{C}_6\text{H}_5\text{N}$ ),  $-1800^\circ$  ( $\text{CHCl}_3$ ),  $-1410^\circ$  ( $\text{AcOH}$ ),  $-3270^\circ$  ( $\text{H}_2\text{SO}_4$ ); hydrolysis with 20%  $\text{HCl}$  gives the **II** again, m.  $206-16^\circ$ ,  $[\alpha]_D^{21} 59^\circ$  ( $\text{C}_6\text{H}_6$ ).  $(\text{O}_2\text{NC}_6\text{H}_4\text{CO})_2$  gives a deep bluish red melt, m.  $335^\circ$ ,  $[\alpha]_D^{21} -1611^\circ$  ( $\text{C}_6\text{H}_5\text{N}$ ). **II** gives a dibenzal compd., straw-colored, m.  $146^\circ$  (cor.),  $[\alpha]_D^{20} 129^\circ$  ( $\text{C}_6\text{H}_5\text{N}$ ),  $-130^\circ$  ( $\text{H}_2\text{SO}_4$ ). The *di*-*Ac* deriv. m.  $237^\circ$ ,  $[\alpha]_D^{21} 151.6^\circ$  ( $\text{AcOH}$ ); during catalytic reduction the optical activity is lost; this is also true of the condensation product with  $\text{Bz}_2$ . The diazo compd. from the **II** couples with *m*- $\text{C}_6\text{H}_4(\text{OH})_2$  to give a deep red azo dye,  $\text{C}_{32}\text{H}_{20}\text{O}_4\text{N}_4$ , decomps. above  $300^\circ$ ,  $[\alpha]_{5563}^{20} -1730^\circ$ ,  $[\alpha]_{5893}^{20} -3230^\circ$  ( $\text{C}_6\text{H}_5\text{N}$ ).  $[\alpha]^{20}$  for 6563, 5893, 5463 and 4861 are given for several of these compds.

C. J. WEST

***o*-Quinamines of the naphthalene series and their transformation into homologs of naphthyl-2-acetic acid.** K. FRIES AND A. KÜSTER. *Ann.* 470, 20-37(1929). cf. *C. A.* 22, 3146. —The crude *Br* deriv. from 1,2- $\text{C}_{10}\text{H}_6\text{Me}(\text{OH})$ , prepd. according to F. and Engel (*C. A.* 19, 59), gives with  $\text{PhNH}_2$  1-anilino-1-methyl-2-ketonaphthalene 1,2-dihydride (**I**), yellow, m.  $141^\circ$ ; concd.  $\text{H}_2\text{SO}_4$  gives an olive-green color; it is stable in alkalis and acids, reduced by  $\text{Zn}$  and  $\text{AcOH}$  to 1,2- $\text{C}_{10}\text{H}_6\text{Me}(\text{OH})$ . **I** and  $\text{Br}$  in  $\text{EtOH}$  give the 2',4'-dibromoanilino deriv., yellow, m.  $174^\circ$ ; reduction gives 2,4- $\text{Br}_2\text{C}_6\text{H}_3\text{NH}_2$  and 1,2- $\text{C}_{10}\text{H}_6\text{Me}(\text{OH})$ . Using *p*- $\text{BrC}_6\text{H}_4\text{NH}_2$  there results the 4'-bromoanilino deriv. of **I**, yellow, m.  $148^\circ$ . 1,6-Dibromo-1-methyl-2-ketonaphthalene 1,2-dihydride and  $\text{PhNH}_2$  give the 1-anilino deriv., golden yellow, m.  $149^\circ$ ; 1-[4'-bromoanilino] deriv., yellow, m.  $168^\circ$ ; 1-[2',4'-dibromoanilino] deriv., *S*-yellow, m.  $185^\circ$ . The above derivs. are not rearranged by acids. 1-Methyl-1-anilino-2-ket-4,6-dibromonaphthalene 1,2-dihydride (**II**), orange, m.  $200^\circ$ , is reduced by  $\text{Zn}$  to  $\text{PhNH}_2$  and 1,4,6,2- $\text{MeBr}_2\text{C}_{10}\text{H}_4\text{OH}$ ; in concd.  $\text{H}_2\text{SO}_4$  the green color soon changes to brown, giving 1-methyl-3,6-dibromo-2-naphthyl 4'-aminophenyl ether, yellow, m.  $137^\circ$ . **II** and 1 mol.  $\text{Br}$  in  $\text{EtOH}$  give the *N*-bromoanilino deriv., light yellow, m.  $187^\circ$ ; this also results from the 1,4,6- $\text{Br}_2$  deriv. and  $\text{PhNH}_2$  in  $\text{EtOH}$ ; the compd. is stable in boiling  $\text{EtOH}$  and  $\text{AcOH}$  but with  $\text{HCl}$ ,  $\text{HBr}$  or  $\text{H}_2\text{SO}_4$  rearranges to the 4-bromoanilino deriv., yellow, m.  $201^\circ$ .

also formed from the 1,4,6-Br<sub>3</sub> deriv. and *p*-BrC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>. The quinamine and Ac<sub>2</sub>O with a little H<sub>2</sub>SO<sub>4</sub> give 1-methyl-1-acetylanilino-2-ketonaphthalene 1,2-dihydride, m. 174° (90% yield); EtONa in EtOH, boiled 0.25 hr., gives 8-methyl-1-phenyl-2-oxo-[6,7-benzoindeole 2,8-dihydride] (III), m. 178° (80–5% yield); an intermediate product is 8-methyl-1-phenyl-2-ket-9-hydroxy-[6,7-benzoindeole 2,3,8,9-tetrahydride] (IV), m. 174°; soln. in concd. H<sub>2</sub>SO<sub>4</sub> and pptn. with H<sub>2</sub>O gives III; oxidation with CrO<sub>3</sub> in AcOH gives 50% of a compd. C<sub>19</sub>H<sub>15</sub>O<sub>5</sub>N. The Me ether of IV, m. 184°. Catalytic reduction of IV in AcOH gives the 2,3,4,5,8,9-hexahydride, m. 159°, stable toward dil. alkali; Ac. deriv., m. 152°. III and Br in CHCl<sub>3</sub> give 8-methyl-1-phenyl-2-ket-3,4,5,9-tetra-bromo-[6,7-benzoindeole 2,3,4,5,8,9-hexahydride], m. 200° (decompn.). Reduction of III with SnCl<sub>2</sub> and AcOH gives 8-methyl-1-phenyl-2-ket-[6,7-benzoindeole 2,3,5,8-tetrahydride], m. 189°, pptd. unchanged from concd. HCl or H<sub>2</sub>SO<sub>4</sub>; reduction of IV gives the same compd. Catalytic reduction of III gives the 2,3,4,5,8,9-hexahydride, m. 145°. Reduction of III with amalgamated Zn in AcOH gives 95% of 1-methyl-2-naphthylacetic acid, m. 166°; amide, m. 228°. Heating the Na salt with Cu and soda lime at 380–400° at 12 mm., there results from 16 g. of the acid 6.4 g. 1,2-C<sub>10</sub>H<sub>8</sub>Me<sub>2</sub>. I and (EtCO)<sub>2</sub>O with a little H<sub>2</sub>SO<sub>4</sub> give the 1-propionylanilino deriv., m. 142°; with EtONa this gives 3,8-dimethyl-1-phenyl-2-ket-[6,7-benzoindeole 2,8-dihydride], m. 165°; reduced according to Clemmensen to methyl-[1-methyl-2-naphthyl]acetic acid, m. 128°. 1-Acetylanilino deriv. of I, m. 226°; 8-methyl-1-phenyl-2-ket-9-hydroxy-6,7-[4'-bromo-2,1'-benzo]indole 2,3,8,9-tetrahydride, m. 201° (80% yield); 8-methyl-1-phenyl-2-ket-6,7-[4'-bromo-2',1'-benzo]indole 2,8-dihydride, m. 174° (75% yield); 6-bromo-1-methyl-2-naphthylacetic acid, m. 210° (90.5% yield). C. J. WüST

**Non-tannin substances in the extract of the root of badan (*Saxifraga crassifolia*).** I. BERGENIN, A. E. CHICHIBABIN, A. V. KIRSANOV, A. I. KORELEV and N. N. VOROZHTZOV, JR. *Ann.* **469**, 93–127 (1929); cf. Garreau and Machelart, *Compt. rend.* **91**, 942 (1880).—Bergenin (I), C<sub>14</sub>H<sub>16</sub>O<sub>6</sub>, crystg. with 1 H<sub>2</sub>O, lost at 100°, [α]<sub>D</sub> –37.25° (0.99% EtOH soln.) (mono- and di-Na and K salts), isolated from the Me<sub>2</sub>CO exts. of badan roots after removal of tannins, contains 6 HO groups and 1 MeO group but no CO<sub>2</sub>H or free CO groups. Excess of Ac<sub>2</sub>O and I give the penta-Ac deriv., m. 199–203°, which still contains 1 free HO group; with a smaller excess of Ac<sub>2</sub>O, a product, m. 192–3°, was obtained which was not examd. I and CH<sub>2</sub>N<sub>2</sub> in Et<sub>2</sub>O give a di-Me deriv., crystg. with 2 H<sub>2</sub>O, m. 89°, anhyd., m. 194–6°; oxidation with KMnO<sub>4</sub> gives a mixt. of 4,5,6-trimethoxysisocoumarin (II), m. 84°; 3,4,5-trimethoxysisocoumarin-2-carboxylic acid (III), m. 254° (decompn.) (Ag salt), which yields II by distn. in vacuo (Me ester, m. 155–6°); and 3,4,5-trimethoxyphthalic acid, b<sub>17</sub> 226°, m. 139–40°, with conversion into its anhydride but in a bath at 170° it m. 176–7° (decompn.). Heating 1.18 g. II with 50 cc. 0.1 N NaOH gives a compd., m. 122–8° (decompn.); after heating at 200° the compd. C<sub>12</sub>H<sub>14</sub>O<sub>6</sub>, m. 72–6° and crystals with 0.5 C<sub>6</sub>H<sub>6</sub>; using 20 cc. 0.5 N NaOH there results a compd. C<sub>24</sub>H<sub>26</sub>O<sub>11</sub>, m. 185–6°. Oxidation of II with alk. KMnO<sub>4</sub> converts it into 3,4,5-trimethoxyhomophthalic acid, m. 145–6°; distn. at 14 mm. gives the anhydride, m. 124–5°; this acid was synthesized from 4-hydroxy-3,5-dimethoxyphthalide-2-carboxylic acid by reduction with HI and red P and rapid methylation in a H atm. of the resulting trihydroxyhomophthalic acid with Me<sub>2</sub>SO. Fusion of I with KOH at 200° converts it into 3,5,4-(HO)<sub>2</sub>MeOC<sub>6</sub>H<sub>2</sub>CO<sub>2</sub>H. On the basis of these results the structural conclusions of Sadikov and Guthner (*C. A.* **22**, 1767) are criticized and structure IV is assigned to I; in agreement with this, I titrates as a lactone.

The following reactions are less readily explained. I couples normally in alk. soln. with 1 mol. of PhN<sub>2</sub>Cl to yield benzeneazobergenin (V), orange-red, decomp. 200°, which, however, can couple with a 2nd mol. of PhN<sub>2</sub>Cl to yield the compd. C<sub>14</sub>H<sub>14</sub>O<sub>8</sub> (NPh)<sub>2</sub>, brown; both dyes color wool in an acid bath brownish yellow to brown. V is reduced by SnCl<sub>2</sub> and HCl to (3)-aminobergenin, crystg. with 3 H<sub>2</sub>O, light yellow, m. (anhyd.) 244° (decompn.); with HNO<sub>2</sub> there results a diazo oxide, light yellow, crystg. with 2 H<sub>2</sub>O. Like the parent isocoumarin, II and III are converted by NH<sub>3</sub>

**New meso-derivatives of anthracene and dianthryl.** B. P. FEDOROV. *Bull. inst. polytech. Ivanovo-Vosnesensk* 9, 103-9(1928).—By direct sulfonation of anthracene (I) the  $\text{SO}_3\text{H}$  groups are introduced into the side rings. F. has discovered that by the action of  $\text{Na}_2\text{SO}_3$  on *ms*-nitroanthracene (II) the  $\text{SO}_3\text{Na}$  group is substituted for  $\text{NO}_2$  forming *Na ms*-anthracenesulfonate (III). The  $\text{SO}_3\text{Na}$  attached to the *ms*-C atom is highly reactive and easily replaced by H on boiling with dil. mineral acids, giving I, and by OH on heating with alkalis, giving anthranol, while on heating with  $\text{NH}_3$  under pressure it forms *ms*-anthramine. In the action of  $\text{Na}_2\text{SO}_3$  on II there is also formed a by-product, *Na dianthryl-ms-sulfonate* (IV), the  $\text{SO}_3\text{H}$  group of which is readily replaced by H, OH,  $\text{NH}_2$ , etc., forming *ms-hydroxydianthryl* (V) and *ms-aminodianthryl* (VI), all of which were hitherto unknown. *Exptl. part.*—Eighteen g. of II with 45 cc. of 19.3%  $\text{NaHSO}_3$ , 3.35 g. of 100% NaOH in 10 cc. of  $\text{H}_2\text{O}$  and 50 cc. of  $\text{H}_2\text{O}$  is simmered 4 hrs. in an air bath, the contents are poured into 100 cc. of iced  $\text{H}_2\text{O}$ , cooled to  $5^\circ$ , and after 3 hrs. filtered from the ppt. of unchanged II and IV. The latter is twice boiled with dil. alc., filtered boiling hot, evapd. to 300 cc., salted out hot, cooled, filtered and recrystd. from dil. alc.; yield of IV 1.7 g., which crystallizes with 1 mol. of  $\text{H}_2\text{O}$ , insol. in cold  $\text{H}_2\text{O}$ , sparingly sol. in hot  $\text{H}_2\text{O}$ , easily sol. in hot alc. IV can also be produced with poor yield from III by boiling with very dil. NaOH. IV on boiling with dil. mineral acids is quant. decompd. into  $\text{SO}_2$  and dianthryl. The decompn. to dianthryl and anthraquinone proves that S in IV is attached to the *ms*-C atom. When IV is fused with NaOH and the melt treated with HCl there is formed a small amt. of V, which was not further investigated. VI is obtained when 1.5 g. of IV is heated with 25 cc. of 20%  $\text{NH}_4\text{OH}$  in a sealed tube at  $190-200^\circ$  for 10 hrs. and filtered; yield 0.92 g., faintly yellow rods from  $\text{C}_6\text{H}_6$  or  $\text{PhCH}_3$ , m.  $305^\circ$  (decompn.). *ms*-Anthramine when diazotized acts abnormally, forming anthraquinone and diamino-dianthryl (*Ber.* 40, 518(1907)), while VI is normally diazotized in alc. and will slowly couple with  $\beta$ -naphthol to a cherry-red azo soln., which on standing deposits a brown dyestuff; with other hydroxynaphthalenes and their  $\text{SO}_3\text{H}$  acids VI gives yellow, red and brown azo dyes. The filtrate obtained after sepn. of II and IV, contr. III and  $\text{NaNO}_2$ , is cooled and treated with  $\text{SO}_2$ , the excess of  $\text{SO}_2$  is neutralized with  $\text{Na}_2\text{CO}_3$ , evapd. to dryness, taken up in warm alc., filtered, evapd. and dried over  $\text{H}_2\text{SO}_4$ ; yield of III 17 g., colorless prisms, easily sol. in  $\text{H}_2\text{O}$ , poorly sol. in alc. On boiling with dil. mineral acids III is decompd. into  $\text{SO}_2$  and I, probably with formation of anthranol as an intermediary product. This and the oxidation with  $\text{KMnO}_4$  to anthraquinone prove that S is attached to the *ms*-C atom. Anthranol, obtained when 1 g. of III is heated with 3 g. of NaOH at  $200-10^\circ$ , made acid with HCl, filtered, crystd. from alc., m.  $163-4^\circ$  (poor yield). *ms*-Anthramine is produced when 1 g. of III is heated in a sealed tube with 15 cc. of 20%  $\text{NH}_4\text{OH}$  at  $200^\circ$  for 4 hrs., the contents quickly filtered, dissolved in alc., satd. with HCl, the HCl salt is filtered and dried; yield 20-25%. The alc. soln. gives with diazobenzenesulfonic acid the Goldmann color reaction (*Ber.* 23, 2522(1890)). The free base forms yellow plates, m.  $115-6^\circ$ , and not  $145-50^\circ$  as is given in *Ann.* 330, 166(1904). CHAS. BLANC

**Differently colored states of anthrahydroquinonecarboxylic acids, and anthrahydroquinone- $\alpha$ -carboxylic lactones.** ROLAND SCHOLL, OSKAR BÖTTGER AND SIGFRIED HASS. *Ber.* 62B, 616-28(1929).—The incentive to this work was certain observations on the  $\text{Na}_2\text{S}_2\text{O}_4$  reduction products of anthraquinonecarboxylic acids which in their formation and color strikingly resembled the so-called aryloxanthronyls, dark blue free org. radicals, described some yrs. ago. When the red  $\text{Na}_2\text{S}_2\text{O}_4$  vat, prepd. in the cold, of  $1\text{-C}_6\text{H}_4(\text{CO})_2\text{C}_6\text{H}_3\text{CO}_2\text{H}$  (I) is treated with HCl the vat acid seps. as a red jelly which, however, soon becomes brown-violet, even under N. Similarly the red vat acid from  $2,6\text{-HO}_2\text{CC}_6\text{H}_3(\text{CO})_2\text{C}_6\text{H}_3\text{CO}_2\text{H}$  (II) becomes violet after a time while the red aq. alk. vat of the 1,5-acid (III) at once gives a violet ppt. with HCl. The almost colorless, neutral, aq. soln. of the Na salt of III gives with  $\text{Na}_2\text{S}_2\text{O}_4$  at room temp. an orange-red vat which, when shaken with air in the presence of an excess of  $\text{Na}_2\text{S}_2\text{O}_4$ , yields a violet ppt. If the almost colorless, free, amorphous III or II or the 1,3,5,7-tetracarboxylic acid (V) in aq. suspension is treated with an excess of  $\text{Na}_2\text{S}_2\text{O}_4$  there are formed yellow-red to yellow-brown solns. giving violet ppts. when shaken with air; in the absence of an excess of  $\text{Na}_2\text{S}_2\text{O}_4$  or in the presence of mineral acids the suspended acids can be converted directly into violet ppts. While these facts are strikingly reminiscent of the corresponding phenomena with the oxanthronyls, the violet ppts. are not free radicals. The vat acid from the red alk. vat of I was prepd. in the complete absence of air and under conditions under which anthrahydroquinone and its derivs. are not sepd. into oxidized and reduced parts. There were thus obtained in good yield brownish violet  $\text{KMnO}_4$ -like crystals, almost brick-red by transmitted light,

pptd. from their sol. salts by means of alkali. To this mixt., suspended in 100 parts water, is added 14.2 parts (by vol.) 0.1 *N* KOH, the mixt. taken up by 200-250 parts (by vol.) of pea-sized pumice particles and the whole dried at 400-500°. The other method consists of fractional crystn. of crude anthracene from furfural, the anthracene content being raised by 2 such treatments from 31 to 90%. A previous purification with *o*-C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub> will remove phenanthrene and neutral oils.

E. PICKERING

**Unsaponifiable matter from the oils of elasmobranch fish. V. Constitution of squalene as deduced from its degradation products.** ISIDOR M. HEILBRON, WM. M. OWENS AND IAN A. SIMPSON. *J. Chem. Soc.* 1929, 873-83; cf. *C. A.* 22, 2363.—This work was undertaken with the idea of proving that under all methods of attack squalene (I) yields decompn. products typical of those to be anticipated from a triterpene hydrocarbon. The results have enabled definite structural formulas to be ascribed to the isomeric hydrocarbons of which it is composed. Distn. of I at 300-350 mm. in a *N* atm. gives, excluding the hemiterpene fraction, consisting mainly of Me<sub>2</sub>C:CHMe, 70% of a golden yellow mobile liquid; distn. at 20 mm. gives 30% of a fraction b<sub>40</sub> 100°; further distn. gives a fraction b<sub>15</sub> 60-3°, d<sub>4</sub><sup>17.6</sup> 0.8225, n<sub>D</sub><sup>20</sup> 1.4619, which, however, on redistn. b<sub>740</sub> 162-77°; distn. over Na gives several fractions, of which 2, b<sub>740</sub> 167-70°, 174-6°, were studied; while the Br values agree with C<sub>10</sub>H<sub>18</sub>, the I nos. are high, these are considered to be const.-boiling mixts. rather than individual substances. The hot-wire method of decompn. (Chapman, *C. A.* 17, 2262) fails to confirm the existence of a single substance, such as heparene reported by C. Indications of the presence of an unsatd. open-chain terpene (myrcene?) have been furnished by an expt. in which the monoterpene fraction, b<sub>20</sub> 60-100°, was heated 24 hrs. with 99% HCO<sub>2</sub>H. The last fraction of the reaction product resembled a diterpene. The expts. of Majima and Kubota (*C. A.* 16, 3628) on the action of O<sub>3</sub> upon I have been confirmed; the supposed acids C<sub>8</sub>H<sub>10</sub>O<sub>6</sub> and C<sub>8</sub>H<sub>14</sub>O<sub>6</sub> are now shown to be levulinic aldehyde peroxide, C<sub>8</sub>H<sub>10</sub>O<sub>6</sub>, m. 195°, and probably methylheptenone peroxide, C<sub>8</sub>H<sub>14</sub>O<sub>6</sub>, m. 136°. C.'s results on the oxidation of I with KMnO<sub>4</sub> have been confirmed in general; however, addn. of solid KMnO<sub>4</sub> to I in Me<sub>2</sub>CO gives small amts. of dihydro-ψ-ionone (geranylacetone) and probably methylheptenone; even an excess of KMnO<sub>4</sub> and heating leaves about 40% of the I unchanged; this residual I yields a HCl salt from which the high-melting isomer is easily obtained, which is further evidence that I is a mixt. of 2 isomers and suggests that 1 isomer is more readily broken down than the other. Oxidation of I with CrO<sub>3</sub>Cl<sub>2</sub> in CS<sub>2</sub> gives small amts. of HCHO, AcH, (CH<sub>2</sub>CO<sub>2</sub>H)<sub>2</sub> and much resinous material. Bromination of I from several sources in Et<sub>2</sub>O at -25° gives a product, sepd. by crystn. from AcOEt into a high-melting fraction, m. 198°, C<sub>30</sub>H<sub>50</sub>O<sub>2</sub>, and a low-melting fraction, m. 178°, which decompn. in moist air and could not be recrystd.

**VI. Constitution of squalene as deduced from a study of the decahydrosqualenes.** I. M. HEILBRON AND ALBERT THOMPSON. *Ibid* 883 92.—Hydrogenation of squalene until 5 mols. of H had been absorbed gave a product (II), b<sub>3</sub> 227-30°; this was treated with O<sub>3</sub> for 36 hrs. (until Br was no longer absorbed) and the ozonide decompd. by boiling with H<sub>2</sub>O for 2 hrs. in an atm. of N; 450 g. II gave 502 g. ozonide from which 16 g. steam-volatile ketone, 287 g. of neutral, non-steam-volatile matter, including 35% of squalene, and 178 g. of mixed acids were obtained. The steam-volatile fraction is *Me isohexyl ketone*, b<sub>785</sub> 164-6°, whose semicarbazone m. 149-50°. The non-volatile neutral fraction was divided into 3 fractions, b<sub>12</sub> 124-45°, b<sub>3</sub> 155-75° and b<sub>2</sub> 200-10°; the 1st fraction contains hexahydro-ψ-ionone, b<sub>11</sub> 119-21°, whose semicarbazone m. 97-8°. The 2nd fraction contains 3,7,11-trimethyl-15-hexadecanone, C<sub>19</sub>H<sub>38</sub>O, whose semicarbazone m. 71.5-3.5°. The 3rd fraction contains 3,7,11,15-tetramethyl-19-eicosanone(?), b<sub>1</sub> 195-205°. Since it might be supposed that the 2nd fraction contained 2,6,10-trimethyl-14-pentadecanone (III), this ketone was synthesized from hexahydrofarnesol, b<sub>3</sub> 125-8°, n<sub>D</sub><sup>18</sup> 1.4469, d<sub>4</sub><sup>18</sup> 0.8361; the bromide, b<sub>4</sub> 122°, n<sub>D</sub><sup>18</sup> 1.4605, d<sub>4</sub><sup>18</sup> 1.001; *Et* hexahydrofarnesylacetoacetate, b<sub>33</sub> 175-8°, n<sub>D</sub><sup>18</sup> 1.4184, d<sub>4</sub><sup>18</sup> 0.9014; decompn. with EtOH-KOH gives III, b<sub>3</sub> 142-3°, n<sub>D</sub><sup>18</sup> 1.4 35, d<sub>4</sub><sup>19</sup> 0.8403; semicarbazone, m. 70-70.5°. The acid fraction was sepd. by distn. of the Me est.rs; the 1st fraction, whose ester b<sub>785</sub> 139-41°, is γ-methylvaleric acid. The 2nd fraction is 4,8-dimethylnonic acid, whose ester b<sub>3</sub> 105-8° and amide m. 80-1°; this acid was synthesized by oxidizing hexahydro-ψ-ionone with CrO<sub>3</sub>. The 3rd fraction contains 3,7,11-trimethyltetradecanoic acid(?), whose ester b<sub>3</sub> 145-8°. In certain expts. a compd., possibly 4,8-dimethylnonaldehyde, whose semicarbazone m. 115-6°, is obtained. These results indicate that there may be at least 3 isomers of I, Me<sub>2</sub>C:CHCH<sub>2</sub>(CH<sub>2</sub>CMc:CHCH<sub>2</sub>)<sub>2</sub>CH<sub>2</sub>CMc:CHMe, Me<sub>2</sub>C:CHCH<sub>2</sub>(CH<sub>2</sub>C(CH<sub>3</sub>)CH<sub>2</sub>CH<sub>2</sub>)<sub>2</sub>CH<sub>2</sub>CMc:CHMe, and Me<sub>2</sub>C:CHCH<sub>2</sub>

CH : CMe(CH<sub>2</sub>)<sub>2</sub>CH : CMe(CH<sub>2</sub>)<sub>2</sub>CH : CMe(CH<sub>2</sub>)<sub>2</sub>CH : CMe(CH<sub>2</sub>)<sub>2</sub>CMe : CHMe. Evidence for these formulas is presented. C. J. WEST

**Hydrogenation of phenanthrene.** II. G. SCHROETER, HANS MÜLLER AND JOSEPH Y. S. HUANG. *Ber.* 62B, 645–58 (1929); cf. *C. A.* 19, 1274.—It was shown in the 1st paper that the hydrogenation of anthracene leads rapidly in only 3 phases through *ms*-dihydroanthracene and tetracene to the stable oethracene while with phenanthrene (I) it was possible to isolate tetanthrene (II) and octanthrene (III) but not *ms*-dihydrophenanthrene (IV). To be sure, there is described in the literature under this name a compd. (V), m. 95°, capable of forming a picrate, m. 137°, but this has been found to be not a chem. individual but I contaminated with some II. The true IV can be obtained, along with II or with II and III, by partial hydrogenation of I. II can readily be removed from this mixt. because it is the only component which forms a picrate, and the III and IV, which boil at almost the same temp., can be sepd. through their SO<sub>3</sub>H derivs.; III forms a mono-SO<sub>3</sub>H acid quite difficultly sol. in H<sub>2</sub>SO<sub>4</sub> while IV yields an easily sol. di-SO<sub>3</sub>H acid, hydrolysis of which gives pure IV. Although this ready formation of a di-SO<sub>3</sub>H acid and the non-formation of a picrate were already strong evidence that IV is the true *ms*-dihydro compd., its identity was further established by synthesizing the IV from (*o*-BrCH<sub>2</sub>C<sub>6</sub>H<sub>4</sub>)<sub>2</sub> and Na. In the 1st paper II was assigned, without absolute proof, the 5,6,7,8-tetrahydro structure because of its strong tendency to picrate formation and because it is also formed by partial dehydrogenation of III. This, too, has now been confirmed by synthesis. Oxidation of II does not give a quinone, as does tetracene, but, with CrO<sub>3</sub>, 5-tetanthrenone (VI) with some I, and, with KMnO<sub>4</sub>, in Me<sub>2</sub>CO, both VI and the 8-isomer (VII). VII and VI are also obtained by gently warming 2- and 1-C<sub>10</sub>H<sub>7</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>COCl (VIII and IX), resp. The corresponding  $\gamma$ -1- and 2-naphthylbutyric acids (X and XI) were prepd. as follows: C<sub>10</sub>H<sub>7</sub> and ClCH<sub>2</sub>COCl heated with a little P<sub>2</sub>O<sub>5</sub> give 84%  $\alpha$ - and 16%  $\beta$ -C<sub>10</sub>H<sub>7</sub>COCH<sub>2</sub>Cl (XII and XIII) (sepd. through their picrates or by conversion with NaOCl into a mixt. of  $\alpha$ - and  $\beta$ -C<sub>10</sub>H<sub>7</sub>CO<sub>2</sub>H and sepn. of the latter through their Ca salts). With NaCH(CO<sub>2</sub>Me)<sub>2</sub> the chlorides yield the corresponding *di*-Me  $\alpha$ - and  $\beta$ -naphthacylmalonates (XIV and XV), which on hydrolysis to the free acids (XVI and XVII) and elimination of CO<sub>2</sub> give  $\beta$ -1- and 2-naphthylpropionic acids (XVIII and XIX) and these with Zn and HCl form X and XI, thus establishing the structure of VI and VII and, consequently, of II. The peculiar transformation of IV into II, involving a migration of 2 H atoms from the middle to 1 of the outer rings, can also be effected with Na and AmOH, for IV was also obtained along with II in the partial hydrogenation of I by this means; the V obtained at the same time can be sepd. by fractional crystn. from alc. into I and II. For the catalytic hydrogenation the com. I must be freed from fluorene (which is still present to the extent of about 10% in the purified com. product) by fractionation *in vacuo* and then treated with Na until it gives no test for S; 89 g. of a I so treated and hydrogenated in a tetralin-catalyst mixt. under 20 atm. H<sub>2</sub> pressure at 150–80° until it has absorbed 1.4 mols. H<sub>2</sub> (about 25 mins.) gives 86 g. oil, b<sub>11</sub> 170–80°, which yields 119 g. II picrate and 31 g. of a mixt., b<sub>11</sub> 167–70°, of III and IV; from 18 g. of this mixt. with concd. H<sub>2</sub>SO<sub>4</sub> at 80° are obtained 5 g. octanthrenesulfonic acid, 15.2 g. *di*-Na *ms*-dihydrophenanthrenedisulfonate and 9.6 g. of more easily sol. stereoisomeric Na salts; the less sol. salts with PCl<sub>5</sub> give 14 g. of a disulfonyl chloride, m. 263° (decompn.), the more easily sol. salts a chloride, m. 184.5°. The chlorides, hydrolyzed back to the Na salt and heated at 200° with fuming HCl, give IV, b<sub>15</sub> 168–9°, m. 34.5–5°, can easily be supercooled, d<sub>4</sub><sup>14</sup> 1.0953, d<sub>4</sub><sup>20</sup> 1.0757, M 59.360, 59.979, 61.369, 62.941 for  $\alpha$ , D,  $\beta$  and  $\gamma$  at 14.7°, E<sub>Z</sub> 1.308, 1.405, 53%, 53% for  $\alpha$ , D,  $\beta$ - $\alpha$ , and  $\gamma$ - $\alpha$ . Picrate of II, red-yellow, m. 111°. II, m. 33–4°, b<sub>11</sub> 173° (v. Auwers and Kraul's prepn., m. 14°, was evidently impure), d<sub>4</sub><sup>10</sup> 1.0061, M 59.116, 59.752, 61.317, 62.805 for  $\alpha$ , D,  $\beta$  and  $\gamma$  at 40°, E<sub>Z</sub> 0.885, 0.991, 62%, 68% for  $\alpha$ , D,  $\beta$ - $\alpha$  and  $\gamma$ - $\alpha$ . VI, m. 69°; *semicarbazone*, m. 225° (decompn.); *oxime*, m. 172–3°; *picrate*, m. 101–2°. VII (1.2 g., together with 2.7 g. VI and 10 g. unchanged II, from 18.2 g. II), m. 96–7°; *semicarbazone*, m. 247° (decompn.); *oxime*, m. 165–6°; *picrate*, m. 106–7°. With boiling aq. KMnO<sub>4</sub>, II gives phthalic and mellophanic acids.  $\alpha$ -Naphthacyl chloride (XII), m. 40–1.5°, b<sub>12</sub> 203°; *picrate*, m. 94°.  $\beta$ -Isomer (XIII), m. 67–8°; *picrate*, m. 90–1°. XIV, sirup (14 g. from 10 g. XII); XVI (9.5 g.) gives at 130–40° 7 g. XVIII, m. 131–2°, which yields 4.2 g. X, m. 106–7°, b<sub>15</sub> 217°, and this through the chloride gives 2.5 g. VII. XV (6 g. from 6.1 g. XIII), m. 115.5°; 5 g. yields 4 g. XVII, m. 162°, titrates in H<sub>2</sub>O with Me orange as a monobasic acid, in alc. with phenolphthalein normally as a dibasic acid, yields 3.7 g. XIX, m. 174°, 3.3 g. of which gives 2.5 g. XI, m. 94–5°, and 2.4 g. of the XI yields 1.5 g. VI. C. A. R.

**Heterocyclic systems containing selenium. I. Cycloselenobutane (tetrahydro-selenophene).** GILBERT T. MORGAN AND FRANCIS H. BURSTALL. Teddington, Middlesex. *J. Chem. Soc.* 1929, 1096-1103.— $\text{Br}(\text{CH}_2)_4\text{Br}$  and  $\text{Na}_2\text{Se}$  in excess, heated at  $80^\circ$  in a current of  $\text{H}$  (aq. soln.) for 4 hrs., give 75% of cycloselenobutane (I),  $b_{770}$   $90-1^\circ$ ,  $b_{770}$   $135-6^\circ$ ,  $d_4^{25}$  1.484,  $d_4^{25}$  1.5060 — 0.001354t,  $n_D^{25}$  1.5510,  $\gamma^{18}$  40.40; it has a very pungent and somewhat unpleasant odor, is volatile with steam or in the vapors of  $\text{EtOH}$  and  $\text{Et}_2\text{O}$ ; it is oxidized by fuming  $\text{HNO}_3$  and aq.  $\text{KMnO}_4$ ; mercurichloride, m.  $146^\circ$ . Passing  $\text{Cl}$  into I in  $\text{CCl}_4$  gives cycloselenobutane 1,1-dichloride (II), m.  $88-9^\circ$ ; dibromide (III), yellow, m.  $92^\circ$ ; perbromide,  $\text{C}_4\text{H}_8\text{SeBr}_2$ , Br<sub>2</sub>, crimson, decomp. in the air or when heated, giving III; diiodide, purplish black, m.  $99-100^\circ$ . III and excess  $\text{Ag}_2\text{O}$  in  $\text{H}_2\text{O}$  give the 1,1-dihydroxide (IV), hygroscopic; the aq. soln. is neutral to litmus,  $\text{HBr}$  regenerates III. With 0.5 the theory of  $\text{Ag}_2\text{O}$  or by mixing equimol. proportions of III and IV, there results the 1-hydroxy-1-bromide, decomp. slowly on keeping, or on heating at  $99-100^\circ$ ; the aq. soln. is strongly acidic. 1-Hydroxy-1-chloride, decomp.  $116^\circ$ . Cold dil. aq. solns. of II and  $\text{H}_2\text{PtCl}_6$  give the 1-chloroplatinate, yellow, decomp.  $230^\circ$ ; excess of II gives bis-1-chlorocycloselenobutane 1-chloroplatinate, orange, m.  $179^\circ$  (decompn.). Equal parts of I and  $\text{MeI}$  give the 1-methiodide, sublimes slowly at  $150^\circ$ , m. (sealed tube)  $174^\circ$ .  $\text{Br}(\text{CH}_2)_4\text{Br}$  and I give 1- $\delta$ -bromobutylcycloselenobutane 1-bromide, m.  $65-6^\circ$ . A mixt. of I,  $\text{Br}(\text{CH}_2)_3\text{Br}$  and  $\text{H}_2\text{O}$ , heated at  $90^\circ$  in a sealed tube, gives tetramethylene- $\alpha,\delta$ -biscycloselenobutane 1,1'-dibromide, m.  $95-6^\circ$ .  $\text{KSeCN}$  and  $\text{Br}(\text{CH}_2)_4\text{Br}$  in  $\text{Me}_2\text{CO}$ , heated several hrs., give nearly quant. tetramethylene  $\alpha,\delta$ -diselenocyanate, m.  $40^\circ$ , decomp. slowly on keeping; with  $\text{EtONa}$  this gives cyclo-tetramethylene diselenide, yellow, m.  $41-2^\circ$ ; strongly heated, it gives I;  $\text{Br}$  in  $\text{CHCl}_3$  gives III; warm  $\text{HNO}_3$  (1:1) gives  $\alpha,\delta$ -tetramethylenediseleninic acid dinitrate, decomp.  $136^\circ$ .

C. J. WISE

$\Delta^1$ - and  $\Delta^2$ -pyrazolines. K. v. AUWERS AND E. CAUER. *Ann.* 470, 284-312 (1929); cf. Buchner, *Ann.* 273, 214 (1893); v. Pechmann, *Ber.* 33, 3590, 3594, 3597 (1900).— $\text{CH}_2:\text{CHCO}_2\text{Et}$  and  $\text{CH}_2\text{N}_2$  in abs.  $\text{Et}_2\text{O}$ , allowed to stand 2 hrs., give Et pyrazoline-3-carboxylate, m.  $73-4^\circ$ ,  $d_4^{20}$  1.0766,  $n$  1.47731, 1.48288, 1.49799 for  $\alpha$ ,  $\text{He}$  and  $\beta$  at  $100.2^\circ$ ; oxidation with  $\text{Br}$  in  $\text{Et}_2\text{O}$  gives Et pyrazole-3(5)-carboxylate, m.  $157-8^\circ$ .  $\text{CH}_2:\text{CHCO}_2\text{Me}$  and  $\text{MeCHN}_2$  give Me 5-methylpyrazoline-3-carboxylate,  $b_{12}$   $138^\circ$ , m.  $42.5-4^\circ$ ,  $d_4^{27.3}$  1.1044,  $n$  1.49094, 1.49757, 1.51207 at  $57.3^\circ$ ; 1-Ac deriv., pale yellow-green,  $b_{12}$   $140^\circ$ ; 1-carbethoxy deriv., m.  $84-5.5^\circ$ ; 1-Me deriv.,  $b_{12}$  about  $105^\circ$ .  $\text{AcCH}:\text{CHCO}_2\text{Me}$  and  $\text{N}_2\text{H}_4$ ,  $\text{HCl}$  in dil.  $\text{EtOH}$  give, after 24 hrs., Me 3-methylpyrazoline-5-carboxylate,  $b_{12}$   $117^\circ$ ,  $d_4^{19.4}$  1.1400,  $n$  1.47340, 1.47660, 1.48411 at  $19.4^\circ$ , 1-phenylurethan, m.  $117.5-8.5^\circ$ ; 1-Ac deriv., m.  $52.5-3^\circ$ ; 1-carbethoxy deriv., m.  $53-4.5^\circ$ .  $\text{AcCH}:\text{CHCO}_2\text{Me}$  yields a carbethoxyhydrazone, m.  $127-7.5^\circ$ , which gives the above carbethoxy deriv. on closing the ring. In the attempted prepn. of Me 1,3-dimethylpyrazoline-5-carboxylate a small amt. of an oil,  $b_{11}$   $104^\circ$ , was obtained, which turned deep brown in the air.  $\text{MeCH}:\text{CHCO}_2\text{Me}$  and  $\text{CH}_2\text{N}_2$  give Me 4-methylpyrazoline-3-carboxylate, m.  $33-5^\circ$ ,  $d_4^{58.6}$  1.1156,  $n$  1.49518, 1.50105, 1.51762 at  $56.6^\circ$ , Bz deriv., yellow, m.  $89-90^\circ$ .  $\text{MeCHN}_2$  gives Me 4,5-dimethylpyrazoline-3-carboxylate,  $b_{14}$   $139-40^\circ$ ,  $d_4^{21.4}$  1.0994,  $n$  1.50046, 1.50575, 1.52053 at  $21.4^\circ$ ; 1-phenylurethan, m.  $111-3^\circ$ .  $\text{PhCHN}_2$  gives a product which decomp. on distn.; oxidation of the crude product with  $\text{Br}$  gives, after sapon., 4-methyl-3(5)-phenylpyrazole, crystg. with 1  $\text{H}_2\text{O}$ , m.  $234-6^\circ$  (decompn.).  $\text{PhCH}:\text{CHCO}_2\text{Et}$  and  $\text{CH}_2\text{N}_2$  give Et 4-phenylpyrazoline-3-carboxylate, m.  $100-100.5^\circ$ ; Et 4-phenylpyrazole-3(5)-carboxylate, m.  $162-2.5^\circ$ .  $\text{PhCH}:\text{CHCO}_2\text{Am}$  and  $\text{CH}_2\text{N}_2$  give Am 4-phenylpyrazoline-3-carboxylate, m.  $109-11^\circ$ . 3-Phenylpyrazoline-5-carboxylic acid gives a 1-Ac deriv., m.  $216-7.5^\circ$ , a 1-NO deriv., light brown, m.  $133.5^\circ$  (decompn.), and a Me ester, yellow,  $b_{12}$   $178^\circ$ ,  $d_4^{17.6}$  1.1817,  $n$  1.57188, 1.57937, 1.59858 at  $17.5^\circ$  (phenylurethan, m.  $136.5-7.5^\circ$ ); oxidation with  $\text{Br}$  gives 4-bromo-3-phenylpyrazole-5-carboxylic acid, light brown, m.  $256-7^\circ$ . Di-Me maleate and  $\text{MeCHN}_2$  give di-Me 5-methylpyrazoline-3,4-dicarboxylate,  $b_2$   $145-53^\circ$ ,  $d_4^{60.4}$  1.1628,  $n$  1.47944, 1.48415, 1.49657 at  $68.4^\circ$ ; oxidation and sapon. give 5-methylpyrazole-3,4-dicarboxylic acid, m.  $229-30^\circ$ . Di-Me citraconate and  $\text{CH}_2\text{N}_2$  give a mixt. of 3 compds.; the fraction  $b_{14}$   $104^\circ$  is di-Me 1-methyltrimethylene-1,3-dicarboxylate,  $d_4^{20}$  1.112,  $n$  1.44425, 1.44680, 1.45315, 1.45863 at  $19.5^\circ$  for  $\alpha$ ,  $\text{He}$ ,  $\beta$  and  $\gamma$ , the free acid, m.  $141-2.5^\circ$ ; excess of  $\text{AcCl}$  gives the anhydride,  $b_{11}$   $126-7^\circ$ ,  $d_4^{20}$  1.234,  $n$  1.46466, 1.46756, 1.47461 at  $21.2^\circ$  for  $\alpha$ ,  $\text{He}$  and  $\beta$ . The fraction  $b_{12}$   $148^\circ$  is di-Me 3-methyl- $\Delta^1$ -pyrazoline-3,4-dicarboxylate,  $d_4^{21.7}$  1.1973,  $n$  1.46167, 1.46508, 1.47164, 1.47778 for  $\alpha$ ,  $\text{He}$ ,  $\beta$  and  $\gamma$  at  $21.7^\circ$ ; this does not react with  $\text{PhNCO}$ ; oxidation with  $\text{Br}$  gives

3(5)-methylpyrazole-4-carboxylic acid, m. 228°; with HCl in abs. Et<sub>2</sub>O there results the HCl salt, m. about 120°, of *di*-Me 5-methylpyrazoline-4,5-dicarboxylate, *b*<sub>20</sub> 172°, *d*<sub>40</sub> 1.2299, *n* 1.47594, 1.47933, 1.48615, 1.49263 at 20°. The fraction *b*<sub>12</sub> 178° is *di*-Me 4-methylpyrazoline-3,4-dicarboxylate, m. 58–60°, *d*<sub>4</sub><sup>66</sup> 1.1980, *n* 1.48415, 1.48910, 1.50129 for  $\alpha$ ,  $\beta$  and  $\beta$  at 65.8°; phenylurethan, m. 148–9°. *Di*-Me pyrocinchonate and CH<sub>3</sub>N<sub>2</sub> give *di*-Me 3,4-dimethyl- $\Delta^1$ -pyrazoline-3,4-dicarboxylate, *b*<sub>11</sub> 149°, m. 49–51°, *d*<sub>4</sub><sup>17</sup> 1.1750, *n* 1.46393, 1.46735, 1.47349 at 17°. HCl in Et<sub>2</sub>O gives the HCl salt, m. about 160°, of *di*-Me 4,5-dimethylpyrazoline-4,5-dicarboxylate, m. 71–3°, *d*<sub>4</sub><sup>99.7</sup> 1.1242, *n* 1.44618, 1.44966, 1.45509 at 99.7°; phenylurethan, m. 136–7°. PhCH:CMcCO<sub>2</sub>Me and CH<sub>3</sub>N<sub>2</sub> give a PhMeC:CMcCO<sub>2</sub>Me, probably a mixt. of *cis*- and *trans*-forms.

C. J. WEST

**Aminobenzothiazoles. XII.** The mobility of 1-amino-3,5-dimethylbenzothiazole. A case of complete reactivity in the aminothiazole form. ROBERT F. HUNTER AND WM. E. PRIDE. *J. Chem. Soc.* 1929, 943–6; cf. *C. A.* 23, 835. —*m*-Xylylthiocarbamide (I) and Br in CHCl<sub>3</sub> give the intermediate *Br* compd., C<sub>9</sub>H<sub>10</sub>N<sub>2</sub>Br<sub>2</sub>S, orange, m. 273° (decompn.), reduced by SO<sub>2</sub> in H<sub>2</sub>SO<sub>4</sub> to 1-amino-3,5-dimethylbenzothiazole (II), m. 139–40°. I and Ac<sub>2</sub>O at 75° give the labile *Ac* deriv. (III), m. 121–2°, which changes with ease to the stable form (IV), m. 181–2°. III gives 1-imino-2-acetyl-3,5-dimethyl-1,2-dihydrobenzothiazole, m. 118°; this is unchanged after refluxing with 60% H<sub>2</sub>SO<sub>4</sub> for 3 hrs. but with 30% HCl for 3 hrs. it yields II. IV and Br in CHCl<sub>3</sub> give 1-acetamidobenzothiazole, m. 167° (decompn.), reduced by SO<sub>2</sub> to the acetamidobenzothiazole, m. 259–60°, identical with the *Ac* deriv. of II. Methylation of II with MeI gives the *HI* salt, silvery green luster, m. 274° (decompn.), of 1-amino-2,3,5-trimethyl-1,2-dihydrobenzothiazole, m. 105–6°, whose *Ac* deriv., m. 186°. The quantity of II methylated in C<sub>6</sub>H<sub>6</sub> is inappreciable in the 1st few hrs.; after 16 hrs. unchanged II and an *i*-free compd., m. 156–7°, are the only products. *sym*-m-Xylylthiocarbamide, m. 152°; Br in CHCl<sub>3</sub> gives the intermediate *Br* compd., m. 129°, which is reduced to 1-methylamino-3,5-dimethylbenzothiazole, m. 124–5°; *Ac* deriv., m. 156–7°; *HI* salt, m. 225–7° (decompn.). II and Me<sub>2</sub>SO<sub>4</sub> in C<sub>6</sub>H<sub>6</sub> give a methosulfate, m. 216–7°; decompn. with 20% KOH gives II.

C. J. WEST

**Styrylpyrylium salts. XI.** Determination of the reactive group in ketones of the type CH<sub>3</sub>COCH<sub>2</sub>R by means of the benzo- $\beta$ -naphthaspiropyran color change. ISIDOR M. HEILBRON and FRANCIS IRVING. Imp. College Sci. Tech., London. *J. Chem. Soc.* 1929, 936–43; cf. *C. A.* 22, 4526. —Benzo- $\beta$ -naphthaspiropyran substituted in the 3-position ionize on being heated in inert solvents, giving colored solns., while the isomeric 3'-substituted compds. fail to show this phenomenon; this reaction can therefore be utilized in deciding between the structures *o*-HOC<sub>6</sub>H<sub>4</sub>CH:CHCOCH<sub>2</sub>R and *o*-HOC<sub>6</sub>H<sub>4</sub>CH:CH CRAc. The use of this reaction is shown in the case of the ketone of Dickinson (*C. A.* 21, 80) from *o*-HOC<sub>6</sub>H<sub>4</sub>CHO and PhCH<sub>2</sub>COMe. 2-Hydroxy- $\alpha$ -phenylstyryl Me ketone and 2,1-C<sub>10</sub>H<sub>6</sub>(OH)CHO in abs. EtOH, satd. with dry HCl, or a cold soln. of *o*-HOC<sub>6</sub>H<sub>4</sub>CHO and PhCH<sub>2</sub>COMe in abs. EtOH, satd. with dry HCl and then treated with 2,1-C<sub>10</sub>H<sub>6</sub>(OH)CHO give 3-phenylbenzo- $\beta$ -naphthaspiropyran, m. 208–9° to a purple liquid which loses its color on cooling; the colorless soln. in C<sub>6</sub>H<sub>6</sub>Me<sub>2</sub> becomes faintly colored on heating; in PhNO<sub>2</sub> a strong reddish blue color is produced. D's compd., m. 145°, from *o*-MeOC<sub>6</sub>H<sub>4</sub>CHO and PhCH<sub>2</sub>COMe, is probably not *o*-MeOC<sub>6</sub>H<sub>4</sub>CH:CHCOCH(Ph):CHC<sub>6</sub>H<sub>4</sub>OMe (*o*), since an isomeric compd., pale yellow, C<sub>20</sub>H<sub>12</sub>O<sub>2</sub>, m. 180°, results from the condensation of these components with dry HCl at –5°; 1 of these, probably the former, may have a cyclopentenone structure. *Bz*II and AcCH(CHMe<sub>2</sub>)CO<sub>2</sub>Et with NaOH give  $\gamma$ -benzylidene- $\alpha$ -isopropylacetoacetic acid, m. 134° (decompn.); heating with Cu at 130–40° for 1.5 hrs. gives styryl iso-Bu ketone. *o*-HOC<sub>6</sub>H<sub>4</sub>CHO and iso-BuCOMe with EtOH-NaOH give 2-hydroxystyryl iso-Bu ketone, yellow, m. 104°; with 2,1-C<sub>10</sub>H<sub>6</sub>(OH)CHO this gives 3'-isopropylbenzo- $\beta$ -naphthaspiropyran, pale yellow, m. 118°, which gives colorless solns. in veratrole and Ph<sub>2</sub>O. 3-Isopropylidene- $\beta$ -naphthaspiropyran, m. 204°, gives purple solns. in boiling C<sub>6</sub>H<sub>6</sub>Me<sub>2</sub> or veratrole. 2-Hydroxystyryl nonyl ketone gives 3'-octylbenzo- $\beta$ -naphthaspiropyran, m. 101–2°, which gives colorless solns. in Ph<sub>2</sub>O and C<sub>6</sub>H<sub>6</sub>Me<sub>2</sub>. Me nonyl ketone gives 3-octylidene- $\beta$ -naphthaspiropyran, m. 157°, which gives a purple soln. in boiling C<sub>6</sub>H<sub>6</sub>Me<sub>2</sub>. **XII. Spiropyrans** derived from 9-methyl- and 9-ethylxanthylum salts. FRANCIS IRVING. *Ibid* 1093–5. —9-Methylxanthanol (I), 2,1-C<sub>10</sub>H<sub>6</sub>(OH)CHO and dry HCl give xantha- $\beta$ -naphthaspiropyran, m. 201° to a deep red liquid; in boiling Ph<sub>2</sub>O a deep strawberry color develops. *o*-HOC<sub>6</sub>H<sub>4</sub>CHO and I with HCl give benzo-xantha- $\beta$ -piropyran (II), m. 154°. 9-Ethylxanthanol and 2,1-C<sub>10</sub>H<sub>6</sub>(OH)CHO give

3'-methylxantha- $\beta$ -naphthaspiropyran (III), m. 271°. Solns. of II and III in Ph<sub>2</sub>O remain colorless when heated. C. J. WEST

**Methoxy derivatives of thioxanthone.** KENNETH C. ROBERTS AND SAMUEL SMILES. *J. Chem. Soc.* 1929, 863-72.—2-HSC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H, 4-IC<sub>6</sub>H<sub>4</sub>OMe, K<sub>2</sub>CO<sub>3</sub> and Cu(OAc)<sub>2</sub> in AmOH, boiled 16 hrs., give 90% of 2'-carboxy-4-methoxydiphenyl sulfide (I), m. 232°. In the reduction of 2,4-O<sub>2</sub>N(MeO)C<sub>6</sub>H<sub>3</sub>Me with Sn and HCl there results a small amt. of a chloro-4-methoxy-*o*-toluidine, m. 112°. 2-Iodo-4-methoxytoluene, pale yellow, b. 252-3°; with 2-HSC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H as above, this gives 75% of 2'-carboxy-5-methoxy-2-methyldiphenyl sulfide (II), m. 176-7°. 4-IC<sub>6</sub>H<sub>4</sub>(OMe)<sub>2</sub> gives 2'-carboxy-3,4-dimethoxydiphenyl sulfide (III), m. 212-3°. I and H<sub>2</sub>SO<sub>4</sub> at 15° for 1 hr. give 2-methoxythioxanthone, m. 129; perchlorate, orange; the compd. absorbs dry HCl but the product is unstable. A mixt. of 2-HSC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H, 16 g. 4-ClC<sub>6</sub>H<sub>4</sub>OMe and 150 cc. H<sub>2</sub>SO<sub>4</sub>, stirred 1.5 hrs., gives 8 g. 1-chloro-4-methoxythioxanthone, pale yellow, m. 196°; this does not give a perchlorate or HCl salt; with *p*-H<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>Me and a little AcOK and Cu(OAc)<sub>2</sub> there results the 1-*p*-toluidino deriv., red, m. 133° (HCl salt, yellow). 4-MeOC<sub>6</sub>H<sub>4</sub>Me and 2-HSC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H give 4-methoxy-1-methylthipxanthone, pale yellow, m. 162°, which does not yield a perchlorate. II and concd. H<sub>2</sub>SO<sub>4</sub>, stirred for 1 hr., give 1-methoxy-4-methylthioxanthone, bright yellow, m. 128°; it absorbs 3 mols. HCl, giving a red salt; the crimson perchlorate is relatively stable. 1,4-Dimethoxythioxanthone gives a crimson *di*-HCl salt, a deep red chloroplatinate, a red ferrichloride and a crimson perchlorate. 2-Bromoveratric acid, PhSH, K<sub>2</sub>CO<sub>3</sub> and Cu(OAc)<sub>2</sub> in boiling AmOH for 3.5 hrs. give, after treatment with H<sub>2</sub>SO<sub>4</sub>, 3,4-dimethoxythioxanthone, pale yellow, m. 185°; the perchlorate is orange but the HCl salt was too unstable for examn. *o*-C<sub>6</sub>H<sub>4</sub>(OH)<sub>2</sub> and 2-HSC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H with concd. H<sub>2</sub>SO<sub>4</sub> give 2,3-dihydroxythioxanthone (IV), analyzed as the *di*-Ac deriv., pale yellow, m. 191°; it does not form a boracetate. 1,4-Dihydroxythioxanthone yields a crimson boracetate, decompd. by boiling H<sub>2</sub>O to 1-hydroxy-4-acetoxythioxanthone, yellow, m. 171°; the *di*-Ac deriv., yellow, m. 168°. Methylation of IV or dehydration of III gives 2,3-dimethoxythioxanthone (V), pale yellow, m. 172°; *di*-HCl salt, orange; ferrichloride, orange or chocolate-brown (2V.HfFeCl<sub>4</sub> or V.HfFeCl<sub>4</sub>). 1,2-Dimethoxythioxanthone, yellow, m. 143-4°. 2,3,4-Trimethoxythioxanthone, m. 153-4°; *di*-HCl salt, orange; perchlorate, orange. C. J. WEST

**Polarity of the halogens in solutions of pyridinium and allied dichloriodides.** THOMAS H. READE. *J. Chem. Soc.* 1929, 853-63.—C<sub>5</sub>H<sub>5</sub>NCl<sub>2</sub>I and PhMe<sub>3</sub>NCl<sub>2</sub>I are highly dissociated in H<sub>2</sub>O, the solns. being rich in H ions, Cl ions, HIO and its decompn. products; mol. Cl and I ions are absent. The retarding effect of electrolytes contg. Cl and H ions on the dissocn. of these compds. has been measured. The probability that these are double salts contg. a highly reactive, positively charged I atom is discussed. HIO behaves similarly toward phenolic substances and aromatic amines. The original should be consulted for the detailed discussion. C. J. WEST

**Action of mercuric acetate on phenylcinchoninic acid.** B. CECCHETTI AND E. GODI. Reale Univ. Bologna. *Gazz. chim. ital.* 58, 764-5(1928).—Hg(OAc)<sub>2</sub> (I) in very dil. AcOH added to  $\alpha$ -phenylcinchoninic acid (II) (2 mols.), filtered, washed with EtOH and Et<sub>2</sub>O and dried *in vacuo* over H<sub>2</sub>SO<sub>4</sub>, yields the compd. C<sub>22</sub>H<sub>20</sub>O<sub>2</sub>N<sub>2</sub>Hg, light yellow, decomps. at a high temp. without fusion. It is probably the neutral Hg salt of II, [C<sub>6</sub>H<sub>4</sub>.N:CPh.CH:CCOO]<sub>2</sub>Hg. On the other hand when equimol. parts of I and II

are heated, there is obtained the compd. C<sub>16</sub>H<sub>9</sub>O<sub>2</sub>NHg, decomps. without fusion. It is prob-

ably hydroxymercurio- $\alpha$ -phenylcinchoninic anhydride,  $\text{C}_6\text{H}_4\text{.N:CPh.CH:CCOO.O Hg}$ .

The results are interesting in their analogy to the reaction of Na salicylate and I (cf. *Gazz. chim. ital.* 32, 2(1902)). C. C. DAVIS

**Preparation of quinaldinic acid.** THOMAS W. J. TAYLOR. Dyson Perrins Lab., Oxford. *J. Chem. Soc.* 1929, 1110-1.—In the prepn. of quinaldinic acid by Reissert's method (*Ber.* 38, 1610(1905)) the tedious operation of removing the Cu with H<sub>2</sub>S may be avoided by taking advantage of the low soly. of the Na salt in cold NaOH. The Cu salt is boiled with about 2 N NaOH until all the Cu is present as oxide and the hot soln. filtered; the Na salt, crystg. with 1.5 H<sub>2</sub>O, seps. in 85% yield on cooling. At room temp. the Na salt is about 40 times less sol. in 1.5 N NaOH than it is in H<sub>2</sub>O. The acid is obtained by adding the theoretical amt. of HCl to the aq. soln. of the Na salt. C. J. WEST

**The Doebner reaction. VII. Syntheses with  $\beta$ -aminoanthracene.** R. CILSA AND L. MUSAJO. *Gazz. chim. ital.* 59, 70-4(1929); cf. C. and Cremonini, *C. A.* 22, 2565.—BzH (5.5 g.) and  $\beta$ -aminoanthracene (10 g.) suspended in EtOH (200 cc.), refluxed

to carbonaceous products. With  $\text{PhHNNH}_2$  and with  $\text{Na}_2\text{S}_2\text{O}_4$ , alk. solns. of VI become an intense blue, but this disappears on oxidation, *e. g.*, by exposure to the air. Suspended in concd.  $\text{HCl}$ , VI and  $\text{SnCl}_4$  give an intense blue color, but no definite products could be purified. The impure products gave an intense blue color in concd.  $\text{H}_2\text{SO}_4$ .

C. C. DAVIS

**Merquinoid derivatives of 9,10-dihydrophenarsazine.** I. G. RASUVAYEV. *Ber. 62B*, 605-16(1929); *J. Russ. Phys.-Chem. Soc.* 61, 13-28(1929).—(The notation with  $\text{N} = 9$  and  $\text{As} = 10$  is used.) Wieland called attention to a reaction characteristic of derivs. of dihydrophenarsazine (I), *viz.*, an intense red color of their solns. in  $\text{H}_2\text{SO}_4$  which he explained on the basis of halochromism. There is nothing in the literature to show whether other acids also produce this color. R. has now found that the oxide of I dissolves in  $\text{HClO}_4$  with red, in fused  $\text{ClCH}_2\text{CO}_2\text{H}$  with green color (changing to blue on standing) and in  $\text{Cl}_3\text{CCO}_2\text{H}$  with green color. 10-Chloro(or bromo)-9,10-dihydrophenarsazine, the oxide, the  $\text{MeO}$  deriv., trisdihydrophenarsazinamine, as well as the acetate and sulfate all dissolve (relatively little) in cold  $\text{HCO}_2\text{H}$  with faint yellow color changing on warming to an extraordinarily intense red which on cooling, especially with shaking, rapidly disappears and on warming appears again. Here halochromism as an explanation of the color is excluded, as is also dissocn. into the free phenarsazine (Wieland), since the color is produced at relatively low temps. (heating in  $\text{HCO}_2\text{H}$  contg.  $\text{Me}_2\text{CO}$ ) and the colored soln. is not sensitive to water but is very sensitive to atm. O and is decolorized with absorption of O. A careful study has shown that when the oxide, the  $\text{Me}$  ether or the acetate is dissolved in cold  $\text{HCO}_2\text{H}$ , there is

formed the corresponding formate,  $\text{C}_6\text{H}_4 \begin{array}{c} \text{AsR} \\ \diagup \quad \diagdown \\ \text{NH} \end{array} \text{C}_6\text{H}_4$  (II,  $\text{R} = \text{O}_2\text{CH}$ ), which, boiled

in  $\text{Me}_2\text{CO}$  or alc. alone, gives no color but on addn. of  $\text{HCO}_2\text{H}$  develops an intense red color. This intense color is readily produced by heating a  $\text{HCO}_2\text{H}$  soln. of the sulfate and chloride ( $\text{R} = \text{Cl}$ ), with considerably greater difficulty from the bromide, the iodide gives no color at all. Decolorization of these solns. with air regenerates the original salt. When the color begins,  $\text{CO}_2$  is evolved, indicating that the  $\text{HCO}_2\text{H}$  decomps. into  $\text{CO}_2 + \text{H}_2$ , the latter being used up in reducing the II and forming the intensely colored deriv. This reduction can be catalyzed by adding Pt sponge in the cold; even more effective is H itself. The color is also produced by other reducing agents ( $\text{SnCl}_2$  or Zn and  $\text{AcOH}$ ). From the amt. of  $\text{CO}_2$  liberated when the  $\text{HCO}_2\text{H}$  soln. is heated, it can be calcd. that 1 atom H is used up per mol. of II, which would correspond to a quinhydrone structure for the colored product, but such a structure fails to explain a no. of the properties of the colored soln.: its distinctly unsatd character (it adds O, Cl, Br, I, NO and  $\text{NO}_2$ ) and its quite high elec. cond. All of these properties point to the presence of radicals; of the possible formulas, R. gives the preference

to the merquinoid, half-free radical  $\left[ \text{C}_6\text{H}_4 \begin{array}{c} \vdots \\ \text{AsH} \\ \diagup \quad \diagdown \\ \text{NH} \end{array} \text{C}_6\text{H}_4 \right] \text{X}$  (III), as the absorption

spectrum shows a broad band beginning in the green part of the spectrum and the colored solns. show a salt-like character; if such solns. (in  $\text{HCO}_2\text{H}$ ,  $\text{AcOH}$ , alc.,  $\text{Me}_2\text{CO}$ ,  $\text{PhOH}$ ) are shaken with  $\text{C}_6\text{H}_6$  or other hydrocarbons, the hydrocarbon layer remains perfectly colorless; on heating the  $\text{HCO}_2\text{H}$  soln. of the II ( $\text{R} = \text{Cl}$ ) the elec. cond. was greatly increased (to about 25% of the cond. of a  $\text{NaCl}$  soln. of the same concn.). One atom of halogen is required to decolorize the III but the product of direct addn. could not be isolated; there was always obtained quant. the II ( $\text{R} = \text{halogen}$ ), irrespective of the nature of X (Cl, Br,  $\text{O}_2\text{CH}$ ,  $\text{HSO}_3$ ) in the III. The H on the As in the III is very loosely held, the original II being regenerated by shaking with O in the cold or by heating with S; 0.5 atom O per mol. III is consumed. 9,10-Dihydrophenarsazine formate, from the oxide in  $\text{Me}_2\text{CO}$  suspension slowly treated with  $\text{HCO}_2\text{H}$  until it dissolves completely, needles unstable in the air, darkens about  $100^\circ$ , then becomes entirely black and finally yellow around  $150^\circ$ . The reduced solns. of the II in  $\text{HCO}_2\text{H}$  add I instantly, yielding the iodide (II,  $\text{R} = \text{I}$ ), intensely red, m.  $222-4^\circ$ . Bromide, intensely yellow, m.  $210^\circ$ . Chloride, m.  $191-3^\circ$ . NO is absorbed only very slowly in  $\text{HCO}_2\text{H}$  alone but rapidly in a mixt. of equal parts of  $\text{EtOH}$  and  $\text{HCO}_2\text{H}$ ; an appreciable amt. is absorbed after the soln. has become decolorized (faintly yellow) and the total amt. absorbed varies greatly in different expts. under the same conditions. The addn. product could not be isolated; the decolorized soln. decomps. very rapidly in the air with formation of a ppt. and appearance of a deep brown color. C. A. R.

23, 3446.—In attempting to explain why  $\text{AsCl}_3$  and  $(2,4\text{-Cl}_2\text{C}_6\text{H}_3)_2\text{NH}$  do not condense to give 2,4,6,8,10-pentachloro-5,10-dihydrophenarsazine, it has been suggested that the compd. might be too unstable to exist. In order to test this, some typical compds. have been subjected to the action of Br; this action, in every case studied, led to the removal of As and the formation of  $\text{Ph}_2\text{NH}$  derivs. 10-Chloro-5,10-dihydrophenarsazine from  $\text{Ph}_2\text{NH}$  and Br in AcOH; this may be the 2,2',4,4'-Br<sub>2</sub> deriv. The bromination was carried out under varying conditions but the product was always the same 10-methyl-5,10-dihydrophenarsazine gave the same tetra-Br deriv. 10-Chloro-2,8-dimethyl-5,10-dihydrophenarsazine gives a tetrabromodi-*p*-tolylamine, m. 161–2°, identical with the compd. from  $(p\text{-MeC}_6\text{H}_4)_2\text{NH}$  and Br. 7-Chloro-7,12-dihydrobenzophenarsazine and Br give a tetrabromophenyl- $\alpha$ -naphthylamine, m. 150°; 12-chloro-7,12-dihydrobenzophenarsazine gives the  $\beta$ -naphthyl deriv., m. 205° (*Ber.* 20, 1170(1887)).  $\text{C}_6\text{H}_4\text{Me}$ , m. 167–70°; 12-chloro-10-methyl-7,12-dihydrobenzophenarsazine gives a Br<sub>2</sub> deriv. of  $\alpha\text{-C}_6\text{H}_4\text{NH}_2$  deriv., m. 165°, of  $\beta\text{-C}_{10}\text{H}_7\text{NHC}_6\text{H}_4\text{Me}(p)$ . Bromination of phenarsazinic acid in boiling AcOH gives 2,4,6,8,10-pentabromo-5,10-dihydrophenarsazine, yellow, m. 275° and a small amt. of the 2,4,6,8-tetra-Br deriv., also obtained by the action of  $\text{H}_2\text{O}_2$  in AcOH upon the penta-Br deriv., m. 294° (decompn.).

**Constitution of sinomenine.** HEIZABURO KONDO AND EIJI OCHIAI. *C. J. WEST* 224 54(1929); cf. *J. Pharm. Soc. Japan* No. 497, 503, 538; *C. A.* 22, 964–5, 4531—et Wils., found in South Japan. I, liberated from the HCl salt with  $\text{Na}_2\text{CO}_3$  and form is also obtained by adding  $\text{NH}_4\text{OH}$  to the aq. soln. of the HCl salt, on standing it reverts to the lower melting form; analysis and mol. wt. indicate the formula  $\text{C}_{19}\text{H}_{23}\text{NO}$ ;  $[\alpha]_D^{26} -70.76^\circ$  (0.2120 g. in 10 cc. EtOH); *HCl* salt, decomp. 231°,  $[\alpha]_D^{17} -6.89^\circ$  (4.1812 g. in 100 cc.  $\text{H}_2\text{O}$ ), crystals with 2  $\text{H}_2\text{O}$ ; *chloroaurate*, amorphous; *methiodide*, m. 251°; *Bz* deriv., by heating I and  $\text{Bz}_2\text{O}$  4 hrs. at 100°, m. 225°,  $[\alpha]_D^{26} -3.37^\circ$  (0.3075 g. in 10 cc. EtOH) (*chloroaurate*); *Me* deriv., from I and  $\text{CH}_3\text{N}_2$ , m. 175° (*HCl* salt, m. 252°; *semicarbazone*, decomp. 250–2°); *oxime*, m. 254° (decompn.); *semicar-*

(I)

(III)

(V)

*bazone*, decomp. 264°. Catalytic reduction of I according to Skita gives the *dihydro* deriv. (II), m. 199°,  $[\alpha]_D^{16} 170.5^\circ$  (0.1756 g. in 15 cc. EtOH); *semicarbazone*, decomp. 207°. *I* and Br in AcOH give 2 *Br* derivs., m. 138° and 205°.  $\text{ClCO}_2\text{Et}$  and KOH give the compd.  $\text{C}_{20}\text{H}_{25}\text{NO}_4\text{Cl}$ , m. 166–83° (decompn.),  $[\alpha]_D^{17} -108.4^\circ$  (0.2265 g. in 12 cc.  $\text{CHCl}_3$ ). Heating I and  $\text{Bz}_2\text{O}$  6 hrs. at 150–60° gives the compd.  $\text{C}_{20}\text{H}_{25}\text{O}_6$ , m. 206°, gives a purple-red color with concd.  $\text{H}_2\text{SO}_4$  and a red-brown color with hot NaOH. Zn distn. of I gives phenanthrene and  $\text{Me}_3\text{N}$ . Reduction of I with amalgamated Zn and HCl gives *desoxytetrahydrosinomenine* (III), m. 150–1°, crystg. with 0.5  $\text{H}_2\text{O}$ ,  $[\alpha]_D^{21} 48.20^\circ$  (0.1774 g. in 15 cc. EtOH); *III* salt, m. 250–1°; *methiodide*, m. 265°; does not react with Co reagents; III is the optical antipode of dihydrothebaccodine (Speyer and Siebert, *C. A.* 15, 3975); a mixt. of the 2, crystd. from  $\text{Me}_2\text{CO}$ , is optically inactive. *III*, *MeI* and KOH, heated until a brown oil seps., gives *des-N-methyl-desoxytetrahydrosinomenine* (IV), m. 140°,  $[\alpha]_D^{21} -41.59^\circ$  (0.1635 g. in 20 cc. MeOH); *methiodide*, hygroscopic; transformed into the chloride and heated with KOH, there results

the *compd.* V, pale yellow, m. 93°,  $[\alpha]_D^{17}$  —181.6° (0.1564 g. in 20 cc. EtOH) and  $\text{Me}_3\text{N}$  V is stable toward cold  $\text{KMnO}_4$  but on boiling a *compd.*, m. 115°, is obtained; V is not changed by boiling with  $\text{Ac}_2\text{O}$  for 15 mins. Reduction of II with Na-Hg gives the *compd.*  $\text{C}_{18}\text{H}_{25}\text{NO}_3$ , m. 92–105° (decompn.),  $[\alpha]_D^{20}$  32.02° (0.1374 g. in 20 cc. EtOH); *methiodide*, m. 268–72°,  $[\alpha]_D^{29}$  23.9° (0.1548 g. in 20 cc. MeOH). This is *des-methoxy-dihydrosinomeninol* and is the optical antipode of the reduction product of dihydrothebainone (*dihydrothebainol*, m. 144°,  $[\alpha]_D^{28}$  —46.2°; *methiodide*, m. 278° (decompn.),  $[\alpha]_D^{29}$  —24.25°), since a mixt. of the 2 is optically inactive. Reduction of I with Na-Hg gives the amorphous *base*,  $\text{C}_{18}\text{H}_{25}\text{NO}_3$ , m. 180°,  $[\alpha]_D^{27}$  —11.24° (0.1424 g. in 20 cc. EtOH). Heating 9 g. Na homoveratrumate and 9 g. *o*-nitroveratrumic aldehyde in 50 cc.  $\text{Ac}_2\text{O}$  50 hrs. at 110–20° gives  $\alpha$ -3,4-dimethoxyphenyl-2-nitro-3',4'-dimethoxycinnamic acid, yellow, m. 191–2°; reduction with  $\text{FeSO}_4$  and  $\text{NH}_4\text{OH}$  gives the 2-amino deriv., yellow, m. 146°; the diazo *compd.* gives a mixt. of 3,4,5,6-tetramethoxyphenanthrene-9-carboxylic acid (VI), m. 234°, and the 3,4,6,7-tetra-MeO deriv., m. 210°. The latter, heated with AcOH 20 hrs. at 250–60°, gives 3,4,6,7-tetramethoxyphenanthrene, m. 124–5°, identical with dimethylsinomenol (cf. Goto, *J. Agr. Chem. Soc. Japan* 2, No. 17).  $\alpha$ -3',4'-Dimethoxy-6'-bromo-2-nitro-3,4-dimethoxycinnamic acid, yellow, m. 216°; 2- $\text{NH}_2$  deriv., yellow, m. 187°; 8-bromo-3,4,5,6-tetramethoxyphenanthrene-9-carboxylic acid, m. 187–8° (decompn.); reduction gives VI. Catalytic reduction of thebainone with Pd gives  $\beta$ -dihydrothebainone, m. 76°,  $[\alpha]_D^{27}$  —83.94° (0.2323 g. in 20 cc. EtOH); picrate, yellow, m. 245°; semicarbazone, m. 199–201° (decompn.). Reduction of dihydrohydroxycodone according to Clemmensen gives dihydrohydroxythebaine, m. 138–9°,  $[\alpha]_D^{25}$  —58.15° (0.1135 g. in 20 cc.  $\text{Me}_2\text{CO}$ ) I (5 g.) and 6.2 g.  $\text{AgNO}_3$  in  $\text{H}_2\text{O}$  give, after 36 hrs., the *nitrate*, decomps. above 280° of dehydrosinomenine, m. 218–20°,  $[\alpha]_D^{12}$  97.38° (0.1222 g. in 30 cc. MeOH). Catalytic reduction (Pd) gives isodihydrosinomenine,  $\text{C}_{19}\text{H}_{25}\text{NO}_4$ , decomps. 271°,  $[\alpha]_D^{24}$  171.16° (0.1579 g. in 20 cc. EtOH); *methiodide*; *oxime*, m. 245–50° (decompn.). This *compd.* also results by the action of  $\text{AgNO}_3$  on II; a 2nd product, insol. in  $\text{Me}_2\text{CO}$ , is apparently  $2\text{C}_{19}\text{H}_{25}\text{NO}_4$ , m. 270°,  $[\alpha]_D^{13}$  113.8° (0.0914 g. in 20 cc. MeOH). Thebaine and  $\text{AgNO}_3$  give  $\psi$ -thebaine,  $\text{C}_{19}\text{H}_{21}\text{NO}_3$ , decomps. 227°,  $[\alpha]_D^{16}$  —339.5° (0.1352 g. in 20 cc.  $\text{Me}_2\text{CO}$ ); semicarbazone, decomps. above 290°; dihydro deriv., m. 270° (decompn.),  $[\alpha]_D^{25}$  —71.77° (0.1045 g. in 20 cc.  $\text{Me}_2\text{CO}$ ).

C. J. WEST

**Strychnine and brucine. VIII. Action of hydriodic acid on strychnidine.** Dihydrostrychnidine (B) and substances derived therefrom. Wm. H. PERKIN, JR., AND ROBERT ROBINSON. *J. Chem. Soc.* 1929, 964–1000.—Strychnidine (25 g.), 100 cc. HI (d. 1.94) and 8 g. P, boiled 24 hrs., give dihydrostrychnidine (B) (I),  $\text{C}_{21}\text{H}_{29}\text{ON}_2$ , softens 145°, m. 151°; it is very sol. in org. solvents and thus difficult to obtain pure; it does not react with  $\text{NH}_4\text{OH}$ , is not reduced by Na and EtOH or electrolytically; it does not yield an Ac deriv. and does not condense with aldehydes. The HCl salt crystallizes with 3 $\text{H}_2\text{O}$ , of which 2 are lost at 100° and then m. 123°; the anhyd salt, m. 144–7°. A soln. of I in dil.  $\text{H}_2\text{SO}_4$  contg. a little  $\text{H}_2\text{SO}_3$  and excess NaI gives di-III salt, which loses HI when boiled with MeOH, giving the mono-III salt, m. 235–40° (decompn.); boiling with  $\text{H}_2\text{O}$  and AgCl gives the HCl salt. I and  $\text{Me}_2\text{SO}_4$  in  $\text{C}_6\text{H}_6$  at 10° give the methosulfate (a); with NaI in warm  $\text{H}_2\text{O}$  there results the methiodide (a) (II), m. 340–5° (decompn.);  $\text{CHCl}_3$  forms an addn. *compd.*, which gradually decomps. in the air and more rapidly over  $\text{H}_2\text{SO}_4$  in *vacuo*; AgCl and  $\text{H}_2\text{O}$  gives the methochloride (a), m. 335–40° (decompn.) with the formation of I. I and  $\text{Me}_2\text{SO}_4$  in warm  $\text{C}_6\text{H}_6$  give the dimethosulfate (A); NaI gives the dimethiodide (A) (III), m. 238–42° (decompn.) and appears to give an addn. *compd.* with  $\text{CHCl}_3$ . The dimethochloride (A) forms a resin which, on heating at 120°, gives methoxymethyltetrahydrostrychnidine (B) (IV), m. 178–80°. The dimethobromide (B) decomps. at about 345°. I and MeI in cold MeOH give II; heating the MeOH soln. 2 hrs. gives a mixt. of II, III and the (B) isomer of III, m. 260–5° (decompn.), purified by repeated crystn. from MeOH. II is easily obtained by digesting the crude dimethiodides with MeOH-KOH. II methiodide (b) is obtained by digesting the dimethiodide (B) with MeOH-KOH, it shrinks at 250° and gradually melts as the temp. rises; it does not combine with  $\text{CHCl}_3$ . The methochloride (b) crystallizes with 2 $\text{H}_2\text{O}$ , lost at 100°; heating with MeOH-KOH at 120–30° gives IV. The methobromide (b) decomps. at 340–5°. I and  $\text{PhCH}_2\text{Cl}$  in boiling PhMe give the benzyl chloride, m. 325° (decompn.), giving a yellow gum, consisting in part of I. Oxidation of I in  $\text{Me}_2\text{CO}$  with  $\text{KMnO}_4$  gives dihydrostrychnine

(B),  $C_{21}H_{24}O_2N_2$  (V), m. about  $196^\circ$ , which yields a sparingly sol. HCl salt, and a HI salt, m.  $350-5^\circ$ ; the *methiodide*, pale yellow, m. about  $365^\circ$  (decompn.); *methochloride*, m.  $370-5^\circ$  (decompn.); *methobromide*, m. about  $375^\circ$  (decompn.); *benzylidene deriv.*, pale lemon-yellow, m.  $270-5^\circ$  (HCl salt). II does not appear to yield an oxime. The  $MnO_2$  ppt., extd. with  $H_2O$ , gives a small amt. of an acid,  $C_{21}H_{21}O_7N_2$ , decomp. about  $205^\circ$ . Hydrolysis of V with EtONa gives *dihydrostrychnic acid* (B), m.  $285^\circ$  (decompn.); HCl salt; at the m. p.  $H_2O$  is eliminated and V formed. V and  $H_2O_2$  give *dihydroxydihydrostrychnic acid*,  $C_{21}H_{28}O_6N_2$ , decomp.  $300-5^\circ$ . Oxidation of dihydrostrychnidine (A) with  $KMnO_4$  in  $Me_2CO$  gives *hydroxydihydrostrychnidine* (A),  $C_{21}H_{24}O_2N_2$ , m. about  $345^\circ$ , isomeric with V. Decompn. of II.MeCl or II.2MeCl with MeOH-KOH, gives a mixt. of *methoxymethyltetrahydrostrychnidine* (B) (VI), m.  $179-80^\circ$ , *methyl- $\psi$ -strychnidine* (B), (VII), m.  $222-5^\circ$ , and *dihydrostrychnidine* (C) (VIII), m.  $132-4^\circ$ . VI is not changed by boiling with  $10\%$   $H_2SO_4$  for 2 hrs. and is not reduced electrolytically. The III salt decomp.  $175-80^\circ$  and then m. again  $235^\circ$  and then again  $325^\circ$ ; at  $250-60^\circ$  MeOH is eliminated, giving II; VI may also be changed into II by boiling with HI and P for 2 hrs. VI yields a *methiodide* (IX), which decomp.  $235-8^\circ$ ; at  $250^\circ$  MeI is lost and VI reformed. The *methochloride* decomp.  $170^\circ$  and gives VI. The *dimethosulfate* is deliquescent; NaI transforms it into the *dimethiodide*, m.  $210^\circ$ , which gives IX with  $25\%$  MeOH-KOH. The  $PhCH_2Cl$  compd. of II and MeOH-KOH at  $150^\circ$  give *methoxybenzyltetrahydrostrychnidine* (B), m.  $126.7^\circ$ . Oxidation of VI with  $KMnO_4$  in  $Me_2CO$  gives *formylmethoxytetrahydrostrychnidine* (B), m.  $154^\circ$ ; this is not hydrolyzed by EtONa, does not react with MeI or BzI but with dil.  $H_2SO_4$  gives *methoxytetrahydrostrychnidine* (B) (X),  $C_{21}H_{26}O_2N_2$ , m.  $150-2^\circ$  (NO deriv., light yellow; MeI gives the HI salt of VI); distn. of the formyl deriv. gives what appears to be a 2nd modification of X, m.  $137^\circ$ , transformed into X by boiling with dil.  $H_2SO_4$ , and therefore probably contaminated with some unchanged formyl deriv. VII yields a *dimethiodide*, m.  $275^\circ$ , decomp.  $280-5^\circ$ ; the *dimethochloride* could not be prepd. VIII is monoclinic,  $a:b:c = 1.037:1.2:\beta = 113^\circ 48'$ , the *dimethiodide*, m.  $265-70^\circ$  (decompn.); the *dimethochloride* is a brittle mass, from which MeCl is eliminated with MeOH-KOH, giving VIII. *Benzylidenestrychnine*, m.  $235-7^\circ$ , from the yellow HCl soln. a sparingly sol. HCl salt seps. *Benzylidenebrucine* crystallizes with difficulty, but the HCl salt crystallizes with  $0.5 H_2O$  as yellow needles. *Strychnidine methochloride* crystallizes with  $2H_2O$  and m.  $370^\circ$  (decompn.). *Strychnidine dimethosulfate* crystallizes in long needles; the *dimethochloride* is a gum. *Strychnidine benzyl chloride*, m.  $330-5^\circ$  (decompn.); with MeOH-KOH this gives *methoxybenzyl-dihydrostrychnidine*, m.  $92-5^\circ$ . Many color reactions are described for these various compds.

C. J. WEST

**Strychnine and brucine.** VIII. R. CIUSA. *Gazz. chim. ital.* **58**, 774-5(1928); cf. C. and Scagliarini, *C. A.* **18**, 3192.—Comments on the relation between expts. of Oxford, Perkin and Robinson (*C. A.* **22**, 430) and their relation to the earlier researches of C. (cf. *Rend. accad. Lincei* **21**, ii, 84; **23**, ii, 480; **28**, ii, 185; *C. A.* **18**, 3192). The existence of an OH group and of a double bond in isostrychnine is now firmly established.

**Higher terpene compounds.** XXXVII. Agathidicarboxylic acid, the crystalline resin acid,  $C_{20}H_{30}O_4$ , of kauri, hard and soft Manila copals. L. RUZICKA AND J. R. HOSKING. *Ann.* **469**, 147-92(1929); cf. *C. A.* **23**, 3455.—The isolation of the  $Et_2O$ -sol. cryst. resin acids from the above copals by the method of Horrmann and Kroll (*Arch. Pharm.* **265**, 214(1927)) and careful fractionation of the product with  $(NH_4)_2CO_3$ ,  $Na_2CO_3$  and NaOH are described. From each copal is isolated the same cryst. dibasic acid,  $C_{20}H_{30}O_4$ , m.  $203-4^\circ$ ,  $[\alpha]_D^{25} 52-56^\circ$  in EtOH, for which the name *agathidicarboxylic acid* (I) is suggested. The various dibasic acids isolated from different copals are probably more or less impure forms of this acid. By a large no. of analyses and direct comparison of the acids and the derivs. described below, the identity of the parent acids from various sources is definitely established and the above compn. assigned in preference to the alternative  $C_{20}H_{30}O_4$ . Mol. refractivity data support this conclusion. The systematic nomenclature used is suggested by R. and H. to replace the various names occurring in the earlier literature. By the Ag salt method I yields a *di-Me ester*,  $b_{0.1} 196-8^\circ$ ,  $[\alpha]_D^{25} 61.2^\circ$  to  $54.6^\circ$  in EtOH,  $d_4^{25} 1.076$ ,  $n_D^{25} 1.5178$ . Catalytic reduction of I yields the *tetrahydro deriv.*, purified through its *di-Me ester*,  $b_{0.1} 189-90^\circ$ ,  $b_{0.1} 165-6^\circ$ ,  $[\alpha]_D^{25} 47.9^\circ$  to  $42.4^\circ$  in EtOH,  $d_4^{25} 1.040$ ,  $n_D^{25} 1.4910$ . Heating I above its m. p. gives *noragathic acid*,  $C_{19}H_{28}O_4$ ,  $b_{0.1} 195-7^\circ$ ,  $b_{0.1} 180-3^\circ$ , m.  $146.7^\circ$ ,  $[\alpha]_D^{25} 59.3^\circ$  (1.81% soln. in EtOH); *Me ester*,  $b_{0.1} 151-2^\circ$ ,  $d_4^{25} 1.002$ ,  $n_D^{25} 1.5087$ ,  $[\alpha]_D^{25} 57.02^\circ$  (4.5% soln. in EtOH). Catalytic reduction gives *tetrahydronoragathic acid*, m.  $133^\circ$   $[\alpha]_D^{25}$

50.3° (2.2% soln. in EtOH); *Me ester*,  $b_{0.5}$  141-2°, m. 52-3°,  $d_4^{25}$  0.9411,  $n_D^{25}$  1.4693. I thus contains 2 double bonds, which, unlike those in abietic acid, exhibit no difference in reactivity and the mol. refractivity data are in good agreement with the dicyclic structure thus required. Catalytic dehydrogenation of the amorphous, Et<sub>2</sub>O-sol. resin acids from kauri copal with Se yields the C<sub>10</sub>H<sub>8</sub>MeEt obtained similarly from soft Manila copal, a hydrocarbon, C<sub>17</sub>H<sub>20</sub> (*picrate*, m. 138°), and some retene, but no pimarthere. Dehydrogenation of pure I yields the same hydrocarbon, C<sub>17</sub>H<sub>20</sub>, and pimarthere but no retene.

C. J. WEST

**Conjugated double bonds. IX.** The coloring matter in *physalis alkekengi* and *physalis franchetti*. RICHARD KUHN AND WILLY WIEGAND. *Helv. Chim. Acta* 12, 499-506(1929).—The pigment *physaliene* was isolated from both *Physalis alkekengi* and *Physalis franchetti*. It is present in the sepals to the extent of 0.9 to 1.8% and also in the skin of the berries to the extent of 0.05% based on the dry fruit. Its chem. and phys. properties make it akin to the carotene class of hydrocarbons although its formula, C<sub>60</sub>H<sub>80</sub>O<sub>4</sub>, contains O. Upon hydrogenation in the presence of PtO the pigment absorbs 11 to 11.6 mols. of H<sub>2</sub> to yield the colorless, optically inactive, cryst. compd., *perhydrophysaliene*. Oxidation leads to the formation of 5 mols. of HOAc. These facts indicate that the mol. of physaliene contains 11 double bonds and 5 Me groups. The parent hydrocarbon can thus be considered as a polymer of isoprene contg. 12 C<sub>4</sub>H<sub>6</sub> particles. Physaliene m. 97° to an orange-red liquid which at 200° fades in color and a colorless oil distills over. The distillate soon solidifies. Xylene is not a product of the thermal decompn. In air the pigment undergoes autooxidation and absorbs 3.9% of its wt. of dry O<sub>2</sub> at atm. pressure in 36 hrs. It reacts with I to give the dark green compd., *physaliene diiodide*, C<sub>60</sub>H<sub>80</sub>I<sub>2</sub>O<sub>4</sub> (0.16 g. from 0.22 g. of physaliene and 0.064 g. of I). The spectrum exhibits 3 bands whose position varies with the solvent. In CS<sub>2</sub> the optical centers are at the points 5145, 4814 and 4498 Å. U.; in petroleum ether they are displaced to the points 4830, 4515, 4230 Å. U. The first 2 bands are much more intense than the 3rd, the ratio of the intensities being 8:10:1. I. M. L.

**Action of chloro derivatives (metallic and non-metallic chlorides) on cholesterol.** VII. E. MONTIGNIE. *Bull. soc. chim.* 45, 302-4(1929); cf. C. A. 23, 2446.—Cholesterol was treated with ICl<sub>3</sub>, S<sub>2</sub>Cl<sub>2</sub>, PCl<sub>5</sub>, As<sub>2</sub>O<sub>3</sub> in HCl, SbCl<sub>3</sub>, CaCl<sub>2</sub> and SnCl<sub>4</sub>. PCl<sub>5</sub> produces the chloride, C<sub>27</sub>H<sub>46</sub>Cl; CaCl<sub>2</sub> reacts as it does with other alcs.; As<sub>2</sub>O<sub>3</sub> in HCl and SbCl<sub>3</sub> produce a red and violet color, resp.; from the others indefinite solids were obtained.

I. M. LEVINE

**Sterol group. III. Acetylation and catalytic hydrogenation of ergosterol.** ISIDOR M. HEILBRON AND WILFRED A. SEXTON. *J. Chem. Soc.* 1929, 921-6; cf. C. A. 22, 1980.—Catalytic reduction of ergosterol (I) in Et<sub>2</sub>O or EtOH gives  $\alpha$ -ergosterol (II), m. 130-1°. Catalytic reduction of 5 g. I (350 cc. H) gives dihydroergosterol, identical with that obtained by Windaus and Brücken by reduction of I with Na and EtOH, and some II. Reduction of I in glacial AcOH at 70° (8 hrs.) gives *allo*- $\alpha$ -ergosterol acetate, identical with that obtained by Reindel and Walter by hydrogenation of  $\beta$ -ergosterol acetate. I, AcOK and AcOH, heated at 100° for 5-6 hrs. in a stream of CO<sub>2</sub>, give *ergosterol  $\alpha$ -acetate* (III), m. 132-3°, which is considered the normal Ac deriv., heating with Ac<sub>2</sub>O 1 hr. converts it into the  $\beta$ -acetate, m. 172-4°, as does heating the molten compd. at 170-80° for 0.5 hr. Catalytic reduction of III gives  $\alpha$ -ergosterol acetate, m. 109-10°; hydrolysis of III gives I. IV. **Existence of isomeric ergosterols.** I. M. HEILBRON, W. A. SEXTON AND FRANK S. SPRING. *Ibid* 926-31.—The above work was carried out with a I from Böhringer und Söhne of Hamburg; in continuing a I from Messrs. Boot (IV) was used, which under identical conditions of reduction gave only a dihydro deriv. instead of the tetrahydro deriv. from I. The pure IV had  $[\alpha]_{D}^{25}$  -171° and the pure I -159.3°; both showed the same m. p. The extinction coeffs. were slightly different, the ratio being of the order 1.2 (I):1.0 (IV). The acetates of I and IV, although having the same m. p. and optical activity, still showed the same difference on hydrogenation. Hydrolysis of the IV acetate gives a sterol identical with I. A 2nd sample from Boot behaved like I. The m. p. of ergosterol  $\beta$ -acetate depends upon the duration of the treatment with Ac<sub>2</sub>O; the longer the treatment, the lower is the m. p. and the higher the optical activity.

Blau gas (DAL PRATO) 21. Electrosynthesis of hydrocarbons (MERMEJO, BLAS) 4. Ionone (HERNÁNDEZ, *et al.*) 17. Adrenaline as an oxidation catalyzer. Oxidative deamination of amino acids by means of adrenaline or some simple hydroxybenzenes (BLIX) 11A. A vapor-pressure chart for hydrocarbons (COATS, BROWN) 2. The theory of molecular dislocation applied to homogeneous catalysis (BÖSSKEN) 2. Activity of

various catalysts in promoting the oxidation of  $\text{CH}_4$  by means of O (CAMPBELL). 2. Scrubbing effluent gases (as in production and purification of phthalic anhydride) (U. S. pat. 1,718,028) 13. Extracting volatile substances from aqueous solutions (Austrian pat. 112,980) 13.

**KLARMANN, E.: Handbuch der biologischen Arbeitsmethoden.** Edited by Emil Aberhalden. Abt. I. Chemische Methoden. Teil 2, Hälfte 2. Heft 4 (Lieferung 204). *Darstellung metallorganischer Verbindungen.* Berlin and Vienna: Urban & Schwarzenberg. pp. 2149-2307. M. 8. Reviewed in *Chem. News* 138, 381(1929).

**Unsaturated carbon compounds.** LÁSZLÓ AUER. Swiss 130,435, Sept. 29, 1926. The phys. properties of colloids contg. unsatd. C compds are changed non-chemically by adding a small quantity of dry electrolyte and dispersing it therein by warming. The electrolyte may be an org. or inorg. salt.

**Furnace for the production of unsaturated hydrocarbons.** I. G. FARBENIND. A.-G. Fr. 653,646, May 1, 1928. In the production of olefins, etc., by heat decompn of paraffins, the hot parts of the decompn. furnace are made from alloys of metals of the Fe group among themselves or with common metals at the large min. of the curve of atomic vols. of the elements, or with alloys of the latter with other metals, or the hot parts of the furnace are made of materials which provoke abundant deposition of C and these are coated with preserving substances. Examples are given of the use of V2A steel, of Fe faced with a Cu-Mn bronze and lined with CaO and fragments of Cr, or coated with a thin layer of a paste made with KOH,  $\text{K}_2\text{SiO}_3$ , kieselguhr and water, or with NaOH, kieselguhr and sol. glass.

**Chlorinating organic compounds.** MICHAEL POLÁNYI and STEPHAN VON BOGDANDY. Fr. 653,163, Apr. 20, 1928. Org. compds., particularly hydrocarbons, are chlorinated by adding to a gaseous mixt. of the org. compd and Cl a small amt of a "primer" in vapor form which will not react with the org. compd. but will react readily with the Cl. Thus, Na, Cd or Zn vapor is added to a mixt. of  $\text{CH}_4$  and Cl to form  $\text{CH}_3\text{Cl}$ , it being assumed that the reaction is due to liberation of atomic Cl.

**Chlorination of hydrocarbons.** EUGENE E. AYRES, JR. (to B. A. S. Co.). U. S. 1,717,136, June 11. In the chlorination of pentanes or other hydrocarbons that exist in vapor phase at temps at which their rate of reaction with Cl is low, Cl is introduced into the hydrocarbon vapor while maintaining the latter in motion at a velocity in excess of one-half that required for distinct turbulent flow of the mixt.

**Organic arseno compounds.** SCHERING-KAHLRAUM A.-G. (Arthur Binz and Curt Rath, inventors). Ger. 475,937, July 23, 1925.  $\text{AsH}_3$  derivs. of the general formula  $\text{RAS}_2\text{H}_2$  are allowed to react with oxy or halogen derivs. of the general formula  $\text{RASO}$  or  $\text{RAS}(\text{halogen})_2$  in the presence of a small amt. of reducing agent such as hypophosphite, R denoting an aliphatic, aromatic, or heterocyclic residue. Thus, *p*-aminophenylarsenic acid is reduced with Zn and HCl to form the arsine deriv., which is filtered off and stirred into 2-hydroxypyridine-5-dichloroarsine.  $\text{NaH}_2\text{PO}_2$  is added and after stirring for about an hour and filtering, 2-hydroxy-4'-amino-5,1'-arsenopyridinebenzene is obtained. Other examples are given.

**Liquid hydrocarbons from acetylene.** FERDINAND GROS. Ger. 475,883, Jan. 22, 1924. Liquid hydrocarbons are obtained from  $\text{C}_2\text{H}_2$  by pyrogenetic conversion in a tube or vessel heated electrically. In the example, a mixt. of 50%  $\text{C}_2\text{H}_2$  and 50% H is heated to  $580^\circ$  and the product cooled giving a mixt. of liquid hydrocarbons which are fractionated to give benzene 38.1, toluene 2.6 and naphthalene 7.5%.

**Dehydration of organic salts.** SAMUEL KAN. Fr. 653,388, April 25, 1928. Org. salts contg. water of crystn. are dehydrated in an autoclave with steam at a temp. above  $120^\circ$ .

**Protection of organic compounds against lower organisms.** I. G. FARBENIND. A.-G. (Karl Dobmaier, inventor). Ger. 475,703, Oct. 24, 1926. The org. compds. prepd. according to 442,125, 442,840 and 456,979 (acids, alcs., aldehydes and ketones), particularly the high-boiling constituents, are protected from vegetable and animal organisms by admixture of Turkey red oil, with or without soap.

**Esters.** CONSORTIUM FÜR ELEKTROCHEMISCHE INDUSTRIE, G. M. B. H. Fr. 653,705, May 2, 1928. Esters are prepd. by treating vinyl esters with uni- or multi-valent alcs. or with phenols with or without a catalyst. Examples are given. Mixed esters may also be produced.

**Esters.** I. G. FARBENIND. A.-G. Fr. 654,535, May 22, 1928. Esters are prepd. from org. acids and alcs. in the presence of small quantities of metallic soaps or oxides.

In examples (1) the fatty acid of peanut oil and glycerol are heated with the addn. of 0.1% of the stannous salt of the fatty acid, (2) the fatty acid of olive oil is heated with glycerol in the presence of 0.2% of Mg oleate. Both esters may be employed as foods.

**Ketonic esters.** ALEXANDER WACKER GESELLSCHAFT FÜR ELEKTROCHEMISCHE IND., G. M. B. H. Fr. 654,413, May 18, 1928. Esters of ketonic acids are prepd. by treating carboxylic esters of BuOH or higher alcs. with metal alcoholates. Examples are given.

**Polysulfide ester of aromatic acids.** ROBERT EDER. Swiss 131,284, to 131,290, May 27, 1927. Addns. to 129,730. Mercapto-benzoic or -salicylic acid, an ethylating agent and a S halide are allowed to interact. Thus, 2-mercaptobenzoic acid is dissolved in methylene chloride with  $\text{SCl}_2$  and warmed. The filtered residue is shaken with acetone, boiled with alc. and dried to give dibenzoic acid-2,2'-trisulfide as a yellow powder m. 302-304°. The sulfides are used in therapy. Cf. C. A. 23, 1137.

**Esters and alcohols.** E. I. DU PONT DE NEMOURS AND CO. Fr. 652,845, Mar. 17, 1928. Vapors of alcs. contg. more than one C atom are passed over a heated dehydrogenating catalyst under pressure whereby the yield of the corresponding ester is increased, and an alc. with twice the no. of C atoms is formed, whereas the production of aldehyde and acid is diminished. An example is given of the passage over a catalyst of EtOH at 350° under 270 atm. giving AcOEt, *n*-BuOH and a small quantity of AcH. Catalysts used are metals such as Cu, Ni, Co and Fe to which oxides of other metals such as Mn, Cr, Mg, Ca or Zn may be added.

**Separating alcohols from mixtures.** IRLING H. HAABESTAD (to B. A. S. Co.) U. S. 1,716,957, June 11. Monohydric alcs. which are somewhat sol. in water and contain 4 to 6 C atoms are sepd. from mixts. also contg. a volatile substance such as  $\text{AmCl}$ ,  $\text{BuCl}$  or hydrocarbon material which is substantially insol. in water, by treating the mixt. with water to form a soln. of the desired alc., heating the soln. to distil water and the alc. together, condensing the vapors, sepg. the alc. from the condensate, and returning the residues of the heating and sepg. operations to the previous treatment stage. An arrangement of app. is described.

**Metal alcoholates.** ALEXANDER WACKER GESELLSCHAFT FÜR ELEKTROCHEMISCHE INDUSTRIE G. M. B. H. Fr. 653,818, May 3, 1928. Metallic compds. of alcs. having more than 3 C atoms are obtained by distg. the alcs. with the metal hydroxides until the formation of alcoholate is complete. Examples are given.

**Aromatic hydroxy compounds.** I. G. FARBENIND. A.-G. (Hermann Schütte, inventor). Ger. 475,827, Sept. 7, 1926. Sulfurized condensation products of aromatic hydroxy compds. sol. in water are prepd. by treating PhOH or its derivs. or homologues, with HCHO, sulfites and S, in presence of alkali. Examples mention PhOH, *m*-cresol and *p*-chlorophenol as the starting substances.

**Hydroxyaldehydes.** I. G. FARBENIND. A.-G. Fr. 653,975, May 8, 1928. Aromatic hydroxyaldehydes, e. g. salicylaldehyde, vanillin and 5-formyl-1,2,3-*o*-cresotic acid are prepd. by treating hydroxyalkylamines with isatin or its derivs. in the presence or absence of an oxidizing gas.

**Unsaturated aldehydes.** ANGELO KNORR and ALBERT WEISENBORN (to Wintthrop Chemical Co.). U. S. 1,716,822, June 11. An aldehyde which has no  $\text{CH}_2$  group in the 2-position to the formyl group is condensed with an aldehyde which contains a  $\text{CH}_2$  group in the 2-position to the formyl group, in the presence of an alk. agent such as KOH and an org. solvent such as EtOH contg. less than half its wt. of water. The diminution of the proportion of water present in such reactions counteracts the formation of aldols. Examples are given of the formation of:  $\text{PhCH}(\text{CMe}_2)\text{CHO}$ ;  $\text{PhCH}:\text{C}(\text{CHMe}_2)\text{CHO}$ ,  $b_{13}$  132-4°;  $\text{PhCH}:\text{C}(\text{CHMe}_2)\text{CHO}$ ,  $b_{13}$  133-5°; *p*-MeO- $\text{C}_6\text{H}_4\text{CH}:\text{C}(\text{Et})\text{CHO}$ ,  $b_{13}$  169-72°; *p*-MeOC<sub>6</sub>H<sub>4</sub>CH: $\text{C}(\text{Am})\text{CHO}$ ,  $b_{13}$  195-200°; Me-(CH<sub>2</sub>)<sub>3</sub>CH $\text{EtCH}:\text{C}(\text{Am})\text{CHO}$ ,  $b_{10}$  150-5°; MeCH<sub>2</sub>CH<sub>2</sub>CH: $\text{C}(\text{EtCH}:\text{C}(\text{Am})\text{CHO})$ ,  $b_{10}$  150-5°;  $\text{PhCH}:\text{CHCH}:\text{C}(\text{Et})\text{CHO}$ ,  $b_{12}$  172-80°;  $\text{PhCH}:\text{CHCH}:\text{C}(\text{MeCHO})$ ,  $b_{18}$  170-80°; m. 58°, pale yellow crystals;  $\text{PhCH}:\text{CHCH}:\text{C}(\text{AmCHO})$ ,  $b_{18}$  203-10°, yellow liquid;  $\text{PhCH}:\text{C}(\text{MeCH}:\text{C}(\text{MeCHO}))$ , m. 43°,  $b_{14}$  175-80°, pale yellow crystals;  $\text{PhCH}:\text{C}(\text{MeCH}:\text{C}(\text{EtCHO}))$ ,  $b_{18}$  185-90°.

**Aroylating agents.** BRITISH DYE STUFFS CORP., LTD. Fr. 653,030, April 19, 1928. See Brit. 293,924, C. A. 23, 1650.

**Methylsulfinic acid salts of secondary aromatic-aliphatic amines.** I. G. FARBENIND. A.-G. (Max Bockmühl and Kurt Windisch, inventors). Ger. 467,627, Mar. 5, 1921. The amines are condensed with formaldehydesulfoxylate. In the examples, (1) the Na salt of 1-phenyl-2,3-dimethyl-5-pyrazolone-4-methylaminomethylsulfinic acid is obtained from 4-monomethylaminoantipyrine; (2) the Na salt of *N*-ethyl-*p*-phenetidinomethylsulfinic acid is obtained from *N*-ethyl-*p*-phenetidine; (3) the Na

salt of *N*-methyl-*p*-phenetidinemethylsulfinic acid is obtained from *N*-methyl-*p*-phenetidine.

***N*-Methyl sulfités and *N*-methanesulfinic acid salts of secondary aromatic aliphatic amines.** I. G. FARBENIND. A.-G. (Max Bockmühl and Kurt Windisch, inventors). Ger. 476,643, Mar. 5, 1921. Addn. to 421,505. The *N*-methyl sulfité or *N*-methanesulfinic acid salt obtained by the condensation of primary aromatic amines with  $\text{CH}_2\text{O}$  and  $\text{NaHSO}_3$  or with formaldehydesulfoxyate, after the manner of the prior patent (cf. C. A. 16, 3732, U. S. 1,426,348), is treated with alkylating agent. Thus, Na 1-phenyl-2,3-dimethyl-5-pyrazolone-4-ethylaminomethyl sulfite is prepd. by shaking the aminomethyl sulfite soln. with  $\text{Na}_2\text{CO}_3$  and  $(\text{Et})_2\text{SO}_4$ . The substance m.  $80-90^\circ$ . Other examples are given.

**Benzanthrone derivatives.** I. G. FARBENIND. A.-G. Fr. 652,920, April 16, 1928. Benzanthrone derivs. are prepd. by treating with a metallic chloride alone, or a metallic chloride and an oxidizing agent, either 4-benzoyl-1,8-naphthalic anhydride or its derivs. or substitution products, or the reaction products of 4-royl-1,8-naphthalic anhydride or its derivs. and  $\text{NH}_3$  or an aromatic monoamine or *o*-diamine, in both cases in the presence or absence of a flux or diluent. Examples, benzanthrone-*peri*-dicarboxylic anhydride, m. above  $300^\circ$ ; 7-chlorobenzanthrone-*peri*-dicarboxylic anhydride, m. above  $300^\circ$ ; the *N*-phenylimide of benzanthrone-*peri*-dicarboxylic acid, m. above  $300^\circ$ ; a dye which dyes cotton orange-red from the vat from 4-benzoyl-1,8-naphthoylenebenzimidazole (by condensation of 4-benzoyl-1,8-naphthalic anhydride with *o*-phenylenediamine); a dye giving brown shades on cotton from the vat from 4-benzoyl-1,8-naphthoylene(1,2-naphthylene)imidazole (by condensation of 4-benzoyl-1,8-naphthalic anhydride with 1,2-naphthylenediamine).

**Diarylguanidines.** ALFRED E. PARMELEE (to E. I. Du Pont de Nemours & Co.). U. S. 1,716,081, June 4. In sepg. and purifying di-*o*-tolylguanidine or other diarylguanidine produced by desulfurizing a diarylthiourea, any excess of  $\text{NH}_3$  and alc. present in the reaction mass is removed, the remaining mixt. is acidified with an acid such as  $\text{HCl}$  which will dissolve impurities present, and there is added to the resulting soln. a sufficient quantity of an alk. reacting substance such as  $\text{Na}_2\text{CO}_3$  to ppt. the impurities while leaving the diarylguanidine in soln.

**Butadienes.** I. G. FARBENIND. A.-G. Fr. 653,600, April 30, 1928. Butadienes are produced by heating a mixt. of 1 vol. of steam and 2 vols. of a formenic, ethylenic, cycloane or cycloene hydrocarbon (not a monocyclic terpene) to a high temp. in the presence of a catalyst or not, and at ordinary or reduced pressure. In an example a mixt. of hexamethylene (2 vols.) and steam (1 vol.) is passed over large grains of  $\text{CaO}$  at  $680^\circ$ , giving butadiene, butylene, propylene, etc. The catalysts described in Fr. 635,889 as well as silicates,  $\text{SiO}_2$ , precious metals, Cr, V, Mn, Co or their alloys or alloys of Fe contg. Cr, Ni, V, Mn, Co, Mo or W may be used. Cf. C. A. 23, 1143.

**Xanthates.** JOSEPH H. JAMES (to Clarence P. Byrnes, trustee). U. S. 1,716,273, June 4. Xanthate mixts. suitable for use in flotation processes or in prepg. insecticides or fungicides are obtained by the reaction of  $\text{CS}_2$  and alkali hydroxide on mixts. produced by the catalytic oxidation of kerosene, gas oil or similar products.

**Diazo preparations.** I. G. FARBENIND. A.-G. Fr. 33,946, July 29, 1927. Addn. to 610,261. Prepns. of stable diazo salts are made by adding as stabilizer a free aryl-sulfonic acid, alone or mixed with an easily sol. salt.

**Carbazole derivatives.** I. G. FARBENIND. A.-G. Fr. 654,129, May 12, 1928. Carbazole derivs. are prepd. by introducing groups into carbazoles substituted with easily removable groups which are then removed. In examples, 1-aminocarbazole-3,6,8-trisulfonic acid is prepd. by nitrating carbazole-3,6,8-trisulfonic acid and reducing, the  $\text{SO}_3\text{H}$  groups are then eliminated by heating under pressure with dil.  $\text{H}_2\text{SO}_4$ . Similarly 1,8-dihydroxycarbazole is prepd. from 1,8-dihydroxycarbazole-3,6-disulfonic acid.

**1-Aminocarbazole and derivatives.** I. G. FARBENIND. A.-G. Fr. 654,074, May 10, 1928. The above are prepd. by exchanging the OH group of 1-hydroxycarbazole or its derivs. by an  $\text{NH}_2$  group in known manner such as by heating under pressure with  $(\text{NH}_4)\text{HSO}_4$ .

***N*-Dihydro-1,2,1',2'-anthraquinoneazaine and derivatives.** I. G. FARBENIND. A.-G. Fr. 654,686, Oct. 6, 1927. The above are prepd. by fusing 2-aminoanthraquinone or its derivs. with caustic alkali with addn. of salts of lower fatty acids as well as salts of higher fatty acids or alcoholates or phenolates. *N*-Dihydro-1,2,1',2'-anthraquinoneazaine is chlorinated by passing in  $\text{Cl}$  in the presence of  $\text{H}_2\text{SO}_4$  of 85-95% strength and at a temp. of  $40-70^\circ$ . The dichloro compd., is particularly valuable as a dye, it may be reduced to the hydrazine compd. by reducing agents.

**Mercaptans of the furfuryl series.** HERMANN STAUDINGER and THADEUS REICH-

STEIN (to Internationale Nahrungs-und Genussmittel A.-G.). U. S. 1,715,795, June 4. See Can. 283,765 (C. A. 22, 4537).

**Quaternary ammonium compound.** SOC. ANON. POUR L'IND. CHIM. A BALE. Swiss 130,881, July 26, 1927. See Brit. 294,582 (C. A. 23, 1909).

**Concentrating volatile aliphatic acids.** HOLZVERKOHLEUNGS-INDUSTRIE A.-G. Fr. 652,965, April 17, 1928. See Can. 285,930 (C. A. 23, 1141).

**Concentrating volatile aliphatic acids.** HOLZVERKOHLEUNGS-INDUSTRIE A.-G. Fr. 652,966, April 17, 1928. See Can. 285,929 (C. A. 23, 1141).

**Concentrating volatile aliphatic acids.** HOLZVERKOHLEUNGS-INDUSTRIE A.-G. Fr. 652,967, April 17, 1928. See Can. 285,928 (C. A. 23, 1141).

**Sulfonic acids.** I. G. FARBENIND. A.-G. Fr. 654,080, May 11, 1928. True sulfonic acids are prepd. from unsatd. aliphatic or hydroaromatic hydrocarbons or their derivs. by treating these compds. with sulfonating agents in the presence of substances capable of forming with sulfonating agents onium (oxonium, ammonium, thionium, etc.) compds. or by esters of  $\text{ClHSO}_3$  or substances capable of forming them. Examples are given.

**Sulfonic acids.** ORANIENBURGER CHEMISCHE FABRIK A.-G. Fr. 653,790. May 2, 1928. See Brit. 289,841 (C. A. 23, 848).

**Aromatic sulfonic acids.** I. G. FARBENIND. A.-G. (Karl Dachlauer and Emil Thiel, inventors). Ger. 476,906, June 3, 1925. Aromatic sulfonic acids are prepd. by treating a mixt. of aromatic hydrocarbon and  $\text{EtOH}$  or  $\text{MeOH}$  with  $\text{ClHSO}_3$  or fuming- $\text{H}_2\text{SO}_4$  at high temps. (110–130°). Cf. C. A. 23, 848.

**Sulfonic acids of *N*-acetylacetic arylamides.** I. G. FARBENIND. A.-G. Fr. 653,210, Dec. 3, 1927. The above are prepd. by sulfonating *N*-acetylacetic arylamines in the absence of water and with sulfonating agents not contg. water such as oleum contg. 10–20%  $\text{SO}_3$  and at a low temp. The products can be coupled with diazotized  $\text{PhNH}_2$  for the production of dyes.

**Sulfonic acids of 6-chloro-2-amino-1-toluene.** I. G. FARBENIND. A.-G. Fr. 653,878, May 4, 1928. See Brit. 290,229 (C. A. 23, 849).

**1-Aminoanthraquinone-2-sulfonic acid.** I. G. FARBENIND. A.-G. Fr. 653,159, April 20, 1928. See Brit. 289,097 (C. A. 23, 609).

**$\beta$ -Naphthol-1-sulfonic acid.** ALFRED E. PARMELEE (to E. I. duPont de Nemours & Co.). U. S. 1,716,082, June 4.  $\beta$ -Naphthol, suspended in *o*-nitrotoluene, is sulfonated with chlorosulfonic acid at a temp. below 10°. Cf. C. A. 22, 1365.

**Maleic acid.** THE BARRETT COMPANY. Ger. 475,808, April 27, 1921. Maleic acid is formed by exposing vaporized aromatic hydrocarbons contg. one or more benzene rings and a side chain to  $\text{V}_2\text{O}_5$  with air or  $\text{O}$  at 400–550°. Thus, toluene and air exposed to  $\text{V}_2\text{O}_5$  for 16 hrs. at 410° yield benzoic acid, maleic acid and benzaldehyde.

**Acetic anhydride.** CONSORTIUM FÜR ELEKTROCHEMISCHE IND., G. M. B. H. (Rudolf Meingast and Martin Mugdan, inventors). Ger. 475,885, Oct. 19, 1926. See Fr. 643,114 (C. A. 23, 1419). Acetic anhydride is prepd. by heating  $\text{AcOH}$  vapor to high temps. with a small quantity of gaseous catalyzer, preferably a weak inorg. acid. In the examples,  $\text{H}_3\text{PO}_4$ ,  $\text{H}_3\text{BO}_3$ ,  $\text{NaPO}_3$  and  $\text{Et}_3\text{PO}$  are mentioned as the catalyzers.

**Acetic anhydride.** I. G. FARBENIND. A.-G. Fr. 652,820, Feb. 10, 1928.  $\text{Ac}_2\text{O}$  produced by heat decompn. of  $\text{AcOH}$  is freed from water by passing the mixt. of vapors still superheated into a fractionating column down which streams an indifferent solvent such as  $\text{C}_6\text{H}_6$ , toluene,  $\text{CHCl}_3$ ,  $\text{C}_2\text{H}_4\text{Cl}_2$ ,  $\text{C}_2\text{HCl}_3$ , etc., or a mixt. such as  $\text{C}_6\text{H}_6$  and  $\text{C}_2\text{H}_5\text{Cl}$  or  $\text{C}_6\text{H}_6$  and quinoline. The water may also be removed by surmounting a dephlegmator on the fractionating column, and injecting a mixt. such as  $\text{C}_6\text{H}_6$  and  $\text{C}_2\text{HCl}_3$  at the base, without forming a stream in the column.

**Methanol.** I. G. FARBENIND. A.-G. Fr. 652,898, April 16, 1928.  $\text{MeOH}$  is produced from  $\text{CO}$  and  $\text{H}$  at 100–250° using catalysts having a basis of particularly active  $\text{Cu}$ . The  $\text{Cu}$  may contain oxides of metals from the 2nd to the 7th group of the periodic system, pptd. from aq. solns. of salts of the metals. In an example a mixt. of  $\text{CuO}$  and  $\text{MgO}$  obtained by pptn. at 20° of 2 mols. of  $\text{Cu}(\text{NO}_3)_2$  and 1 mol. of  $\text{Mg}(\text{NO}_3)_2$  by dil. aq.  $\text{NaOH}$ , with washing and drying up to 250°, is reduced for 30 hrs. by a mixt. of  $\text{N}$  and  $\text{H}$  contg. 5% of  $\text{H}$  at 100–250°. If a mixt. of  $\text{CO}$  and  $\text{H}$  contg. 33%  $\text{H}$  is directed on to this catalyst at 150° a good yield of  $\text{MeOH}$  is obtained contg. only traces of compds. reacting with  $\text{Br}$ .

**Methanol synthesis.** HENRY DREYFUS. Fr. 653,554, April 28, 1928. Catalysts for the synthesis of  $\text{MeOH}$  are prepd. by pptg.  $\text{ZnCO}_3$  in a gelatinous form, washing by decantation and drying the product under reduced pressure so as to retain the colloidal state, and heating the gel to a temp. not above that to be used in the synthesis, e. g., 400°. The  $\text{ZnCO}_3$  gel may be produced by pptn. in a very dil. soln., or by incorporating

during or after pptn. with a protective colloid such as starch, pectin, saponin or hydrated  $\text{SiO}_2$ . The catalyst may be used in conjunction with a promoter such as 5-10% of  $\text{Cr}_2\text{O}_3$  or other catalyst.

**Aldol.** I. G. FARBERIND. A.-G. Fr. 654,315, May 15, 1928. See Brit. 298,349 (C. A. 23, 2725).

**Borneol.** GÁZA AUSTERWEIL. Fr. 654,550, May 22, 1928. Borneol is prepd. by heating nopinene with org. acid anhydrides, *e. g.*, phthalic anhydride, with the addn. of alc. drop by drop, so that a reaction takes place between nopinene and an acid in the nascent state, giving a bornyl ether, which is afterwards sapond., the alc. and anhydride being reformed in known manner.

**$\alpha$ -Naphthol.** ALEX B. DAVIS (to Pennsylvania Coal Products Co.). U. S. 1,717,009, June 11. In order to obtain pure  $\alpha$ -naphthol from naphthol contg. both  $\alpha$ - and  $\beta$ -naphthol, the naphthol is subjected to the action of an alk. earth substance such as  $\text{Ca}(\text{OH})_2$  which forms with the  $\alpha$ -component a relatively sol. and with the  $\beta$ -component a relatively insol. product and these products are sepd. by their different solys.

**Hexylresorcinol.** HERMANN HIRZEL (to Sharp & Dohme). U. S. 1,717,105, June 11. Resorcinol is caused to react with a hexyl halide, *e. g.*, with hexyl chloride in the presence of Zn or Cu.

**Heptylresorcinols.** ALFRED R. L. DOHME (to Sharp & Dohme). U. S. 1,717,098, June 11. Heptylresorcinols in a purified state are subjected to reduction with Zn amalgam and HCl.

**Formaldehyde.** I. G. FARBERIND. A.-G. Fr. 33,810, June 30, 1927. Addn. to 617,032. In the production of  $\text{CH}_2\text{O}$  by the catalytic oxidation of MeOH, the gases from the reaction contg.  $\text{CH}_2\text{O}$  and water vapor are cooled and washed with very concd. solns. of  $\text{CH}_2\text{O}$ . Cf. C. A. 23, 1650.

***m*- and *o*-Hydroxybenzaldehydes.** FREDERICK H. KRANZ (to National Aniline & Chemical Co.). U. S. 1,715,417, June 4. A crude nitrated benzaldehyde is reduced, the amino compds. thus obtained are diazotized, the diazo product is distd. in the presence of water, and the *m*-hydroxybenzaldehyde is recovered from the residue in the distg. app. and the *o*-hydroxybenzaldehyde from the distillate.

**Diiodotrimethylamine.** LÉON GROUCHKINE. Fr. 652,809, Dec. 16, 1927. See Australia 11,019.

**Tetrahydro-*N*-ethyl- $\beta$ -naphthylamine.** SOC. ANON POUR L'IND. CHIM. À BAËLE. SWISS 130,836, April 8, 1927. Addn. to 130,423 (C. A. 23, 2987). This substance is prepd. by the catalytic hydrogenation of *N*-ethyl- $\beta$ -naphthylamine. Ni is mentioned as the catalyzer.

**2-Aminopyridine.** DEUTSCHE GOLD- UND SILBER-SCHNEIDANSTALT VORM. ROESLER. (Karl Vieweg, inventor). Ger. 476,458, Dec. 17, 1925. 2-Aminopyridine is prepd. by heating equimol. amts. of pyridine and an alkali amide in an indifferent medium such as toluene to a temp. below the b. p. of pyridine, preferably below 100°.

**Dibenzanthrone.** I. G. FARBERIND. A.-G. Fr. 653,027, April 19, 1928. Dibenzanthrone is produced by the alk. fusion of benzanthrone in the presence of aldehydes or their derivs. or compds. which behave like aldehydes. Examples are given of the use of paraformaldehyde, Na formaldehyde bisulfite, Na formaldehydesulfoxylate, the amt. being about 15-20% of the wt. of benzanthrone. Na glyoxal bisulfite, Na benzaldehyde bisulfite or the corresponding Zn compds. may be used.

**Pentaerythritol.** CHARLES E. BURKE (to E. I. du Pont de Nemours & Co.). U. S. 1,716,110, June 4.  $\text{CH}_2\text{O}$  and acetaldehyde are condensed in aq. soln. in the presence of  $\text{Ca}(\text{OH})_2$ , the Ca is pptd. (suitably by  $\text{K}_2\text{CO}_3$  or  $\text{Na}_2\text{CO}_3$ ) and the pentaerythritol is crystd. from alk. soln.

**$\beta$ -Aminoethylurea.** J. D. RIEDEL-E. DE HÄEN A.-G. Ger. 476,533, Aug. 16, 1925. Ethylenediamine is treated with 1 mol. of an acid and 1 mol. of an alkali cyanate to produce  $\beta$ -aminoethylurea. HCl and CNOK are given in the example; the m. p. of the hydrochloride is 139-140°.

**Vanillin.** I. G. FARBERIND. A.-G. (Oskar Spengler and Hugo Pfannenstiel, inventors). Ger. 475,918, July 29, 1923. Vanillin is prepd. by subjecting trichloromethylguaiacylcarbinol to a sapon. and oxidation by a soln. of a heavy metal compd. Thus, the carbinol may be heated in a reflux condenser for 12 hrs.,  $(\text{AcO})_2\text{Cu}$  added and the mixt. heated for a further 12 hrs. The soln. is then evapd. to about half its vol. and the vanillin extd. with ether. Other examples are given.

**Styrene.** THE NAUGATUCK CHEM. CO. Ger. 476,270, Aug. 29, 1924. In the manuf. of styrene and its homologs by passing alkylated aromatic hydrocarbons, with at least 8 atoms of C and 10 of H, through a tube heated to 450-700°, the conditions are adjusted so that the amt. (R) of hydrocarbon vapor passing through the tube,

(expressed in g. per min.), the temp. (T) in the middle of the tube, and the volume (V) of the heated part of the tube (expressed in cc.), are related in accordance with the formula  $0.064V/R + T = 633K$ , where K is 0.8-1.2.

Crotyl bromide. I. G. FARBENIND. A.-G. Fr. 653,338, April 23, 1928. See Brit. 289,777 (C. A. 23, 851).

Ethylene chloride. ALBERT MAIER. Fr. 653,434, April 25, 1928.  $C_2H_4Cl_2$  is made by bringing together  $C_2H_4$  and  $Cl_2$ , both previously cooled to a low temp., c. g.,  $-30^\circ$ .

Glass atomizers for ethyl chloride. FRITZ ECKERT. Ger. 476,993, Mar. 19, 1926. Constructional details are given.

Aluminum ethylate. I. G. FARBENIND. A.-G. (Hans Meerwein, inventor). Ger. 475,557, Jan. 4, 1925. Alc.-free  $(EtO)_3Al$  is prepd. from Al and abs. alc. in the presence of a catalyzer by adding the alc. gradually by dropping into an excess of Al. The Al may be suspended in molten  $(EtO)_3Al$  or an indifferent solvent. The catalyzer may be contained in the alc.

Condensation products of the benzanthrone series. I. G. FARBENIND. A.-G. (Georg Kalischer, Heinz Scheyer, Paul Nawiasky and Emil Krauch, inventors). Ger. 475,574, Dec. 3, 1926. Addn. to 465,506. Condensation products of *Bz*-1 nitro-2-methylbenzanthrone are obtained by subjecting it to the action of other acid materials than the fuming  $H_2SO_4$  mentioned in the prior patent. An example mentions a mixt. of 100 parts fuming  $H_2SO_4$  and 50 parts chlorosulfonic acid.

Naphthalene condensation products. I. G. FARBENIND. A.-G. Fr. 33,807, June 28, 1927. Addn. to 628,440. Condensation products are prepd. by treating  $C_{10}H_8$  or its derivs. with crude or purified gases contg. olefins under pressure and in the presence of catalysts such as  $AlCl_3$ .

## 11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

### A—GENERAL

FRANK P. UNDERHILL

The substance in oysters (*Ostrae gigas* Thunberg) causing hypoglucemia. TAIZO KUMAGAI AND YOSHIO SHIKINAMI. *Tôhoku J. Exptl. Med.* 12, 425-32(1929). The hypoglucemic effect of oyster ext. is strong in summer but very weak in winter. Hepatopancreatic exts. were more active than exts. of the whole oyster; exts. from egg-cells had max. activity. Hepatopancreatic and egg exts. were similar in their hypoglucemic activity to guanidine prepsns.

B. C. BRUNSTETTER

Ultra-violet light, insulin and amino acid catalysis. JOHN M. ORT. *J. Phys. Chem.* 33, 825-41(1929); cf. C. A. 21, 1446; 22, 970.—Reduction potentials were measured in solns. of dextrose and of levulose, at  $pH = 10$ , in the presence of various amino acids, of insulin, and when exposed to ultra-violet light. Irradiation speeded up the drift in potentials before the addn. of  $H_2O_2$ , and greatly increased the speed of recovery of reducing potentials afterwards. This effect of irradiation is much greater than the catalytic effect of the amino acids previously reported; and under irradiation, the catalytic effects of the different acids are completely changed. The effect of insulin in delaying the recovery of reducing potentials was also less noticeable under irradiation.

T. H. CHILTON

Biophysical chemistry. II. V. COFMAN. *J. Chem. Education* 6, 1090-9(1929); cf. C. A. 23, 3481.

B. J. C.

Intestinal erepsin. K. LINDERSTRØM-LANG. *Z. physiol. Chem.* 182, 151-74(1929).—Ordinary erepsin prepd. from the intestinal mucosa of the hog is believed to contain 2 dipeptidases. One of these effects a max. cleavage at  $pH$  7.3 and hydrolyzes leucylglycine and glycylglycine at practically the same velocity. The other shows a  $pH$  optimum at 8.1 and hydrolyzes leucylglycine about 20 times as rapidly as glycylglycine. A detn. is rendered uncertain by the overlapping of the activity  $pH$  curves and the values should therefore be regarded as merely preliminary. The partial sepn. of the peptidases is effected by fractional extn. or adsorption on  $Al(OH)_3$ . The 1st enzyme is very unstable in aq. soln., and even in 53% glycerol it rapidly loses activity. The 2nd is much more stable and keeps well in aq. soln. at ice box temp. Whether these represent 2 separable enzymes, or 1 enzyme and 2 activators or possibly a coenzyme, is not fully established. Again, according to the modern conception of enzymes as active groups bound to colloidal carriers, 2 active groups might be bound to the same

carrier or to different carriers. The important observation is that 2 different specific actions are here manifested. Many of the proteolytic enzymes now regarded as individuals may actually be mixts., and calcs. of dissocn. consts. and enzyme affinities are at present of little significance.

**The decomposition of hemoglobin.** New chemical and bacteriological mechanistic studies. K. BRINGOLD. *Klin. Wochschr.* 8, 866-73 (1929); cf. *C. A.* 23, 178.—The blood catalase protects hemoglobin against oxidation by  $H_2O_2$ . Catalase can be destroyed *in vitro* by the action of physical (heat), chemical (acid and alkali) and bacteriological agents. The Fe in the hemoglobin mol. is also an oxidation catalyst. It is able to intensify the oxidation potential of  $H_2O_2$ . This leads to a destruction of the hemoglobin mol. by  $H_2O_2$  when the protective catalase is absent.

**Some experiments in cytology with special reference to the law of similars.** FRANK C. BENSON, JR. *Hahnemannian Monthly* 64, 321-30 (1929).—A discussion of the action of the radiations of Ra and Po in therapeutic doses and in physiol. doses. J. S. H.

**Ultra-violet absorption spectra of certain aromatic amino acids and of the serum proteins.** FRANK C. SMITH. *Proc. Roy. Soc. (London)* B104, 198-205 (1929); cf. *C. A.* 23, 1654.—In the absorption spectrum of tyrosine, new bands were found at 1940 and 2240 Å. U. The serum proteins (albumin and pseudoglobulin) of man and of the horse yielded absorption spectra that were in very close agreement. The ratio of the extinction coeff. at the head of the curve to that at the foot of the curve was an index of the purity of the protein; this ratio was: horse albumin 2.24, human albumin 2.14, pseudoglobulin (human and horse) 3.00. The ratio of albumin (A) to globulin (G) may be calcd. as follows: If the total protein be known, then  $A/G = (E_h - 1.2x) \div (5.8x - E_h)$ . If the total protein be unknown, then  $A/G = (1.5 E_g - 0.5 E_h) \div (0.325 E_h - 0.725 E_g)$ . In these formulas,  $x$  is the total concn. of protein in %,  $E_h$  extinction coeff. at the head of the absorption curve and  $E_g$  extinction coeff. at the foot of the curve. No error was introduced by scattering of the radiation by the colloidal particles of protein.

**Cytochrome and respiratory enzymes.** D. KEILIN. *Proc. Roy. Soc. (London)* B104, 206-52 (1929).—The respiratory pigment, cytochrome, is widely distributed in the cells of aerobic organisms. It is composed of 3 hematin compds. (designated  $a'$ ,  $b'$  and  $c'$ ) and an unbound hematin compd. which is similar to protohematin of hemoglobin. The components  $a'$  and  $c'$  are not autoxidizable; the component  $b'$  (in washed muscle and dried yeast cells) is autoxidizable; and the unbound hematin is autoxidizable and also (in the reduced state) combines with CO. The hemochromogen of cytochrome is autoxidizable but does not combine with CO. The hematin compds. are responsible for the thermostable peroxidase reaction with guaiac, benzidine and *p*-phenylenediamine in the presence of  $H_2O_2$ . The cells of yeast, muscle and other tissues also contain a true thermolabile insol. *indophenol oxidase*, which is greatly damaged by drying the cells in air or by treatment with acetone or alc., and is completely inactivated by a temp. of 70°. Its activity is inhibited by very small concns. of KCN and  $H_2S$ , and by CO at high partial pressure and in the dark; the inactive CO-oxidase compd. is dissoed. on exposure of the cells to light with liberation of the active enzyme. The factors which influence the oxidase also influence the  $O_2$  consumption by the cells in the same manner; hence this enzyme plays an important part in cellular respirations. The oxidation of cytochrome is inhibited or abolished by the same factors which inhibit or abolish the activity of the oxidase; hence this enzyme is responsible for the oxidation of cytochrome, especially of its components  $a'$  and  $c'$ . In the living cells, cytochrome is reduced by various org. compds. which become donors of H on activation by dehydrases; this reduction is delayed by all factors which inhibit the activity of the dehydrase system, *e. g.*, warming to 52°, very low temps. and narcotics. Cytochrome functions as a carrier between 2 types of activating mechanisms in the cell, the dehydrases which activate the H of org. mols., and the indophenol oxidase which activates  $O$ ; it acts as a H-acceptor which is specifically oxidized by the oxidase. The 3 autoxidizable hematin compds. (component  $b'$ , unbound hematin and hemochromogen of cytochrome) may also act as carriers between H-donators and mol.  $O_2$ , as well as direct catalysts in the oxidation of compds. which are not activated by sp. dehydrases. The *polyphenol* or *catechol oxidase* of potato may be obtained in a clear soln., is destroyed by a temp. of 70°, inhibited by KCN,  $H_2S$  and CO, and not injured by alc. or drying; light does not influence its inhibition by CO. A bibliography of 60 references is appended.

JOSEPH S. HEPBURN  
BRONTE

a temporary breaking down of certain lipoids supposedly located in the cortex of the Golgi app. and required for mitosis. The radiation may cause the smooth Golgi app. to become granular and flocculent. Just before prophase, recovery from the effects of broken-down lipoids is impossible, so abnormal mitosis and death of the cell occur. The centrosome is not affected by radiation.

JOSEPH S. HEPBURN

Ionic mobility as a factor in influencing the distribution of potassium in living matter. A. B. MACALLUM. *Proc. Roy. Soc. (London)* B104, 440-58(1929).—When silica sand of natural origin was used as the adsorbent, it adsorbed only K from (a) a soln. contg. KCl and NaCl in equimol. concn., and (b) a soln. contg. LiCl and KCl in approx. equimol. concn. The amt. of K adsorbed depended on the time, and on the quantity of sand through which the soln. percolated. However, when the soln. contained 0.7614% NaCl and 0.0381% KCl (the concns. in which these salts occur in human blood plasma), both K and Na were adsorbed; but the ratio of the adsorbed K to the total K of the soln. was greater than (at times more than twice) the ratio of the adsorbed Na to the total Na of the soln. These results are explained by the ionic mobility of K, which is greater than that of Na or of Li. Apparently chloride ions were not adsorbed by silica, and the soln. after percolation contained HCl, for its  $p_H$  ranged between 5.5 and 5.6 before percolation and between 3.2 and 3.8 after percolation.

J. S. H.

Protein metabolism and organic evolution. JOSEPH NEEDHAM. *Science Progress* 23, 633-48(1929).—The main nitrogenous excretory product of an animal depends upon the conditions under which its embryos live;  $NH_3$  and urea are associated with aquatic pre-natal life, and uric acid is associated with terrestrial pre-natal life. From the chemico-embryological viewpoint, mammals count as aquatic animals, since the excretion of nitrogenous waste products through the placenta is analogous to their excretion into water. The production of uric acid by the terrestrial embryo and the excretion of this insol., nondiffusible compd. into the allantoic liquid is a well-adapted mechanism which deals with incombustible waste and also permits reabsorption of water through the allantoic wall. Marine invertebrates usually excrete most of their N as  $NH_3$ . Since the alkyl. of  $NH_3$  is incompatible with even an undeveloped kidney,  $NH_3$  excretion disappears with increasing complexity of body. Neutralization by acid necessitates waste of the latter, so  $NH_3$  is replaced by urea. The chick embryo between the 2d and 5th days exhibits morphologically piscine characteristics and excretes  $NH_3$  and urea with no uric acid; evidence is thus given of its aquatic ancestry. A bibliography of 65 references is appended.

JOSEPH S. HEPBURN

Role of lipoids in the vegetative system. I. Antagonistic influence of the physico-chemical condition of lipid sols. KURT DRESEL and RICHARD STERNHEIMER. *Z. klin. Med.* 107, 739-58(1928).—Colloidal sols. contg. both cholesterol and lecithin have a different behavior than the colloidal soln. of either lipid. An antagonistic action is exerted on such mixts. of colloids by K, Cl, H and (OH). This is analogous to the physiol. antagonism of ions. Coagulation and peptization are reversible within wide limits. II. Action of colloidal lecithin and cholesterol upon the Laewen-Trendelenburg frog preparation. *Ibid* 759-84.—Colloidal lecithin acts as a vasodilator, colloidal cholesterol as a vasoconstrictor. Lecithin acts as an antagonist, cholesterol as a synergist to adrenaline. III. Action of lipid sols upon the Straub frog heart. *Ibid* 785-95.—Neither lecithin nor cholesterol produces any change in diastole or systole. Lecithin decreases and cholesterol increases the systolic action of adrenaline. Lecithin strengthens and cholesterol weakens the diastolic action of choline. IV. Influence of lipoids on the blood picture. K. DRESEL, R. STERNHEIMER and R. HIRSCH. *Ibid* 796-802.—Intravenous injection of aq. solns. of lecithin usually, though not invariably, increases the total leucocyte count and the % of lymphocytes. Administration of lecithin emulsion by duodenal tube also increases the % of lymphocytes. Administration of cholesterol intravenously or intraglutely produces no characteristic change in the blood picture. Administration of cholesterol emulsion by the duodenal tube gives rise to a relative leucocytosis. V.—Effect of adrenaline on the lecithin and cholesterol of the blood serum. K. DRESEL, R. STERNHEIMER and FRED HIMMELWEIT. *Ibid* 803-9.—Injection of adrenaline produces an increase in the cholesterol and a decrease in the lecithin of the blood serum for a short time. In paradoxical patients the injection produces first the reverse of these changes, for 10 to 20 mins., then the normal change for 30 to 50 mins., and finally a return to the normal values.

JOSEPH S. HEPBURN

Radioactive substances in a body five years after death. A. V. ST. GEORGE, A. O. GETTLER and R. H. MULLER. *Arch. Path.* 7, 397-405(1929).—The body was exhumed 5 years after interment for the purpose of obtaining evidence in connection with the death of the girl and the illness of several others who had been employed

at painting watch dials with luminous paint, the latter contg. radioactive substances. The bones and the liver, brain, lungs and spleen were tested for signs of radioactivity. Every portion of tissue and of bone tested gave photographic and electroscopic evidence of radioactivity. All 3 rays ( $\alpha$ ,  $\beta$  and  $\gamma$ ) were detected. The nature of the emanation was found to be that of Ra. Detn. (by the emanation method) showed the presence of 48,282 micrograms of Ra in the entire skeleton. The Ra content was also estd. for the lungs, liver, spleen and brain. The total estd. Ra content for entire bones, liver and lungs was 48,4179 micrograms.

HARRIET F. HOLMES

The permeability of the placenta of the rat to glycine, alanine and urea. J. M. LUCK AND E. T. ENGLE. *Am. J. Physiol.* 88, 230-6(1929).—Amino acids and urea diffused readily through the placenta of the rat into the fetus. J. F. LYMAN

Various hemoglobins and their renal thresholds in the dog. E. J. MANWELL AND G. H. WHIPPLE. Univ. of Rochester. *Am. J. Physiol.* 88, 420-31(1929).—When hemoglobin solns. were injected intravenously into normal dogs the amts tolerated before hemoglobinuria occurred was as follows: for dog blood hemoglobin 215 mg per kg. body wt., for sheep and goose hemoglobin 115 mg and for dog muscle hemoglobin 11 to 15 mg., resp. Severe prolonged anemia did not modify these threshold values. J. F. LYMAN

Glutathione. Its importance in biological oxidations and its behavior under normal and pathological conditions. V. BISCEGLIE. *Biochim. terap. sper.* 16, 134-43 (1929).—A general review with a complete bibliography. PETER MASUCCI

The variations in organic phosphorus of the blood by the action of ultra-violet rays and irradiated air. G. DE TONI AND A. STANCATI. *Boll. soc. ital. biol. sper.* 4, 165-70 (1929).—The object was to see if it was possible to obtain the transformation of labile acid-sol P into inorg. P. The normal process of hydrolysis by which the labile P in blood filtrates is transformed into inorg. P can be accelerated by direct irradiation with ultra violet rays, by bubbling atm. air through the filtrate, or by bubbling irradiated air. The latter is the most effective. PETER MASUCCI

The optimum hydrogen-ion concentration for the enzymic activity of animal asparaginase. A. CLEMENTI. *Boll. soc. ital. biol. sper.* 4, 200-2(1929).—The optimum activity of asparaginase from chicken liver is at pH 7.4-7.6. PETER MASUCCI

A contribution to the knowledge of the activity of liver amylase. I. S. VISCO AND W. DUCK. *Boll. soc. ital. biol. sper.* 4, 267-72(1929).—The glycogenolytic enzyme of dog liver does not have a true temp. optimum, but instead its action increases from 0° to 38°; then there is little fluctuation in activity until the temp. reaches 50°. Above 50°, the activity diminishes very definitely. The amylase activity of rabbit liver begins to decrease at 40°, and at 50° the quantity of glucose formed is noticeably less. Tables are given showing the amylase activity of dog and rabbit liver covering a temp. range from 0° to 100°. PETER MASUCCI

The action of scorpion poison. O. MAGALHAES. *Mem. Inst. Oswaldo Cruz* 21 [1] (1928); *Rev. sud-americana endocrinol. imunol. quimioterap.* 12, 358-9(1929).—77% of the vesicular weight is poison. It contains hemolysin, hemorrhagin, leucocytolysin, neurotoxin and agglutinin and has a proteolytic and anticoagulant action. A serum was prepd., which neutralized 50 times the lethal dose. A. E. MEYER

The chemistry of micellae and its application to biochemical and biological problems. KURT H. MEYER. *Biochem. Z.* 208, 1-31(1929).—A highly interesting discussion of the micellar structure of a variety of substances. S. MORGULIS

Physicochemical studies on irradiated proteins. VI. Further investigations on the spectroscopic and biological demonstration of the alteration of proteins by light. M. SPIEGEL-ADOLF AND Z. OSHIMA. *Biochem. Z.* 208, 32-44(1929); cf. C. A. 23, 164.—Ovalbumin in the presence of alkali to prevent any visible pptn. shows an increase in the absorption capacity in the short wave region of the spectrum, when acted upon for several hrs. by light of a Hg-vapor lamp just as was found with serum proteins. With serum albumin and pseudoglobulin the increase in absorption capacity depends upon the concn. of the added acid or alkali in that further addns. produce an equiv. rise in the absorption capacity. This, however, is only true when the acid is added before the radiation, whereas increasing the acid concn. after irradiation only increases the transmission of the ultra-violet rays. VII. Comparison of the absorption capacity in the ultra-violet by serum albumin and ovalbumin denatured through the action of heat, ultra-violet, radium and x-rays. M. SPIEGEL-ADOLF AND O. KRUMPEL. *Ibid* 45-59.—Serum and ovalbumin solns. to which acid or alkali was added to prevent coagulation and which were subjected to the action of a temp. of boiling water show an increased absorption only in the region of short wave lengths beginning with  $\lambda = 274.9 \mu\mu$ . Protraction of the time of boiling to 1 hr. does not affect the absorption

capacity of the serum albumin, but the transmission of the alk. serum albumin solns. does increase. Qualitatively the heat-denatured albumin solns. behave like solns. treated by ultra-violet radiation, but quantitatively the effect is definitely less. The influence of Ra radiation manifests itself (in alk. medium) in a much greater absorption capacity ( $\lambda = 292.6\mu\mu$ ) than is attained by heat inactivation. S. MORGULIS

The influence of protein substances on colloidal ferric hydroxide. H. FREUNDLICH AND G. LINDAU. *Biochem. Z.* 208, 91-111(1929); cf. *C. A.* 23, 856.—The coagulation of ovalbumin, hemoglobin, paraglobin, gelatin, globin and trypsin was studied with  $\text{Fe}(\text{OH})_3$  sol and NaCl. Gelatin and trypsin flocculate without the addn. of salt, whereas ovalbumin or serum paraglobulin in small concns. diminishes the coagulation value of the  $\text{Fe}(\text{OH})_3$  and hemoglobin and globin have only a protective action. The complex combination between the 2 colloidal particles has a characteristic coagulation value which is independent of that of the  $\text{Fe}(\text{OH})_3$  sol. When this is lower than that of the pure sol there is always sensitization. The idea of a combination between the 2 colloids finds further corroboration in the fact that  $\text{FeCl}_3$  and protein are likewise flocculated by NaCl, though the pure solns. themselves are not. The coagula, whether obtained with colloidal  $\text{Fe}(\text{OH})_3$  or with  $\text{FeCl}_3$ , can be peptized by diln. with  $\text{H}_2\text{O}$  shortly after the pptn., provided the protein concn. is low and a very small salt concn. is required for the pptn. Mixts. of  $\text{Fe}(\text{OH})_3$  sol and protein undergo marked changes in coagulation value, increasing to a max. in the small protein concns. because of the increase in protective action of the protein. The detns. which were made on the H-ion concns. in these mixts. show that this plays a subordinate role in the resulting changes. S. MORGULIS

The influence of different preparations of the quinine group on the enzymic functions of the organism. XI. Comparison of the effects of potassium, sodium and quinine chloride on the pepsin digestion of protein. I. A. SMORODINTZEV AND E. A. SVESHNIKOVA. *Biochem. Z.* 208, 151-63(1929); cf. *C. A.* 23, 2493.—KCl, NaCl and quinine-HCl in *M*/40 concn. inhibit the peptic digestion of hen egg-albumin. KCl and NaCl in all concns. have the same effect on the process, but the *M*/40 quinine-HCl is more strongly inhibiting than an equimol. concn. of the salts. In concns. 0.1 to 0.001 of the above quinine-HCl exerts neither an accelerating nor a retarding action on the peptic digestion. The inhibition of the hen egg-albumin digestion requires only about half as much KCl or NaCl as was found necessary in expts. with edestin. In concns. 10-1000 times smaller than the above neither KCl nor NaCl has any effect on the peptic digestion of the egg albumin. Quinine-HCl which causes inhibition in a concn. of 0.6-1.0% also causes a shift in the  $p_{\text{H}}$  of the medium away from the opt. for the peptic activity, and the inhibitory action can be removed by increasing the acidity of the soln. The therapeutic doses of quinine-HCl will not disturb the progress of peptic digestion in the stomach in the presence of a normal acidity. S. MORGULIS

The parenteral resorption of colloids. II. S. HAYASHI. *Biochem. Z.* 208, 361-7(1929).—Intravenous injection of urease caused a very great increase in the concn. of the enzyme in the serum. This remains unchanged for several hrs., the traces of enzyme disappearing only gradually. Urease injected intraperitoneally likewise accumulates in the serum, but this requires several hrs. and is only obtained with large quantities of injected enzyme. Subcutaneous enzyme injections lead only very slowly to the appearance of traces of urease in the blood. The intraperitoneal absorption of urease seems to depend upon the solvent, concn. and kind of ions as well as H-ion concn. S. MORGULIS

Stereochemical specificity of sulfatase. XI. CLAUDE FROMAGEOT. *Biochem. Z.* 208, 482-9(1929).—By use of the K salt of the sulfuric ester of *p*-sec.-butylphenol it was found that sulfatase either from *Aspergillus* or from pig liver has the same stereochem. effect, always setting free dextro *p*-sec.-butylphenol. The unsplit residue hydrolyzed by boiling with HCl yielded only the levo form. S. MORGULIS

Adrenaline as an oxidation catalyzer. Oxidative deamination of amino acids by means of adrenaline or some simple hydroxybenzenes. GUNNAR BLIX. *Skand. Arch. Physiol.* 56, 131-72(1929).—Glycocoll is oxidized by mol.  $\text{O}_2$  at  $40^\circ$  in the presence of adrenaline, pyrocatechol, hydroquinone, resorcinol, pyrogallol and phloroglucinol, the amino acid becoming deaminated at the same time. As oxidation products,  $\text{NH}_3$ ,  $\text{CO}_2$  and  $\text{HCOOH}$  were found. The above-mentioned substances act as catalysts and apparently in such a way that they first undergo oxidation by mol.  $\text{O}_2$ , and the oxidation product is then reduced by the amino acid. The catalytic reaction requires a definite H-ion concn. opt. of about  $p_{\text{H}} = 10$ . Adrenaline seems to act better than the other catalysts on the acid side of the opt. H-ion concn., and even within the physiol.  $p_{\text{H}}$  range the oxidation of amino acids through the catalysis by adrenaline still proceeds.

at a good rate. Adrenaline and pyrocatechol can also induce the oxidation of alanine, and among the oxidation products, besides  $\text{NH}_3$ ,  $\text{CH}_3\text{COOH}$  also appears. Furthermore, oxidation of valine and leucine was observed in the presence of adrenaline. The exptl. results lead to the conclusion that the effect of adrenaline on the oxidative processes in organs and tissues as well as in the whole organism is to be attributed to a primary oxidation catalysis. The autoxidation of these catalysts (adrenaline, pyrocatechol, hydroquinone) has been studied at different  $p_{\text{H}}$  values and certain numerical relationships have been established. In the autoxidation of adrenaline and pyrocatechol in alk. soln. 3–4 atoms of O are used up per mol. and  $\text{CO}_2$  and  $\text{HCOOH}$  are formed.

S. MORGULIS

**Hydrolysis of gelatin by acids and alkalis.** I. S. YAICHNIKOV. *J. Russ. Phys.-Chem. Soc.* 61, 109–18(1929).—Aside from the polypeptide complex the proteins also contain other org. groups, e. g., that of arginine. Acids do not affect the latter, whereas alkalis decomp. the polypeptide as well as the other org. groups. Consequently proteins are more profoundly hydrolyzed by alkalis than by acids if other conditions (concn., temp. time) are identical. The extent of the hydrolysis has in previous expts. (*C. A.* 21, 3389; 22, 1371) been measured by formolic titration which detd. the quantity of amino acids formed; but it is now realized that one cannot judge of the quantity of protein decompd. by the quantity of amino acids formed, since in the first stage of the hydrolysis albumin is split with production of albumoses and peptones, whereas amino acids are still deficient. It is therefore necessary to det. directly the quantity of protein escaping hydrolysis. The protein is pptd. by the Fassenbender reagent and N is detd. in the ppt. Aside from undecompd. protein, the quantities of peptones and of  $\text{NH}_3$  were also detd. The peptones were detd. by being pptd. together with protein by tannin, detg. in the ppt. the combined N of the peptones and of the proteins and by subtracting the N of the latter. The appended columns of exptl. data show that acids as well as alkalis act on proteins more vigorously at higher temps. and concns. than at lower; this result could be expected. They also show that the action of alkalis is considerably more powerful than that of the acids. The latter result may be explained by either the existence in the protein of groups of the type  $-\text{CH.NH.CH}-$  (in arginine) which are inaccessible to the action of acids and are only affected by boiling alkalis, or by the presence of anhydrides which are more easily acted upon by alkalis than by acids. A lengthy discussion is appended, together with illustrations, of the various methods of graphic representation of the results obtained. It is shown that through the guidance of proper principles in drawing the curves expressing the compn. of the hydrolyzate material may be obtained for the characterization of various proteins. Correction. *Ibid* 467.

BERNARD NELSON

**Structure and characterization of genuine protein substance.** S. P. L. SØRENSEN. *III Nord. Kemistmötet* (Finland) 1926, 72–91(1928).—Investigations during 1924–5 bearing on the structure of proteins are reviewed in Danish. The protein mol. is essentially composed of heterocyclic rings but S. still considers the chief linkage of amino acids as Fischer's peptide. The persistence of P in protein prepn. has been weakened by alc.- $\text{Et}_2\text{O}$  treatment at  $-4^\circ$ . Serum albumin is now known to be P free but the egg albumin must contain P as a component of its mol. Egg albumin soln. kept in ice for 11 years and submitted to alc.- $\text{Et}_2\text{O}$  treatment at  $-4^\circ$  gave a prepn. retaining all characteristic phys. properties but gave 4.7 mg. P per g. N instead of the usual value of 7.3. For protein of mol. wt. 34,000, 1 P to 380 N there should be 5.0 mg. P per g. N. Definitive phys. characteristics for protein identity are discussed. A. R. ROSE

**The influence of the hydrogen-ion concentration upon the enzyme.** IV. The cause of the erepsin-decomposing action of acids. KANICHI HISHIKAWA. *Exptl. J. Digestive Diseases* 3, 167–77(1928).—In acid concns. of 0.25 N to N erepsin is completely decompd. in 1 hr., independently of the degree of the dissoen. of the acid. With more dil. acid, the decompn. velocity is parallel to the degree of dissoen. The amount of decompn. is mostly proportional to the H-ion concn. when the concn. is less than  $2.5 \times 10^{-4}$ . At H-ion concns. greater than  $2.5 \times 10^{-4}$ , the same rate of decompn. is observed for all kinds of acids, because the undissociated acids have also a decompn. action. The resistance of erepsin towards acids is the strongest at  $p_{\text{H}}$  5.5–6.8.

K. SOMEYA

**Donnan's membrane equilibrium.** The change of protein solutions by heating, and its effect upon the membrane equilibrium and the relation between it and the viscosity. KASUHI SHIGI. *Ayoro J. Med.* 25, 706–10(1928); cf. *C. A.* 23, 2630.— $\text{S}^0$  added to egg white the same quantity of N HCl or N NaOH, heated the mixt. at  $490^\circ$  for various lengths of time and examd. the change of the membrane potential. When HCl is added, there is almost no change in less than 60 mins. On heating longer than

80 mins. the potential gradually falls, until it finally becomes zero after 150 mins., showing that the colloid capable of yielding  $RH^+$  or  $ROH^-$  ion is destroyed. When NaOH is used, heating for 10 mins. shows a change in viscosity. K. SOMEYA

The fat-decomposing enzyme. IX. Resolution of lipase into two essential constituents. KENSUKÉ GYOTOKU AND SHOICHI TERAJIMA. *Tokyo J. Med.* 42, 1692-706 (1928).—When a suitable quantity of quinine is added to the lipase soln. obtained by extg. the dry mucous membrane of the stomach of an animal, *e. g.*, when 1% quinine-HCl is added to 5 cc. of the lipase soln. obtained from pig stomach, there is obtained a ppt. of protein which has very little lipolytic action. The supernatant clear soln. is only weakly lipolytic. But when the ppt. and the supernatant clear soln. are mixed an intense lipase action is observed. Thus the stomach lipase is resolved into two constituents, each of which acts only very sluggishly when used independently. Both of these constituents have slight resistance towards acids, but they keep for a longer time than the original lipase soln. The action is most intense in 40 days after resolution. The constituent remaining in the supernatant clear soln. is that which shows the properties peculiar to various lipases, such as the fat-decompg. action and the resistance towards such enzyme poisons as quinine, atoxyl, etc. The component which goes into the ppt. augments the fat-decompg. action, but possesses none of the peculiar properties mentioned above; it appears to be the same for all kinds of lipases. The product obtained by mixing the sol. component from one animal with the insol. component from a different kind of animal has always the properties of the stomach lipase of the animal from which was obtained the sol. component. The splenic lipase also can be resolved into two components, the resolution being rendered especially easy if the protein content is increased by adding beforehand the euglobulin obtained by passing  $CO_2$  into the liver lipase. If the lipases of the stomach and of the spleen are each resolved into their two components and the two different components from each are mixed, there is obtained a strong lipase, the properties of which are detd. by the component present in the supernatant soln.; *i. e.*, the product shows properties of the splenic or the gastric lipase, but never shows properties which are intermediate between the two. The component contained in the ppt. is probably a kind of activator. The proportion of the two components in the mixture has an intimate relation with the strength of the "regenerated" lipase, the action being the most intense with a certain definite proportion. X. The interactivating action of the lipases obtained from the stomach, intestine and duodenum. KENSUKÉ GYOTOKU AND SEIKO MATSUBARA. *Exptl. J. the Digestive Disease* 3, 756(1928).—The lipase action of a mixt. of the intestinal and gastric juice is greater than the sum of the lipase actions of the two; the interactivating action is possessed by both of the liquids, and can be observed when only a very small quantity of one is added to the other. The gastric juice obtained from a patient whose secretion of the juice is hindered has no activating action, so that it is concluded that the activating substance is secreted from the gastric membrane. The substance resists heat. XI. Intestinal lipase. KENSUKÉ GYOTOKU AND SEIKO MATSUBARA. *Tokyo J. Med.* 42, 1892-905(1928).—The lipase value of the intestinal juice of dog is unity per 0.3-0.5 cc., the action being most marked at  $pH$  8.2. Its action is inhibited by quinine a little less than that of the splenic or gastric lipase of dog but it is inhibited strongly by NaF. Even a small quantity of cocaine promotes the reaction. The intestinal lipase of rabbit behaves similarly, but atoxyl does not inhibit the action of the dog lipase, while it does inhibit the action of rabbit lipase. When splenic lipase is mixed with intestinal lipase, the lipase action gradually increases, reaching a max. in 3-5 hrs., and afterwards decreases gradually. The activating action depends upon the quantity of the intestinal liquid added; it manifests itself more quickly at a higher temp. and is not appreciably affected even by heating for 30 mins. at 70-80°. When a small quantity of serum is added to the splenic juice, the progress of activation is slower than with the addn. of the intestinal juice, but the max. is greater than without the serum. Bile further promotes the fat-decomposing action of the splenic lipase, even when it has already been activated to a certain extent by the addn. of the intestinal juice. K. SOMEYA

Biochemical studies on the so-called unsaponifiable substance. II. Unsaponifiable substance, cholesterol and fatty acid in an incubated egg. EIKICHI IGARASHI. *Sei-i-kwai Med. J.* 48, No. 1, 19-32, Abstract sect. 1-2(1929); cf. *C. A.* 23, 1654.—The amts. of unsaponifiable substance and cholesterol in unfertilized eggs laid by a certain hen are nearly the same. Fertilized eggs contain large amts. of unsaponifiable substance and less cholesterol than unfertilized ones. There seems to be no difference in the amino acid content of the 2 varieties. M. H. SOULE

The phase of action of tyrosinase in the reaction with cresol purple. ROBERT

CHODAT. *Compt. rend. soc. physique Geneve* 45, 100-3(1928); *Ber. ges. Physiol. expil. Pharmacol.* 48, 442.—The action of tyrosinase on *p*-amio cresol proceeds in 2 stages: in the first with the coöperation of tyrosinase and in the second without the influence of the enzyme. R. C. WILLSON

Pseudo-peroxidase, a new indirectly oxidizing enzyme, active because of hydrogen peroxide. ROBERT CHODAT. *Compt. rend. soc. physique Geneve* 45, 103-7(1928); *Ber. ges. Physiol. expil. Pharmacol.* 48, 442.—An emulsion of the rhizome of *Cyperus esculentus* L. reacts with *p*-cresol with the formation of a carmine-red water-sol. dye. C isolated this enzyme, which he called pseudo-peroxidase, and found it thermostable. It has no action on tyrosine. R. C. WILLSON

BECHHOLD, H.: *Die Kolloide in Biologie und Medizin*. 5th ed., revised. Dresden and Leipzig: Verlag von Theodor Steinkopff. 586 pp. M. 32; bound, M. 35.

PREIFFER, HANS: *Wissenschaftlichen Forschungsberichte. Band XXI. Elektrizität und Eiweisse, insbesondere des Zellplasmas*. Dresden and Leipzig: Verlag von Theodor Steinkopff. 149 pp. M. 10; bound, M. 11.50.

## B—METHODS AND APPARATUS

STANLEY R. BENEDICT

Simple methods for the estimation of sugar in urine. K. BODENDORF AND A. KOWNATZKI. *Apoth. Ztg.* 44, 636-7(1929).—To 20 cc. of the sample add 2 g.  $\text{Hg}(\text{OAc})_2$  and 2 drops  $\text{AcOH}$ , shake, and after 10 mins. pass through a dry filter. To eliminate the Hg add 1 drop concd.  $\text{HCl}$ , 3 g. Zn dust and a trace of  $\text{CuSO}_4$ , let stand 20-30 mins., filter, and test the clear filtrate with  $\text{SnCl}_2$  for the presence of Hg (in the case of high glucose content, dil. the filtrate with 2 to 3 parts of  $\text{H}_2\text{O}$ ). To 20 cc. freshly prepd. Fehling soln. in an Erlenmeyer flask, add 5 cc. of the dild. urine and a trace of kieselguhr, heat to boiling, continue to boil very gently for 2 mins. Add 30 cc. of  $\text{H}_2\text{O}$ , allow the ppt. to subside, filter rapidly through a moistened folded filter into a 100-cc. graduated cylinder, wash with a few drops of  $\text{H}_2\text{O}$  and fill to the mark. In a 2nd cylinder of exactly like character contg. 80-90 cc. of  $\text{H}_2\text{O}$ , add Fehling soln. drop by drop until the degree of color (against a white background) in both cylinders is the same. The amt. of Fehling soln. consumed (b) added to the 2nd cylinder subtracted from 20 cc. gives the amt. of Fehling soln. expended in reduction. W. O. EMERY

A simple method for the estimation of blood urea applicable at the bedside. HARENDA NATH MUKHERJEE. *Indian Med. Gaz.* 64, 252-5(1929); cf. *C. A.* 23, 2454.—Urea is estd. by pptn. with xanthidrol in alc. soln., as dixanthidryl urea. The turbidity produced by this ppt. in  $\text{CH}_3\text{COOH}$ , in which the excess of reagent is sol., forms a basis of comparison with prepd. standards. FREDERICK G. GERMUTH

The influence of hydrocyanic acid fumes on the color of death spots. W. LAVES. *Deut. Z. ges. gericht. Med.* 13, 261-9(1929).—It is difficult to distinguish the red color in death spots produced by cyanogen poisoning from that produced by HCN. When there is no access of  $\text{O}_2$ , the marks are gray violet. FRANCES KRASNOW

Theory and technic concerning the demonstration of oxygen in lung and intestinal gases of the cadaver. F. DYRENFURTH. *Deut. Z. ges. gericht. Med.* 13, 287-90(1929), cf. *C. A.* 23, 1921.—Discussion. FRANCES KRASNOW

A modified Haldane gas-analyzer for use with small volumes of gas. H. C. BAZETT. *Am. J. Physiol.* 86, 556-64(1928).—A modified Haldane analyzer is described, utilizing some of Krogh's modifications, and designed to analyze mixts. of  $\text{O}_2$  and  $\text{CO}_2$  with a neutral gas, when the vol. available is 2.0 cc. or less and the % of any of the gases varies from 0 to 100. J. F. LYMAN

Improvements of the Welcker method for the determination of the total blood volume—the relation of the blood volume to body weight and surface of the pigeon. O. W. BARLOW AND M. S. BISKIND. *Am. J. Physiol.* 86, 587-93(1928).—The red cell count and sp. gr. of the blood are detd. The animal is decapitated and the hemorrhage blood collected and measured. The circulatory system is then washed by perfusion with 0.85%  $\text{NaCl}$  and the blood content of the perfusate detd. from its vol. and a comparison of its red cell count with that of the original blood. Blood wt. of normal pigeons is 6.5% of the gross body wt.; but total blood vol. is more closely assocd. with body surface rather than with body wt. J. F. LYMAN

Regulation of respiration. XX. A quinhydrone electrode vessel and adapter and

suitable for samples of 0.05 to 0.2 cc. is described, together with a bakelite adapter and 1 cc. syringe for transferring samples without loss of  $\text{CO}_2$ . J. F. LYMAN

An apparatus for the continuous recording of the oxygen consumption of small animals. A. N. RICHARDS AND L. W. COLLISON. *J. Physiol.* 66, 299-306 (1928).—The exptl. animal (small rabbit, guinea pig or rat) is placed in a small closed chamber and the  $\text{CO}_2$  and  $\text{H}_2\text{O}$  which it produces are absorbed by soda lime.  $\text{O}_2$  bubbles in through paraffin oil to keep the pressure const. in the chamber, and the entrance of each bubble is recorded on a drum. The  $\text{O}_2$  consumption is detd. from the rate of formation of the bubbles. J. F. LYMAN

The determination of cholesterol in biliary calculi. MARIO AIAZZI MANCINI *Biochim. terap. sper.* 16, 9-14 (1929).—The author proposes 2 methods: (1) Gravimetric. The pulverized calculi are extd. in a Soxhlet app. with  $\text{Et}_2\text{O}$ . The solvent is distd off and the residue dried at  $80^\circ$  to const. wt. The residue is dissolved in benzene to which is added an amt. of metallic Na equal to the wt. of the residue. Enough anhyd.  $\text{EtOH}$  is added to bring the metallic Na in soln. and form Na ethylate. The soln. is then placed on the water bath and refluxed for 2 hrs. to saponify the fats. The material is cooled, filtered and the ppt. washed carefully with small quantities of benzene. The benzene filtrate and washings are placed in a separatory funnel and shaken with several portions of distd.  $\text{H}_2\text{O}$  until the aq. layer is no longer alk. The benzene which contains only the cholesterol is transferred to a tared flask, the benzene is distd. off and the residue dried in the oven. The criterion of purity is the m. p. Duplicate detns. are made. (2) Volumetric. If the material available is insufficient for duplicate tests, or if the m. p. of the cholesterol residue is not correct, the volumetric method is preferable. The benzene residue is weighed and treated with  $1\frac{1}{2}$  times its wt. of  $\text{Ac}_2\text{O}$  in the presence of  $\text{NaOAc}$  which acts as a catalyzer. The material is refluxed for 4 hrs. to form  $\text{Ac}$  derivs. On cooling, it is filtered by suction, the ppt. is washed with warm  $\text{H}_2\text{O}$  made slightly alk. with  $\text{NaHCO}_3$ , and then with distd.  $\text{H}_2\text{O}$  until the washings are absolutely neutral. The residue is transferred to a flask, and an accurately measured quantity of 0.5  $N$  alc.  $\text{KOH}$  is added. It is then refluxed for 5 hrs. The acetylcholesterol is sapond. and free cholesterol is formed. On cooling, the material is filtered, washed carefully with  $\text{EtOH}$  and the excess  $\text{KOH}$  titrated with 0.5  $N$   $\text{HCl}$ , phenolphthalein being used as an indicator. Each cc. of 0.5  $N$   $\text{KOH}$  consumed corresponds to 0.193 g of cholesterol. PETER MASUCCI

Extraction and analysis of gases from blood. Applications. E. KOHN-ARREST *Chimie & industrie* Special No., 142-6 (Feb., 1929); cf. *C. A.* 19, 664, 837. Further improvements have been made in the app., simplifying its setting up, enabling the vacuum to be maintained and eliminating joints. The app. and the technic of its manipulation are described, and the results obtained are briefly discussed. A. P.-C.

Device for ascertaining the acid content of gastric juices. MAX DWORZAN. *Ger* 475,767, Feb. 14, 1928.

## C—BACTERIOLOGY

CHARLES B. MORREY

Bactericidal action of acetic acid. WALTER OBST. *Deut. Essigind.* 33, 129-31 (1929).—A review of previous work on the disinfectant action of  $\text{AcOH}$ . Attention is directed to the need of more exact expts. in this direction. W. O. E.

The cultivation of *Endameba gingivalis* (Gros) from the human mouth. CHARLES A. KOFOID AND HERBERT G. JOHNSTONE. *Am. J. Pub. Health* 19, 549-52 (1929).—The authors use Locke's egg albumin (L. E. A.) medium which consists of coagulated egg slants (contg. a small quantity of Locke's soln.) with the addn. of 6-10 cc. of Locke's albumin soln. J. A. KENNEDY

The nature of salt hydrolysis of starch considered in the light of the influence of salt on the development of bacteria. MORIO YASUDA. *J. Biochem. (Japan)* 10, 259-76 (1929).—In expts. with starch and either neutral salt or peptone the hydrolysis is due exclusively to the development of microorganisms. The organisms were isolated in pure culture. Salt strongly affects their amylolytic power, and their development was directly dependent upon the salt concn. Multivalent cations even in quantities scarcely demonstrable chemically have a strong influence on their development. Furthermore, these multivalent cations have a very favorable effect on the  $\text{O}_2$  transfer to the microorganisms, as could be shown by expts. on the oxidation of  $\text{FeSO}_4$ . S. M.

Slime formation by *Streptococcus hemolyticus*. MARC. OPPENHEIM. *Centr.*

*Bakt. Parasitenk.*, I Abt., 111, 83-92(1929).—The formation of a mucosus type of growth prevents hemolysis. It is not known whether the slime prevents hemolysin formation, adsorbs it, or directly neutralizes it. Ten strains of *Streptococcus mucosus* changed into *Streptococcus hemolyticus* after repeated transfers on plates made with serum-free erythrocytes.

JOHN T. MYERS

The anaerobic cultivation of *B. influenzae* (Pfeiffer). ADOLPH EHRUND. *Centr. Bakt. Parasitenk.*, I Abt., 111, 195-206(1929).—The influenzae bacillus will grow anaerobically in the presence of the V factor found in plant exts. The presence of the X factor favors indole formation but V alone hinders it.

JOHN T. MYERS

A contribution to anaerobic culture methods. KURT TRAUTWEIN. *Centr. Bakt. Parasitenk.*, II Abt., 77, 551-7(1929).

JOHN T. MYERS

Proteolysis and the selective destruction of amino acids by *Clostridium sporogenes* and *Clostridium histolyticum*. M. W. MEAD, JR. AND C. G. KING. *J. Bact.* 17, 151-61 (1929).—*Cl. sporogenes* and *Cl. histolyticum* growing in protein media tend to utilize or destroy tyrosine to a greater degree than histidine. *Cl. sporogenes* is more active with both amino acids than is *Cl. histolyticum*. The action of the organisms is selective toward these 2 amino acids in fibrin and edestin media. The proteolytic power of *Cl. histolyticum* is greater than that of *Cl. sporogenes* as measured by the production of  $\text{NH}_3$ . Tyramine appears in the cultures but not to the extent that tyrosine disappears; hence the latter is evidently decarboxylated and then further consumed in putrefaction. Histamine was not found in any cultures. The 2 organisms give rise to a  $\text{pH}$  of 7.5 to 8.2 in protein-rich media. In *Cl. histolyticum* cultures, the  $\text{H-ion}$  concn. is such as to facilitate tyrosine crystn. when it is set free in the medium.

JOHN T. MYERS

A review of the development and application of physical and chemical principles in the cultivation of obligately anaerobic bacteria. IVAN C. HALL. *J. Bact.* 17, 255-301 (1929).—A very complete review and bibliography.

JOHN T. MYERS

Further observations on the oxidation by bacteria of compounds of the *p*-phenylenediamine series. S. ELLINGWORTH, J. M. McLEOD AND J. GORDON. *J. Path. Bact.* 32, 173-83(1929).—The oxidations of the various substitution products of *p*-phenylenediamine-HCl produced by chem. oxidizing agents resemble closely those produced by certain bacteria. The facility of oxidation of such diamines increases with the no. of Me groups in the mol. In the absence of free O, the various diamines have a roughly similar toxicity for bacteria. When O has free access to bacterial colonies previously exposed for a few secs. to a soln. of a diamine, the monomethyl compd. is the least, and the tetraethyl the most, toxic. Toxicity varied with the speed with which the colonies develop a black tint. A 0.5% soln. of the tetramethyl compd. is best for diagnostic bacteriology. The species capable of oxidizing the tetra compd. also reduce it; hence the blue-violet color fades at varying speeds with different species. Those diamines which produce a black color do not fade as they kill the bacteria; hence there can be no subsequent reduction. This compd. indicates the oxidizing activity of a no. of bacteria not picked out by the other diamines, notably *B. pertussis* and *B. influenzae*, of which the former is the more active. All attempts to prep. media contg. diamines on which oxidizing bacteria would develop colored colonies as they grow have failed.

JOHN T. MYERS

Changes of the phagocytic capacity in vitro through the influence of dextrose on bacteria, serum and leucocytes. ALESSANDRO VASATURO. *Folia med.* 14, 539-73 (1928); *Ber. ges. Physiol. expil. Pharmacol.* 47, 167.—Dextrose acting on leucocytes or serum promotes phagocytosis but is inhibiting to bacteria.

R. C. WILLSON

Demonstration of the formation of vitamin B by *Bacillus vulgatus* Migula by means of a new and reliable method. MARTIN SCHIEBLICH. *Biochem. Z.* 207, 458-61(1929).—Exptl. evidence is offered to prove that *B. vulgatus* Migula grown on an artificial medium free from vitamin N produces this vitamin as can be demonstrated by feeding to young rats cultures of these organisms.

S. MORGULIS

The classification of the micrococci. G. J. HUCKER. *Centr. Bakt. Parasitenk.*, I Abt., 111, 9-22(1929).—The article contains a detailed description of the biochem. actions of a no. of common micrococci.

JOHN T. MYERS

A new dye medium for differentiation between paratyphoid bacilli A and B. KENRO ISHIYAMA. *Centr. Bakt. Parasitenk.*, I Abt., 111, 24-6(1929).—The medium was: agar, 100 cc.; 1.2% crocein in distd. water, 1.5 to 2.0 cc. Paratyphosus B destroys the color in 12 hrs., while paratyphosus A requires at least 3 days.

JOHN T. MYERS

*Bacterium typhosus hemolyticus*. Experimental production of a new type through the action of bacteriophage. CURT SONNENSCHNEIN. *Centr. Bakt. Parasitenk.*, I Abt., 111, 177-80(1929).—When acted on by bacteriophage, *B. typhosus* acquires the power to produce a hemolysin for sheep erythrocytes.

JOHN T. MYERS

Alkaline media and their effect upon *Bacillus acidophilus* and its products in the mouth (BADANES) 17.

MORREY, CHAS. B.: *The Fundamentals of Bacteriology*. 4th ed., revised. Philadelphia: Lea & Febiger. 347 pp.

## D—BOTANY

THOMAS G. PHILLIPS

Carbon nutrition of some algae isolated from soil. B. M. B. ROACH. *Ann. Botany* 41, 509-17(1927); cf. *C. A.* 20, 2180.—A study of 5 species of soil algae, grown in pure culture on media contg. mineral salts with 1% of various sugars, shows that all the species were capable of growth in complete darkness, provided that a suitable org. compd. was present. The requirements of the individual species and their responses to different conditions were, however, widely different, and it is not justifiable to regard the soil algae as a homogeneous physiol. unit. B. C. A.

A kinetical explanation of photosynthesis based on Harder's results with *Fontinalis*. J. C. GHOSH. *Jahrb. wiss. Botan.* 69, 572-86(1928).—On the basis of Willstätter and Stoll's hypothesis for the mechanism of photosynthesis G. shows that a kinetical explanation is possible which agrees with Harder's theory (*C. A.* 16, 3929) for the assimilation of carbohydrates. When either the concn. of  $\text{CO}_2$   $1/C$  or the light intensity  $1/I$  was plotted against the velocity of the reaction  $1/V$ , a straight-line curve was obtained. These results do not agree with Blackman's explanation that the velocity of reaction is proportional to the concn. of  $\text{CO}_2$  up to a certain point and thereafter is not. The equation for the effect of varying temps. has not as yet been worked out. A. E. H.

Influence of temperature and nutrients on the reaction velocity of diastase in cultures of *Aspergillus niger*. ELISABETH LUIPPOLD. *Jahrb. wiss. Botan.* 70, 26-54 (1929).—The reaction velocity for the digestion of starch by diastase was detd. at 15° and 35°. The temp. quotient for this reaction was not altered, providing the nutrients and the  $p_H$  of the medium were the same at both temps. When, however, either the  $p_H$  or the nutrients was altered, the value of the temp. quotient was changed. Since the  $p_H$  of the medium was altered by a change in temp., it follows that temp. exerts an indirect but not a direct influence on the temp. quotient. The max. value for the quotient (5.1) was obtained at  $p_H$  5.2-5.4 in solns. contg. carbohydrates as a source of C. A. E. HITCHCOCK

Physiological investigations of *Plasmopara viticola* during infection processes. KARL ARENS. *Jahrb. wiss. Botan.* 70, 93-154(1929).—Zoospores of *Plasmopara viticola* reacted positive toward  $\text{PO}_4$  and  $\text{OH}$  ions, and negative toward  $\text{H}$  ions. The presence of phosphatides on the surface of grape leaves and the outflow of gaseous materials through the stomates are believed to offer surface tension effects that are favorable for the chemotaxis of the zoospores. Since a similar reaction (the accumulation of zoospores around stomates) occurs on the leaves of many kinds of plants and since similar surface tension effects are produced in dil. soln. of several different compds., the substance responsible for the chemotaxis is believed to be non-specific. A. E. HITCHCOCK

The influence of colloidal substances on the growth of roots. B. NIELEWSKI AND A. KRAUSE. *Jahrb. wiss. Botan.* 70, 158-62(1929).—In colloidal solns. of agar, starch, and *m*-ferrioxhydrocol roots of beet seedlings grew more rapidly than in distd.  $\text{H}_2\text{O}$ . These results indicate that soil colloids may be of more importance in plant growth, aside from any nutritive value, than has previously been supposed. A. E. H.

The occurrence and significance of tannin in plants. HANNA HUBER. *Jahrb. wiss. Botan.* 70, 278-325(1929).—The quant. extn. of tannin from different plants required different procedures. A 40% soln. of acetone extd. 100% of the tannin from acorns of *Quercus pedunculata*. Germinating seeds of *Q. ilex* var. *ballota* contained a greater amt. of tannin than dormant acorns. Although 30% of the tannin was found in the cotyledons, it is not known whether or not tannin functions as a reserve material. The non-toxic effect of tannin in the cell is probably due to its occurrence as an insol. adsorption product. A. E. HITCHCOCK

The relation between protein content and size of chloroplasts in leaf cells of *Pelargonium zonale*. WALTER SCHUMACHER. *Jahrb. wiss. Botan.* 70, 389-433(1929).—No correlation was found between the protein N content and size of chloroplasts in leaf cells of *Pelargonium zonale* after the leaves had been in darkness 1-3 days. These results do not substantiate the theory proposed by Meyer, Molisch and Ullrich that such a correlation existed and could therefore account for the localized synthesis of proteins in the chloroplasts. A. E. HITCHCOCK

Conditions of coremia formation by certain fungi. A. YA. MANTSEFEL AND V. N.

SHAPOSHNIKOV. *Trans. Sci. Chem.-Pharm. Inst. (Moscow)* 1927, No. 18, 31-47.—*Penicillium arenarium* Shaposhnikov and Manteifel, *P. luteum* Link, *P. expansum* Thom (Link) and *Botrytis bassiana* Bals. responded differently to media for the formation of coremia. *P. arenarium* forms coremia when the N content of the substrate is increased. The other two penicillia do not respond to N increase and the production of coremia by them could be traced to the split products in the media produced by the metabolism of the first crop of fungi. The power of *Botrytis* to form coremia depends on the moisture conditions. The cultures are described in detail and photographic illustrations given.

Some effects of the waxy gene in maize on fat metabolism. F. A. ABEGG. *J. Agr. Research* 38, 183-93(1929).—Nonwaxy and waxy maize grain contain 6.5 and 7.3% crude oil, resp. The corresponding endosperm and embryo tissues of the resp. grains contain 1.05 and 34.0 and 1.5 and 34.3% crude oil. The av. acid value of the Et<sub>2</sub>O-sol. crude oil from nonwaxy grain was 13 and from waxy 34. The av. acid values and saponos. of the fats from nonwaxy endosperm tissues were consistently lower than those from waxy. The above differences appear to be restricted to the endosperm tissues. Since the effects of the waxy gene on carbohydrate metabolism in the plant are evident in both endosperm and pollen these effects are considered primary while those on fat metabolism are secondary. It is thought that the waxy gene is connected with the synthetic and hydrolytic powers of maize endosperm lipase. It appears that the waxy type lipase does not effect a condensation of fatty acids with glycerol to the same extent as does the nonwaxy.

Inheritance of yield and protein content in crosses of marquis and kota spring wheats grown in Montana. J. ALLEN CLARK AND KARL S. QUISENBERRY. *J. Agr. Research* 38, 205-17(1929).—Awnleted selections of crosses averaged higher in yield but lower in protein content than awned selections. The crude protein content of F<sub>2</sub> and F<sub>3</sub> plants was positively correlated to a highly significant degree.

The influence of growth-promoting substances of the nature of vitamin D on yeast cells. HANS LECROIX. *Centr. Bakt. Parasitenk.* 11 Abt. 76, 417-28(1929).—It was not possible to grow yeasts in pure mineral solns. Growth of yeast is enhanced by exts. of fruits and vegetables, and especially sprouting grains.

The relation between maximum rate of photosynthesis and concentration of chlorophyll. ROBERT EMERSON. *J. Gen. Physiol.* 12, 609-22(1929); *Proc. Natl. Acad. Sci.* 15, 281-4.—The max. rate of photosynthesis in the alga, *Chlorella vulgaris*, is a smooth function of the chlorophyll content. A method is given for varying the chlorophyll content per unit vol. of alga cells with other factors const.

Photosynthesis as a function of light intensity and of temperature with different concentrations of chlorophyll. ROBERT EMERSON. *J. Gen. Physiol.* 12, 623-39(1929).—Photosynthesis reaches its max. rate at approx. the same light intensity for all chlorophyll concns. studied, and shows the same relation to temp. over this range of concn. The temp. characteristic ( $\mu$  of the Arrhenius formula) decreases gradually as the temp. rises. The lower the concn. of chlorophyll the greater is the depression of rate of photosynthesis by HCN. Photosynthesis probably involves an autocatalytic reaction and chlorophyll must play a part in the process other than that of absorption of light.

Catalase activity and sex in plants. W. H. CAMP. *Am. J. Botany* 16, 221-4(1929).—The catalase activities of various tissues from 12 species of plants having bisporangiate, monosporangiate or dioecious types of inflorescences were compared with the sexual expression. In all species examined it was found that tissues related to the staminate or male structures, either purely vegetative or floral, showed a distinctly greater catalase activity than tissues related to the carpellate or female structures of the same species. It was also found that, in general, floral structures showed a greater difference than vegetative parts.

Lateral transfer of lithium nitrate in *Salix*. E. T. BODENBERG. *Am. J. Botany* 16, 229-39(1929).—LiNO<sub>3</sub>, when introduced into stems by a normal mode of entrance through roots growing on one side of these stems, apparently was unable to pass laterally through the stems. Spectroscopic tests for the detection of the salt were made in the leaves of transpiring branches attached to the stems and at opposite sides from the absorbing roots. The time allotted was as much as 295 hrs. The expts. were not continued longer because of the possibility of new tissue being proliferated to bridge the gap in the conducting system between roots and branches. The same results were obtained when H<sub>2</sub>O was supplied to the stems by means of a wick attached to a cut on the upper side as when the stems were kept constantly moist by wet sphagnum. The indication is that mineral salts are not normally transferred across the stems of woody

plants, though the evidence may not be entirely conclusive. On the other hand it appears that a lateral movement of water may take place. J. J. SKINNER

Heat-resistant races of yeast. JULIUS RENNING. *Ber.* 62B, 1267-70(1929).—Methods are detailed for the comparison of yeasts, both spores and vegetating cells, for their fermentation power at higher temps. J. J. WILLAMAN

Role of the cytoplasm in starch formation. A. MAIGE. *Compt. rend.* 188, 1058-60 (1929).—The cytoplasm can, by physico-chem. variations, affect starch formation in 2 ways: unfavorably, by acting toxically on the starch plastid; and favorably, by conditioning in the plastid stroma a physico-chem. change which induces a conversion of sugar to starch. J. J. WILLAMAN

Foliar diagnosis and its degree of surety. H. LAGATU AND L. MAUME. *Compt. rend.* 188, 1062-4(1929).—A diagnosis of the nutrient condition of a plant is made by analyzing the leaves for N, K<sub>2</sub>O and P<sub>2</sub>O<sub>5</sub>, and comparing the values with those of normal plants. The trustworthiness of the results are dependent on the degree of soil (or culture) homogeneity. J. J. WILLAMAN

Glutathione in plants. W. H. CAMP. *Science* 69, 458(1929).—Fink's micro-method for glutathione, using Na nitroprusside, was adapted for its detection in plants. It was found in the stem apex of young sunflowers (*Helianthus annuus*); it was especially characteristic of staminate tissue in arum (*Alocasia odora*), and in corn (*Zea mays*). "The nitroprusside reaction, indicating glutathione, is thus helpful as an indicator of certain chemical reactions in the cells, and may be used to advantage in measuring the metabolic level of various tissues during the ontogeny of the plant." J. J. W.

Hexamethylenetetramine and formaldehyde are nutrients for beans. I. MARRASSÉ. *Compt. rend.* 188, 1006-7(1929).—Bean embryos, sepd. from the cotyledons and freed from starch by sprouting in the dark, were placed in solns. of hexamethylene tetramine (0.1 to 0.3 g. per l.) and of HCHO (0.16 to 0.6 g. per l.). Judged both by the formation of starch and by the growth of the nuclei, both substances proved to have nutritive value. The optimum concn. of the first was 0.2 g. and for the second, 0.16 g. per l. J. J. WILLAMAN

Constitution of pine wood lignin. VIII. The nutritive sap of the pine (KLASON) 10. Non-tannin substances in the extract of the root of badan. I. Bergein (CHICHIBABIN, et al) 10. Conjugated double bond. IX. The coloring matter in *Physalis alkekengi* and *Physalis franchetti* (KUHN, WIEGAND) 10.

## E—NUTRITION

PHILIP B. HAWK

The sterols isolated from several vegetables. MIZUHO SUMI. *Bull. Inst. Phys. Chem. Research* (Tokyo) 8, 228-33(1929); *Abstracts sect. 2*, 30.—S. investigated the sterols isolated from (1) *Enteromorpha compressa*, (2) *Cytophyllus fusiforme* Harv., (3) *Digenea simplex* C., (4) *Osmunda regalis* L., (5) spore of *Lycopodium clavatum*, (6) pollen of *Typha japonica* Miq., (7) seed of *Ginkgo biloba* L. and (8) oil of rice bran. The sterols were all sitosterol. The ergosterol content mixed in these sterols was detd. by the ultra-spectroscopic method. The non-crystd. portions of the unsaponifiable parts of (1), (2), and (3), which were purified by cooling with liquid air, and with digitonin, were tested for the antirachitic property. 0.1 mg. per day of these fractions had the power to prevent rickets in young white rats. G. CALINGAERT

The antirachitic potency of biosterol. SADAYUKI HAMANO. *Bull. Inst. Phys. Chem. Research* (Tokyo) 8, 293-6(1929); *Abstract sect. 2*, 38(1929).—Albino rats were made to suffer from rickets, after having been fed with Steenbock diet No. 2965 during 4-5 weeks. The regular daily dose, 0.1, 0.05, 0.01, 0.001 mg., resp., of biosterol dissolved in linseed oil, was given per rat *per os* for 3 weeks, and then the animals were examd. by radiography. The 6 series of observations on 88 rats in total showed that a daily dose of 0.01-0.05 mg. of biosterol per head was necessary to bring out the healing or preventive effect on the exptl. rickets. Similar expts. were carried out also with the market sample of "Ricken Vitamin A," of which the daily dose of 2 mg. was found sufficient to attain a similar effect. G. CALINGAERT

The oryzatoxin theory. MASATARO MIURA. *Bull. Inst. Phys. Chem. Research* (Tokyo) 8, 311-8(1929); *Abstract sect. 2*, 39-41(1929).—A large no. of feeding expts. on pigeons, *Uroloncha domestica* Flower, and albino rats were carried out. (1) The typical polyneuritis may be brought about by the EtOH-extd. polished rice or by the

similarly treated potato-starch diet, and it can be cured or prevented by administration of vitamin B. (2) With Simonnet's diet pigeons suffer from spasms in a very high percentage of cases and in some the onset is remarkably delayed. (3) With fats and EtOH-sol. matters removed from the same diet, the pigeons all died of marasmus. (4) The compn. and the relative proportions in the diet seem to affect the length of the incubation period of polyneuritis in pigeons. (5) The addn. of EtOH ext. of polished rice or its petroleum ether fraction does not quicken the onset of the disease in pigeons. (6) For the growth and well-being of albino rats, a supply of vitamin B is necessary, even when EtOH-extd. rice or EtOH-extd. potato starch is used as the carbohydrate moiety of a synthetic diet. (7) Though the onset of polyneuritis on a vitamin B-free diet was not affected, in any way, by the addn. of a very minute amt. of vitamin B, a small amt. either of vitamin A or of irradiated or non-irradiated ergosterol, the possibility of the presence in the EtOH ext. of polished rice of some sp. non-toxic substance or substances which increase the requirement for vitamin B in test animals cannot definitely be denied. (8) EtOH ext. of polished rice shows slight protein reactions, and contains a small amt. of ash and vitamin B in addn. to a large amt. of fats. Potato starch also contains vitamin B, but much less. (9) Vitamin-B-free diet does not necessarily produce the typical picture of polyneuritis. These results indicate that the expts. carried out by Teruuchi do not conclusively prove the existence of a toxin (oryzatoxin) in the EtOH ext. of polished rice. (10) M explains briefly why he made use of nervous symptoms, especially the spasms and accompanying characteristic rapid fall of body temp., as the criterion of the onset of the disease, and also, as a further check, the effects on these symptoms of subsequent administration of vitamin B.

Lumière's claim to have produced the classical symptoms of polyneuritis in pigeons on a diet rich in vitamin B but quantitatively insufficient is not confirmed. G. C.

**A peculiar disturbance of carbohydrate metabolism.** RUDOLF SCHÖNHHEIMER. *Z. physiol. Chem.* 182, 148-50(1929).—The autopsy of a 7 $\frac{3}{4}$  year old girl who had died of grippe showed enormous enlargement of liver and kidneys. These organs contained enormous deposits of glycogen. On the dry basis the glycogen content of the kidney was 36.82% and of the liver 33.72%. This value for the liver is almost the max. ever obtained by forced feeding of animals with carbohydrate, but so high a value for the kidney is wholly without precedent. The glycogen accumulation was probably due to some disturbance which prevented enzymic breakdown of the glycogen. Six days autolysis of the liver failed to diminish its glycogen content, but glycogen prep. from this liver was readily hydrolyzed by livers obtained from other cadavers. A. W. DOX

**Research findings on corrosion and vitamin destruction.** E. F. KOHMAN. *Canning Age* 9, 227-31(1928); *Expt. Sta. Record* 59, 94.—A brief summary of investigations on the vitamin C content of canned apples (*C. A.* 19, 543), peaches (*C. A.* 20, 1432), and strawberries (*C. A.* 22, 1995), with special emphasis on the relation of O to destruction of vitamin C and the means required with different fruits to exhaust the O present in the fruit before canning if losses of vitamin C are to be prevented. A similar relationship exists between the O content of fruit and the corrosion of cans; recent studies on factors involved in corrosion are summarized. In colored fruits canned in stainless steel the color is preserved better than in enameled cans. A preliminary report is included on the vitamin content of tomato concentrate. No appreciable loss in vitamins A and B was found to take place during the concn., but there was some loss in vitamin C. This loss is not, however, in proportion to the concn. Tomato pulp is thus considered to be somewhat richer in vitamin C than raw tomatoes, wt. for wt., and several times richer in vitamins A and B. H. L. D.

**Growth, reproduction and longevity of experimental animals as research criteria in the chemistry of nutrition.** H. L. CAMPBELL. *Diss., Columbia Univ., N. Y.*, 1928, 39 pp.; *Expt. Sta. Record* 59, 789-90.—The purpose was to demonstrate the possibility of forming a quant. estimate of the value of different approx. adequate diets by long-time feeding expts. on rats for comparisons of the relative growth of the young animals, the vigor of the adults, and the relative longevity. It is concluded that properly standardized animals under carefully controlled conditions may be used as criteria in nutritional research, growth, reproduction and longevity. "This promises to be of special value when the field of investigation is that which approaches more or less closely to the adequate in nutrition, in which short time expts. are of little value." H. L. D.

**The vitamin A and vitamin D content of cod-liver meal.** E. M. CRUICKSHANK.

with skim milk *ad libitum*, being used. In the vitamin D expts. the corn was yellow and in the A expts. white. One % of cod-liver meal was sufficient to protect the chicks against rickets and from 7 to 10% to meet the requirements for vitamin A. Ophthalmia was not observed in the vitamin A deficiency, but respiratory and lung trouble, with nodular lesions of mouth and pharynx, and characteristic changes in the kidneys, in which the ureters and renal tubules were filled with an accumulation of urates, were observed. H. L. D.

The vitamin A and vitamin D content of cod-liver meal. E. M. CRUICKSHANK, E. B. HART AND J. G. HALPIN. *Poultry Sci.* 7, 9-16(1927); *Expt. Sta. Record* 59, 465; cf. preceding abstr.—Cod-liver meal contg. 45% of oil and 43% of protein was tested for its vitamins A and D potency. In testing the vitamin D content 9 groups of chicks were fed for six weeks on a basal ration of 97 parts of yellow corn, 2 parts of  $\text{CaCO}_3$ , 1 part of salt, and skimmed milk *ad libitum*. To the basal ration were added in the various groups ultra-violet light, cod-liver oil, and cod-liver meal in amts. varying from 1 to 10%. In testing the vitamin A content 10 groups of chicks were fed a basal ration of 92 parts of white corn, 5 parts of yeast, 2 parts of  $\text{CaCO}_3$ , 1 part of salt, and skim milk *ad libitum*. To the basal ration in the various groups were added ultra-violet light, cod-liver oil, and cod-liver meal in amts. varying from 1 to 10% and cod-liver meal and ultra-violet light in combination. Even 10% of the cod-liver meal used did not furnish sufficient vitamin A to protect against rickets, although chicks receiving this amt. survived longer and did not show pathol. symptoms in such a marked degree as those receiving less meal. The cod-liver meal used contains sufficient vitamin D to promote good calcification even when fed at a level of 1%, but not enough vitamin A to protect birds from vitamin A deficiency even when fed at a 10% level. H. L. D.

Vitamins. L. KOFLER. *Pharm. Monatsh.* 10, 57-9(1929).—An address. W. O. E.

Variations in the amounts of the antirachitic vitamin in different samples of cod-liver oil, milk and butter. KATHARINE H. COWARD. *Quart. J. Pharm.* 1, 534-8(1928).—Among the samples of 4 selected oils examd. the vitamin D varied from 50 to 150 units of antirachitic activity per g. A biol. test is needed. 0.4 g. of butter given as a daily dose for 10 days usually produces a degree of healing in exptl. rickets comparable with that of one of the doses of the standard prepn. Two out of 3 samples of milk examd. were almost entirely lacking in vitamin D. W. O. E.

Notes on the chemistry of the fat-soluble vitamins in cod-liver oil. A. L. BACHARACH AND E. LESTER SMITH. *Quart. J. Pharm.* 1, 539-45(1928).—Vitamin D is mainly present in cod-liver oil in a form sol. in EtOH, vitamin A in a form insol. in EtOH. Sapon. renders it sol. in EtOH without affecting its vitamin or chromogen activities. It is suggested that the vitamin A is present in cod-liver oil as an ester, and that a portion of the vitamin D is also sometimes present as an ester. W. O. E.

Influence of changes in body weight of the test rats on the accuracy of the assay of vitamin D by means of the line test. KATHARINE H. COWARD AND MARJORIE R. CAMBLEN. *Quart. J. Pharm. and Pharmacol.* 2, 44-7(1929).—From the numerical data obtained and drawings of sections of the bones it appears that an assay of the strength of the com. prepn. examd. can be computed in the usual way in terms of the Society's standard prepn. of irradiated ergosterol. The more interesting factor in the expt. lies in the degree of healing brought about by a more or less temporary loss of wt. in the rats which received no dose of any substance contg. vitamin D. None of the rats was significantly heavier at the end of the expt. than it was at the beginning, and yet a very severe degree of rickets, indicated by the wide metaphyses and very swollen ends of the bones, had been developed in each one. The figures presented show how far slight variations in wt. of the rats during the exptl. period may affect the calcification of the bones during that time. Far greater irregularities in healing are encountered in rats in which the degree of rickets is so slight that the bones are not enlarged at the ends, and the metaphyses are only somewhat (though definitely) wider than normally, a condition ascribable to the irregularities in feeding prior to the exptl. period, and it must be emphasized again that, unless this post-lactation, pre-exptl. period is controlled as carefully as an exptl. period, uniform results cannot be obtained. W. O. E.

Relation of soil fertility to vitamin A content of leaf lettuce. MARIE DYE AND JOHN W. CRIST. *J. Nutrition* 1, 335-8(1929).—Grand Rapids Forcing variety of leaf lettuce was grown in pots contg. 5 lb. of (I) sandy loam soil of very low fertility; (II) soil plus the addn. of 25 g. of pulverized sheep manure and 1 g. of a mixt. of  $\text{KNO}_3$ ,  $\text{CaH}_2\text{H}_2\text{PO}_4$ , and KCl (1:2:1); (III) soil plus 4 g. of the inorg. mixt. but no org. matter. Animal feeding tests for vitamin A were made during a period of 8 weeks.

Ten rats were used for each treatment. The chem. compn. of the plants was detd. after the 8-week period. The chem. analysis of the lettuce did not aid in interpreting the results. The total gains in wt. were I, 58.2 g.; II, 73 g.; III, 82.4 g. The vitamin A content increased with plant vigor, robustness and with the greenness of the lettuce. Conclusion: The vitamin A content is assocd. with the degree of greenness but not necessarily with vigor apart from differences in chlorophyll. Further expts. on this point are under way.

The action of irradiated ergosterol in the rabbit. MAURICE I. SMITH AND E. ELVOVE. *U. S. Pub. Health Repts.* 44, 1245-56(1929).—The action of irradiated ergosterol has been studied in the rabbit with especial reference to its toxicity, its influence upon serum Ca and inorg. phosphate and its influence upon tissue Ca. Repeated administration of 2 mg. and upwards of irradiated ergosterol given orally or intramuscularly to full-grown rabbits may prove fatal in a relatively short time. Doses of 1 mg. or less given 3 to 4 times a week seem to be well tolerated. Large doses of irradiated ergosterol produce a more or less marked hypercalcemia. Small doses produce variable results. The inorg. phosphate of the serum, though subject to considerable normal fluctuations, also appears to be definitely increased under the influence of the larger doses of irradiated ergosterol. Toxic doses of irradiated ergosterol produce great increases in the Ca of certain tissues. The calcifying action of irradiated ergosterol appears to be highly selective, involving certain tissues, *e. g.*, the aorta, kidney and lungs, but not others, *e. g.*, liver or striated muscle. The relation of the hypercalcemia under the influence of irradiated ergosterol to the tissue Ca is discussed.

Digestion from whole plant cells and its significance for the physiology and pathology of digestion in men. VI. Digestion of fat from raw plant tissue. W. HEUPKE AND A. V. MARX. *Arch. Verdauungskrankh.* 44, 23-31(1928); *cf. C. A.* 22, 1601.—Fat found in the whole plant cells (nuts and olives) can be digested (expts. on mice and men). The lipase of the digestion secretions can find its way into the cell. VII. Digestion of starch from raw plant cells. WILHELM HEUPKE. *Ibid* 169-75.—Starch is digested from cells that are not broken mechanically. The diastatic enzymes of the intestinal secretions pass the cell walls of uncooked plants. Different raw starches vary in their availability to digestion.

FRANCES KRASNOW

The value of protein from cacao and cacao products. HANS PULFER. *Arch. Verdauungskrankh.* 44, 115-22(1928).—Cacao and cacao products can be used to supply the protein N in dog and man. Although the fecal discharge is increased as is the case with all plant protein, the utilization of the cacao protein is not markedly reduced. This utilization is increased with continued administration.

FRANCES KRASNOW

Nutritional allergy as a factor in the pathogenesis of initial lung tuberculosis. C. FUNCK. *Arch. Verdauungskrankh.* 44, 356-61(1928).—Report of 2 cases pointing out this relationship.

FRANCES KRASNOW

Nutrition studies in a low protein intake during an interval of 25 months. B. ZUSKIND. *Arch. Verdauungskrankh.* 44, 371-2(1928).—During the first 9 months on a protein intake of 0.69 g. per kg. body wt. there was no change in body wt. In the next 11 months, the protein intake was 0.55 g. per kg. body wt. Slight loss in body wt. was noted. The last 5 months of the expt. showed a loss of 1.5 kg. in wt., the protein intake being 0.58 g. per kg. body wt.

FRANCES KRASNOW

Nitrogen excretion of hogs on velvet-bean rations. EMERSON R. MILLER. *J. Am. Vet. Med. Assoc.* 74, 376-80(1929).—Hogs assimilate a much smaller quantity of N of the velvet-bean than is utilized from other ordinary rations. A relatively large amt. of N is eliminated in the urine.

FRANCIS KRASNOW

Starch digestion in the dog. B. B. ROSEBOOM AND J. W. PATTON. *J. Am. Vet. Med. Assoc.* 74, 768-72(1929).—Dogs are capable of digesting and assimilating starch, both raw and cooked. Their salivary and pancreatic secretions contain amylase.

FRANCES KRASNOW

Studies on the nutritive value of milk. II. The supplementary value of inorganic iron and copper. W. E. KRAUSS. *J. Dairy Sci.* 12, 242-51(1929); *cf. C. A.* 23, 1939.—

Addn. of Fe salts to an exclusive whole milk diet did not prevent anemia. Addn. of Cu salts was beneficial, but addn. of both Cu and Fe salts was very effective. No offspring were produced on this diet, possibly because of a destructive effect of Fe salts on vitamin E. The total nutritive effect, aside from reproduction, of milk obtained under different conditions, might be detd. by the use of a milk diet supplemented with Cu and Fe salts.

AMY LEVESCONTE

**Rickets in rats. VIII. Rickets and tetany.** ALFRED T. SHOHL AND FRANKLIN C. BING. *Am. J. Physiol.* 86, 633-8(1928); cf. *C. A.* 22, 4584.—Rats made rachitic by a high-Ca, low-P diet were cured by (1) cod-liver oil, (2) ultra-violet radiation and (3) added phosphate in the diet. Cod-liver oil or irradiation produced a lessened irritability to galvanic stimuli; the addition of phosphates caused an increased irritability. The condition resulting from the addition of phosphates to the diet of rachitic rats is a transient tetany.

J. F. LYMAN

**The physiology of the vitamins. VI. The effect of insulin on gastric motility in vitamin-B deficiency.** C. J. STUCKY, W. B. ROSE AND G. R. COWGILL. *Am. J. Physiol.* 87, 85-92(1928); cf. *C. A.* 23, 1938.—Gastric motility was definitely lowered in 6 out of 8 dogs suffering from vitamin B deficiency. Insulin injections increased gastric motility of the vitamin-B deficient animals in 25% of the trials (4 out of 16). No relationship between gastric motility and blood sugar level could be demonstrated.

J. F. LYMAN

**Muscle hemoglobin concentration during growth as influenced by diet factors.** G. H. WHIPPLE, A. H. GROTH AND F. S. ROBSCHT-ROBBINS. *Am. J. Physiol.* 87, 185-91(1928).—Pups were fed (1) on a diet unfavorable for blood hemoglobin regeneration and (2) on a diet highly favorable thereto. After 10 weeks feeding no difference in the muscle hemoglobin of the 2 groups was noted. After 15 to 20 weeks the liver-fed pups showed uniformly a distinct increase in blood hemoglobin and muscle hemoglobin concn. above the bread controls, and after 25 to 30 weeks these differences may be more distinct.

J. F. LYMAN

**The effect of yeast feeding on some blood constituents of hens.** A. A. HORVATH. *Am. J. Physiol.* 87, 208-20(1928).—The addn. of active yeast or of taka-diastase to low purine rations fed to hens resulted in a rise of blood uric acid and of plasma inorg. phosphates. Heated (inactive) yeast had little or no such effect. It is suggested that the nuclei of yeast and taka-diastase have the ability to raise the uric acid content of the blood on a low purine diet.

J. F. LYMAN

**The biological value of yeast proteins for the rat.** E. V. STILL AND F. C. KOCH. *Am. J. Physiol.* 87, 225-48(1928).—Raw dried yeast as the only source of protein in a "synthetic" ration for the rat showed a digestibility for proteins of 72%. Cooked yeast showed a protein digestibility of 62%. The biological values of cooked and raw yeast protein as compared with casein were 37.9 and 45%, respectively. The Ca and P balances on the yeast rations were less favorable than those obtained on casein diets.

J. F. L.

**Effect of proteins and vitamins on hemoglobin production in the rat.** G. F. CARTLAND AND F. C. KOCH. *Am. J. Physiol.* 87, 249-61(1928).—See *C. A.* 22, 4583.

J. F. LYMAN

**A short method of calculating energy, protein, calcium, phosphorus and iron in the diet.** EDITH HAWLEY. U. S. Dept. Agr., *Tech. Bull.* 105, 1-20(1929).—A short-cut method is given for calcg. the nutritive value of diets. It usually gives values within 5% of those obtained by the long method and requires only about 42% as much time.

A. L. MEHRING

**Vitamin content of silo juices.** FRITZ DUSCHEK. *J. Landw.* 76, 197-216(1928).—The vitamin content of serradella silage juice was shown, by the betterment of health conditions and increases in live wt. of rats previously fed on vitamin-deficient diet. Under like conditions no beneficial results were observed in growth and development with freshly pressed juice from maize and red clover silage but there was an improvement in health conditions. These effects were not produced with juices from cold-pressed silos. In elec. ensilage practice losses of valuable food material can be prevented by mixing the juices with absorbent material for subsequent feeding purposes.

The story of carbonated beverages. Composition and value (STORMS) 12.

## G—PATHOLOGY

H. GIDEON WELLS

**Chemistry of nephritis with uremia.** P. CRISTOL. *Arch. soc. sci. méd.* 9, 126-67 (1928); *Physiol. Abstracts* 13, 457.—In the investigation of deficiency and renal function it is essential to start with a table of correct proportions of all normal constituents of the blood. Non-protein N varies greatly with the method of dealbumination employed; it is of great importance to have a uniform technic for this, and the best reagent for the purpose is trichloroacetic acid. The coeff. urea N/total N in uremia is high. Urea is the constituent, the retention of which is absolutely and relatively highest. Residual N is the total nonprotein N less urea N. It is better to det. separately each constituent which contributes to it—uric acid, creatinine, etc.—than to consider residual N as a whole. Indoxyl is an important constituent to det. in blood as a mark of renal deficiency; how far the kidney is responsible for changes found in the various constituents of the blood is to be detd. by such criteria as urea concn. in urine, secretory constants, and elimination of methylene blue.

H. L. D.

**Metabolism in heart disease.** D. LASZLO. *Klin. Wochschr.* 7, 1411-5 (1928); *Physiol. Abstracts* 13, 512.—In cases of uncompensated heart disease during rest the N/P ratio in the urine is lower than in the food, indicating a disproportionate loss of P. Administration of Na phosphate for a few days leads to a retention of P. (It is not stated whether the fecal excretion was detd.) The skeletal muscle of persons who have died from heart disease is poorer in P than normal muscle, and the same is true, but to a lesser extent, for heart muscle. The creatinine and uric acid excretion is increased, and the amt. of these substances in the blood is also above normal. After mild exercise the P, uric acid and creatinine excretion are increased. In the blood the creatinine and uric acid increase, whereas the P diminishes. Blood lactic acid also rises above the normal value, and takes an hour to return to the resting level.

H. L. D.

**Coloring matters in functional liver tests.** H. J. D'AMATO. *Semana méd.* (Buenos Aires) 35, 1505-20 (1928); *Physiol. Abstracts* 13, 520.—Methylene blue, indigo carmine, Congo red, neutral red, sulfophenolphthalein, phenotetrachlorophthalein, bromosulfophthalein, phenoltetraiodophthalein and rose bengal have all been used as tests for liver function. Bromosulfophthalein and rose bengal give the best results. H. L. D.

**The relation between cancer and lipid metabolism.** F. BURGHEIM. *Klin. Wochschr.* 8, 828-30 (1929).—Treatment of cancer patients with x-rays leads to a transitory rise in the cholesterol content of the blood. This is not the case with normal individuals, and it is not true of cancer patients that have had the tumor removed by operation. Malignant tumors contain more cholesterol than do benign tumors. The possible relationship between cancer and cholesterol is discussed. MILTON HANKE

**Echinococcus antigen.** JOHANN H. BOTTERI. *Klin. Wochschr.* 8, 836-9 (1929).—A protein-free fluid was obtained from one spleen hydatid. This material was used as antigen in expts. on human beings. This antigen, injected subcutaneously, leads to sensitization of the skin so that a wheal is obtained upon intracutaneous reinjection. Anaphylactic phenomena are not observed when this antigen is injected intravenously into sensitized humans. Injection of fluid from a protein-contg. hydatid gives rise, in a sensitized person, to a wheal (primary reaction) and a deep edema (secondary reaction). The protein-free hydatid fluid produces only the primary reaction. This type of reaction may be due to polypeptides. The secondary reaction is a true protein allergy.

MILTON HANKE

**The action of fluoride on cell metabolism.** WILHELM EWIG. *Klin. Wochschr.* 8, 839-40 (1929).—The fluoride ion has little, if any, action on the O consumption of cells; but it markedly reduces anaerobic glycolysis of all cells. The latter action is particularly striking in the case of cancer cells.

MILTON HANKE

**Antibody formation in experimental syphilis.** ALFRED COHN. *Klin. Wochschr.* 8, 886 (1929).—The injection of dead *Spirocheta pallida* into rabbits, or man, engenders antibodies that appear in the serum. Such sera render spirochetes inactive and lead to their agglutination. No explanation is offered for the fact that such antibodies do not seem to appear in patients afflicted with syphilis.

MILTON HANKE

**The excretion of methylene blue (methylthionine chloride, U. S. P.) by the biliary**

system of the rabbit. Its significance for the conception of hepatogenous stasis in the gall bladder. B. HALPERT AND M. T. HANKE. *Arch. Path.* 7, 473-7(1929).—Expts. with methylene blue on rabbits furnish substantial evidence that the bile does not, under ordinary conditions, leave the gall bladder through the cystic duct. They furnish a striking example of stasis in the gall bladder for which the liver is responsible (hepatogenous stasis). In view of the possibility of creating conditions analogous to those described here for methylene blue, but with agents with more pronounced bactericidal action, they may indicate the road leading to successful chemotherapy of the gall bladder.

HARRIET F. HOLMES

Anaphylaxis in the white rat as influenced by diet. B. C. SEEGAL AND D. KHORAZO. *Arch. Path.* 7, 827-34(1929).—Pronounced symptoms of anaphylactic shock cannot be produced in white rats on a diet of oats, bread, milk and greens. Symptoms of anaphylactic shock can be constantly produced in white rats on a diet of white bread and H<sub>2</sub>O. The suprarenal glands of rats on a diet of bread and H<sub>2</sub>O are considerably smaller than those of animals on a complete diet as far as investigated. The titer of the precipitin and the titer of the precipitinogen content of the serum of sensitized rats on a diet of bread and H<sub>2</sub>O do not differ significantly from the corresponding titers of the serum of sensitized animals on a diet of oats, greens, bread and milk.

H. F. H.

Gastric secretion and its relationship to the urinary reaction. D. T. DAVIES. *Brit. J. Exptl. Path.* 10, 1-9(1929).—A normal secretion of gastric HCl is followed by a definite alk. tide in the urine. In cases of true achlorhydria the reaction of the urine is remarkably const., and it may afford an addnl. means of diagnosis in conditions where achlorhydria is the rule. It also affords a distinction between true and false achlorhydria, a method less fatiguing than the estn. of the total and mineral chlorides of the gastric secretion. An acid tide may be obtained in cases in which there is rapid evacuation of stomach contents and early stimulation of alk. pancreatic juice.

HARRIET F. HOLMES

Blood phosphorus in health and disease. IV. The phosphorus content of the blood in diabetes mellitus. F. B. BYROM. *Brit. J. Exptl. Path.* 10, 10-15(1929); cf. C. A. 22, 3209.—In severe untreated diabetes and in diabetic coma there is a pronounced fall in the org.-acid-sol. P ("ester P") of the blood corpuscles, which appears to be the results of acidosis. After satisfactory treatment by dietetic restriction and insulin, the ester P returns to the normal level. In mild diabetes and in cases of moderate intensity the only abnormality is a small increase in the ester P content of the corpuscles. In fatal diabetic coma the inorg. phosphate rises very considerably, probably as the result of renal damage. The conclusions of Bloor (C. A. 10, 3105) with regard to the lipin content of the blood in this disease are confirmed. There is an increase in the plasma lipin P in many cases of severe diabetes, the amt. of lipin in the corpuscles remaining, as in nephritis, relatively normal. The lipin P in diabetes differs in its reaction to treatment. Whereas the inorg. and ester P are restored to normal after treatment, the lipin frequently remains unchanged or is even increased. This is possibly due to the fact that the av. diabetic diet usually includes appreciably more fat than that of the normal individual or the untreated diabetic.

H. F. H.

The glucolytic action of some tumors and the effect of insulin. S. L. BAKER, F. DICKENS AND E. J. CALLIMORE. *Brit. J. Exptl. Path.* 10, 19-26(1929).—Expts. have shown a marked difference between certain normal tissues and malignant tumors as regards the anaerobic metabolism of glucose. This is in agreement with the work of Warburg (*Biochem. Z.* 160, 307(1925); cf. C. A. 20, 2364). Tumor tissues produced about 5 to 10 times as much lactic acid as was produced by normal tissues under the same conditions. The amt. of lactic acid produced was nearly equal to the amt. of glucose destroyed. The addn. of either insulin or thyroxine produced no demonstrable effect upon the glucose metabolism.

HARRIET F. HOLMES

A method for early serodiagnosis of cancer by use of the Botelho reaction. K. ITCHIKAWA. *Neoplasmes* 7, 326-31(1928).—Certain modifications increase the reliability of the Botelho reaction for the diagnosis of cancer. The percentage of serum albumin and serum globulin in the serum is calcd. by use of the refractometer and viscometer. When the Botelho reaction is pos. while the serum contains a greater percentage of albumin than normal serum, the results are definitely pos. for cancer. If, however, the Botelho reaction is neg. repeat the reaction, reducing the percentage of serum albumin to the normal. A pos. reaction indicates definitely cancer and a neg. reaction noncancer. When the Botelho reaction is neg. while the serum contains a percentage of globulin higher than normal, the results are definitely neg. for cancer. If, however, the Botelho reaction is pos. the result is not definitely pos. for cancer (certain cases of tuberculosis give a pos. Botelho reaction). The reaction is to be

repeated, the albumin being adjusted to the same percentage as in normal serum but with the addn. to the percentage of the albumin in the serum to be examd. of  $\frac{2}{3}$  of the difference between the percentage of the globulin of the serum; this is to be considered as albumin. A pos. reaction now definitely indicates cancer and a neg. reaction, noncancer.

HARRIET F. HOLMES

**The influence of diet in cancer.** M. GUEIRN. *Neoplasmes* 8, 5-41 (1929).—A general review with 117 references. From the point of view of prophylaxis a moderate diet is advised, rich in vitamin A and Mg salts with a restricted use of foods rich in vitamin B and the lipoids, especially cholesterol and its ethers.

HARRIET F. HOLMES

**Diabetic albuminuria—the so-called chronic nephrosis.** ALBERT A. EPSTEIN. *Arch. Verdauungskrankh.* 44, 31-55 (1928).—Discussion.

FRANCES KRASNOW

**New contributions to gastric chromoscopy; the combined gastric function test.** R. A. LURIA AND E. R. MOGILEVSKII. *Arch. Verdauungskrankh.* 44, 55-79 (1928).—The combined gastric function test (the simultaneous study of the acidity curve and chromoscopy) offers a possibility for more detailed information of the secretory function. Generally the neutral red elimination runs parallel to acidity content in that it is accelerated during hyperacidity, decreased during hypoacidity and ceases during anacidity. Chromoscopy helps to det. the source of mucus in gastritis, to differentiate the cases of gastritis due to acidity disturbances from myxorrhoea of vegetative origin and to classify the different types of achylia.

FRANCES KRASNOW

**Anacidity, pseudoanacidity and histamine reaction.** J. VANDORFY. *Arch. Verdauungskrankh.* 44, 176-82 (1928).—The histamine test is valuable in certain cases of anacidity for diagnosis as well as in the detn. of the duration of illness.

F. K.

**Production of specific hemoglobin precipitin.** A. D. GUSSEV. *Deut. Z. ges. gericht. Med.* 13, 270-7 (1929).—Immunization with erythrocyte ext. does not produce strongly specific serum but a serum precipitin and hemoglobin precipitin. Injection of hemoglobin solns. produces highly specific hemoglobin precipitin.

F. K.

**Some of the physicochemical properties of the virus of hog cholera.** H. C. H. KERNKAMP. *J. Am. Vet. Med. Assoc.* 74, 844-63 (1929).—Hog cholera virus is not retained by the plaster of Paris-magnesium oxide filters of Kramer. The virus passed the ultra-filter when 2% collodion membranes were used. It seems that the size of the virus particles is less than 35  $\mu$ .

FRANCES KRASNOW

**Suprarenal insufficiency. II. The relative importance of cortex and medulla in the susceptibility to histamine of suprarenalectomized rats.** L. C. WYMAN. *Am. J. Physiol.* 87, 29-41 (1928).—After removal of both adrenals rats were very much more susceptible to histamine poisoning. The protective action of the adrenal against histamine seems to be furnished by the medullary rather than the cortical tissue. **III. The effect of thyroidectomy and of forcing fluid on suprarenal insufficiency in rats.** *Ibid* 42-50.—The expts. indicate that in the rat dehydration of the blood and tissues is not a factor in subacute and chronic suprarenal insufficiency and the attendant increased susceptibility to intoxication.

J. F. LYMAN

**The utilization of acetoacetic acid by normal and diabetic dogs before and after evisceration.** I. L. CHAIKOFF AND S. SOSKIN. *Am. J. Physiol.* 87, 53-72 (1928).—Muscles of depancreatized dogs utilized acetoacetic acid as rapidly as normal animals. Insulin cannot exert its antiketogenic effect by influencing the rate of utilization of acetoacetic acid. It is suggested that the ketone bodies are formed in the excessive conversion of fat to carbohydrate and that this process is inhibited by insulin.

J. F. LYMAN

**The role of toxins in parathyroid tetany. II. Tissue changes in parathyroid tetany and in guanidine poisoning.** L. A. ELKOURIE AND E. LARSON. *Am. J. Physiol.* 87, 124-30 (1928).—A microscopic comparison of tissues of animals dying of parathyroid tetany with those of others poisoned with guanidine showed quite dissimilar conditions.

J. F. LYMAN

**Metabolism of total base in nephritis.** GLADYS L. BOYD, ANGELA M. COURTNEY AND IDA F. MACLACHLAN. *Am. J. Diseases Children* 36, 16-21 (1929).—The concn. of base in the blood plasma during nephritis varies but little from the normal. Values slightly lower than normal may be assoc. with a renal acidosis together with an increase in the blood phosphate concn., with the end state in chronic interstitial nephritis, or with a positive retention of Na and Cl. The amt. of base in the plasma does not appear to be detd. by the degree of diln. of the blood or the degree of retention of N and bases other than Na. Less base is excreted with the urine during nephritis, and more with the feces.

E. R. MAIN

**The basal metabolism in gynecology. I. The basal metabolism during the various phases of the menstrual cycle and in different forms of ovarian insufficiency.**

G. DELLEPIANE. *Boll. soc. ital. biol. sper.* 4, 110-4(1929).—In normal women the basal metabolism during the various phases of the menstrual cycle oscillated only about 10% from the normal. The basal metabolism of women suffering from ovarian insufficiency and of those rendered sterile by exposure to Röntgen rays or by surgical operations was practically normal. II. The basal metabolism in benignant and malignant neoplasia of the genital system. *Ibid* 115-8.—The increase in the basal metabolism of women suffering from fibromyoma of the uterus was not const.; it varied from 6 to 21% in about one-half the cases. Surgical removal of the tumor produced only a slight decrease. Malignant and benignant tumors of the ovaries did not change the basal metabolism in any const. manner.

PETER MASUCCI

Disturbances of the metabolism of sulfur and their influence on chronic rheumatism. P. CAWADIAS. *Ann. med.* No. 3(1928); *Rev. sud-americana endocrinol. immunol. quimioterap.* 11, 749-53(1928).

A. E. MEYER

Basal metabolism in polycythemia vera. THEODORE L. BLISS. *Ann. Internal Med.* 2, 1155-61(1929).—In 23 cases of polycythemia vera, there was an increase in the basal metabolic rate of 10% above the normal range. There is frequently an increased production of heat, the cause of which is unknown.

JOHN T. MYERS

Vasopressor substances in the liver after obstruction of the common duct. I. S. RAVDIN. *Arch. Surgery* 18, 2191-201(1929).—There is an increase of both histamine and choline in the liver following common duct obstruction. This may account for the so-called liver shock after operations for the release of common duct obstructions.

JOHN T. MYERS

Investigation of complement. III. The addition of ammonium salts to guinea pig serum. H. TOKUNAGA. *Centr. Bakt. Parasitenk.*, I Abt., 111, 470-8(1929); cf. *C. A.* 22, 3217. IV. The action of ammonium sulfate on complement. *Ibid* 478-83.—Treatment with  $(\text{NH}_4)_2\text{SO}_4$  completely inactivated complement, the rate increasing with the temp. Diln. of the serum hastens inactivation. Too much  $(\text{NH}_4)_2\text{SO}_4$  fails to inactivate.

JOHN T. MYERS

The conservation of serum. K. L. WOLTERS. *Centr. Bakt. Parasitenk.*, I Abt., 111, 483-91(1929).—Therapeutic immune sera may be safely and quite permanently preserved by the addn. of 0.1% of quinosol, and diagnostic sera with 0.5%. Chlorophenol (0.25%) or  $\text{HgCl}_2$  (1 : 5000) can be used.

JOHN T. MYERS

Comparisons of native and heated immunogens of the cholera vibrio with special reference to toxicity and antigenic power. R. TORIKATA AND O. UYEDA. *Centr. Bakt. Parasitenk.*, I Abt., 112, 91-108(1929).—Heated "immunogens" have a greater antigenic power than unheated, as regards the production of agglutinins, precipitins and bacteriolysins. Heating decreases toxicity.

JOHN T. MYERS

Recent studies on blood groups. MAX BERLINER. *Folia Haematol.* 38, 52-85(1929).—This is a review of the biol. and chem. concepts in this field with a bibliography of 352 titles.

JOHN T. MYERS

Immune reactions and cancer. F. C. PYBUS AND H. R. WHITEHEAD. *J. Path. Bact.* 32, 195-202(1929).—The serum of rabbits immunized against mouse carcinoma has a harmful effect on mouse carcinoma, and normal heart and kidney growing *in vitro*. There is no marked specificity for the carcinoma. There is no evidence of the existence of antibodies common to the malignant cells of different animal species.

JOHN T. MYERS

Observations on the metabolism of amino acids in health and disease. LESLIE WIRTS. *Quart. J. Med.* 22, 477-91(1929).—The fasting amino N of the blood is maintained at a level of 5.4 to 7.4 mg. % with remarkable constancy in health and disease. After the ingestion of protein or amino acids, the amino N of the blood rises to a peak in 2 hrs. and falls to normal in 6 to 8 hrs. With the largest dose of amino acid possible, the blood does not exceed 15-20 mg. %, the bulk being taken up by the tissues. The blood urea also rises, the peak being reached in 2-4 hrs. with an increase of about 50% over the fasting level. The fasting and post-absorptive amino N is normal in diseases of the liver, with the exception of acute yellow atrophy where cell necrosis and autolysis may cause an increase. Liver diseases do not affect blood urea. In diabetes, the blood urea may fail to rise to the normal extent following ingestion of amino acids. This is not the result of temporary disorder of the liver as it persists over a period of months. It is not entirely remedied by insulin. A similar subnormal increase of urea may occur in disorders which do not affect the liver. Hence amino acid detns. are of no value in the diagnosis of hepatic disease.

J. T. M.

The specific oxygen capacity of the blood coloring matter in pathological conditions. H. ENGELKES. *Quart. J. Med.* 22, 507-17(1929).—The normal S. O. C. (specific O capacity) of hemoglobin is 401 cc. of O under standard conditions per g. of Fe. In 3

cases of autotoxic intraglobular thiohemoglobinemia the "S. O. C." was less than 401. In cases of secondary anemia it was unchanged. In hemolytic anemia, as malaria and pernicious anemia, there is a drop during periods of blood destruction. In malaria the drop is probably due to an intraglobular hematinemia. In pernicious anemia the cause of the drop could not be demonstrated spectroscopically. JOHN T. MYERS

## H—PHARMACOLOGY

A. N. RICHARDS

The effect of  $\beta$ -tetrahydronaphthylamine on the body temperature of rabbits in which heat regulation has been disturbed by the cold puncture or the extirpation of the corpus striatum and thalamus. WATARU TAKAHASHI. *Tôhoku J. Exptl. Med.* 12, 397-405(1929).— $\beta$ -Tetrahydronaphthylamine-HCl causes an increase of body temp. B. C. BRUNSTETTER

Nasal turbidity in man following administration of nitroglycerin. DUNCAN C. WALTON AND EDW. F. KEHR. *Arch. intern. pharmacodynamie* 35, 28-45(1928).

DAVID DAVIDSON

Saponins and digitalis. The influence of saponins on the power of diffusion through and of fixation in a living membrane of digitoxin and bigitaligenin. EDOUARD FROMMEL. *Arch. intern. pharmacodynamie* 35, 46-62(1928).—The saponins shorten the 3 periods of the pharmacodynamic action of digitoxin on the heart of a frog and thus seem to reinforce its power. The arrest is irreversible like that of digitoxin itself. Their action on bigitaligenin is not const.; sometimes they have a neutral action and sometimes a reinforcing action. Like that of bigitaligenin itself, the arrest is always reversible. The saponins lower the threshold of cellular permeability (measured by the dialysis through the living skin of a frog) for digitoxin and bigitaligenin, and allow a rapid penetration of active principle of digitalis. The saponins do not appear to effect the partially reversible physicochem. combination between digitoxin and protoplasm nor the reversible fixation of bigitaligenin to the cell.

DAVID DAVIDSON

Hyperthermic and cardiovascular action of dinitro- $\alpha$ -naphthol in the dog. C. HEYMANS AND JEAN J. BOUCKAERT. *Arch. intern. pharmacodynamie* 35, 63-9(1928).—The intravenous injection into dogs of dinitro- $\alpha$ -naphthol (I) in the dose of 1.33-5.5 cg. per kg. with or without anesthesia causes an increase in temp. to as high as 44.3° without convulsions. I maintains or even augments the temp. of anesthetized dogs whose cervical cord has been cut. I is a peripheral vasodilator but this action is rapidly compensated in the animal by the stimulating action of I on the vasomotor center. Strong doses of I cause systolic arrest of the heart. The hyperthermy is accompanied by hyperglucemia. I is not hemolytic and does not cause edema of the lungs; it does not cause a rise in temp. in the rabbit.

DAVID DAVIDSON

Influence of tetrahydronaphthylamine on the temperature and respiratory exchange—antagonistic action of chloralose and antipyrine. P. REGNIERS. *Arch. intern. pharmacodynamie* 35, 70-83(1928).—Tetrahydronaphthylamine (I) given intravenously in a dose of 1-3 cg. per kg. causes the following phenomena in the dog: excitement, mydriasis, vasoconstriction, salivation, erection of hair and rise of temp. to 43.5°. The respired vol. of air is quadrupled and the CO<sub>2</sub> elimination increased. Chloralose depresses these phenomena. Antipyrine given intravenously in doses of 7 cg. per kg. does not hinder the action of I; in doses of 15-20 cg. per kg. it partially inhibits the effect on temp. and on respiration.

DAVID DAVIDSON

Electrocardiographic changes from cocaine, procaine and butyn. M. L. TANTER, W. DOCK AND N. S. BROWN. *Arch. intern. pharmacodynamie* 35, 102-12(1928).—"Cocaine and butyn, in toxic, subfatal and fatal doses cause changes in the rat, either tradycardia or tachycardia, depress the intracardiac conduction system and irritate the muscle of the ventricle, independent of the autonomic innervation, the effects being characterized by considerable irregularity. Procaine over a considerable range of dosages has relatively little effect on the heart; but the effects of very large toxic doses resemble those of cocaine and butyn. Very small doses of cocaine which can sensitize to adrenaline and desensitize to tyramine and ephedrine on blood pressure cause no demonstrable electrical or other changes on the heart, thus relegating the seat of these peculiar drugs to the blood vessels."

DAVID DAVIDSON

The influence of the alcohols upon the cholagog action of bile salts. ERNST PROKOP. *Z. ges. exptl. Med.* 58, 330-9(1928).—Using urethanized rabbits P. injected the following bile salts intravenously and detd. the cholagog action with a bile fistula; Na cholate, Na dehydrocholate, Na desoxycholate, Na apocholate, and Na biliate. The av. increases in bile flow were, resp., 110, 45, 100, 230 and 0%. Following adminis-

tration of EtOH by mouth prior to the injection of the bile salts, the increases in bile flow were, resp., 46, 89, 92, 53 and 0%, and following amyl alc. the increases were 31, 70, 0, 33 and 0% over the normal flow rates. P. suggests that the bile acids act directly on the liver and that the action of EtOH and amyl alc. is analogous to that of  $\text{CHCl}_3$  on the liver.

F. L. DUNN

The recovery phase following ammonium chloride and diabetic acidosis. FRITZ MAINZER AND ANNA JOFFE. *Z. ges. expil. Med.* 59, 492-508(1928).—M. and J. studied the variations in blood  $\text{CO}_2$ , Cl,  $p_{\text{H}}$ , total base and inorg. P in man following the administration of 5 g.  $\text{NH}_4\text{Cl}$  daily. The diet and water intake were kept const. and the Cl in the urine was detd. The rise in the blood bicarbonate during the recovery phases depends in part upon a lowering of the blood Cl. This may result in an alkalosis due to an acid deficit. The  $p_{\text{H}}$  of the blood returns to normal before the blood bicarbonate as in diabetic acidosis. In the regulation of the blood reaction by respiration the rate of development of disturbances in acid-base balance is of importance as well as the measurement of the amount of disturbance. The quant. consideration of the blood mineral analyses leads M. and J. to suggest that variations in blood concn. and diln. lead to changes in the alkali-binding capacity of the proteins. A bibliography is included.

F. L. DUNN

The regulation of the hydrogen-ion concentration of the blood. III. Experimental studies on the action of strychnine upon the acid-base balance of the blood. SCHAU-KUANG LIU AND R. KRUGER. *Z. ges. expil. Med.* 61, 757-66(1928).—Strychnine had no specific action upon the respiratory center. Small doses frequently raised the blood  $p_{\text{H}}$ . Large doses produced an acidosis, the animal dying quickly. Chloral hydrate reduced the acidosis and the convulsions. The importance of the acidosis in producing the death of the animals was not detd. Bibliography. IV. The action of strychnine on the blood. *Ibid* 767-74.—Strychnine accelerates the reduction of hemoglobin and inhibits its oxidation. A lactic acid soln. with a  $p_{\text{H}}$  of 1.97 has an action on hemoglobin similar to that of strychnine. This action is due to a chem. reaction between strychnine and hemoglobin. Strychnine produces an acidosis by increasing general metabolism, reduction in O content of blood, and direct action on hemoglobin. Bibliography. V. Further observations on the nervous regulation of the hydrogen-ion concentration of the blood. *Ibid* 775-9.—Following bilateral cervical sympathetic or unilateral vagus section in rabbits there is no change in the blood  $p_{\text{H}}$ . From 2 to 3 hrs. after bilateral vagus section the blood  $p_{\text{H}}$  drops. The lowering parallels the failure of the heart and circulation, and with it, the respiration. VI. The action of synthalin upon the acid-base balance of the blood. *Ibid* 780-6.—Synthalin has an insulin-like action but a delayed one. Small intravenous injections often raise the blood  $p_{\text{H}}$  but subcutaneous or intramuscular injections have no effect. Large intravenous doses produce convulsions and lowering of the blood  $p_{\text{H}}$ . Bibliography. VII. The respiratory regulations of the hydrogen-ion concentration of the blood. *Ibid* 787-93.—Injection of small quantities of lactic acid or NaOH produces only momentary changes in the blood  $p_{\text{H}}$ . Injection of distd. water produces no effect. Bibliography. VIII. The action of acids, bases and other toxic material upon the acid-base balance of the blood. SCHAU-KUANG LIU. *Ibid* 794-807.—Conclusions. Bibliography.

F. L. DUNN

Studies on the water economy. II. The action of hypophysis extracts upon salt diuresis. KL. GOLLWITZER-MEIER AND W. BROCKER. *Z. ges. expil. Med.* 62, 97-104(1928).—Under the influence of hypophysis exts. and withholding of water the percentage excretion of Na, K, Cl and P is increased in the urine and the absolute quantity of Na and Cl is increased but that of K and P is decreased. III. The diuretic action of thyroxine. *Ibid* 105-13.—Studies in man show that thyroxine with forced fluids affects the exchange between blood and tissue. There results a streaming of a fluid rich in Na and Cl and relatively poor in K, P and Ca from the tissues into the blood, resulting in a slight lowering or a sharp elevation of Na and Cl with a sharp drop in K and P. The hydreemia was not so marked with thyroxine as it was when only water was given. The amount of Na and Cl in the urine was increased while that of K and P was not changed. G. and B. suggest that the salt mobilization and excretion appear to be the significant changes following thyroxine administration.

F. L. DUNN

Studies with secretin. IV. The influence of secretin upon bile secretion and diabetic acidosis. LADISLAUS TAKACS. *Z. ges. expil. Med.* 62, 114-7(1928); cf. C. A. 22, 2787; 23, 623.—T. found no increase in bile secretion following the administration of secretin contrary to the observation of previous workers. Large doses result in some secretion which T. considers due to the protein content. Secretin lowered the blood sugar and acetone in diabetes mellitus with acidosis.

F. L. DUNN

Insulin substitutes. V. Hypoglucemic substances in cereals and legumes.

F. KAUFMANN. *Z. ges. expth. Med.* 62, 147-53(1928); cf. *C. A.* 23, 436.—Peroral feedings of exts. of the legumes, peas, lentils, beans, and the cereals, oats, rye and wheat to rabbits showed a lowering of the blood sugar beginning in 2-3 hrs. and reaching a max. in 6-8 hrs. Intravenous injections produced more prompt lowerings. K. suggests that the success of oatmeal cures and starch diets in diabetes might be due to the presence of hypoglucemic substances. VI. Experimental studies of the action of the cereal cures in diabetes. *Ibid* 154-9.—The effectiveness of the exts. in lowering blood sugar in rabbits that have received 2 g. per kg. dextrose by mouth is in the following descending order: oats, beans, peas, lentils, wheat and rye. VII. The action of jambul bark extract. *Ibid* 160-4.—The jambul bark ext. has an effect upon glycogenolysis and glycogen storage in exptl. animals. The toxicity of the ext. depends upon the amount of stored glycogen. The lowering of blood sugar in well-fed exptl. animals may not be analogous to that in diabetes in which high blood sugars are associated with low glycogen stores but may correspond to the expt. in which the animals are glycogen-starved and a temporary hyperglucemia is produced by intravenous injections of glucose. The few available results do not indicate that jambul exts. are of much value in diabetes.

F. L. DUNN

The pharmacology of cerebral vessels. M. MUVA, M. OSAKI AND R. SPIROSHITA. *Arch. expth. Path. Pharmacol.* 128, 211-24(1928); *Physiol. Abstracts* 13, 479.—Pituitary and strophanthin produce vasoconstriction, and antipyrine and salicylic acid vasodilatation.

H. L. D.

Experiments with sparteine. W. BURRIDGE AND D. N. SETHI. *Arch. intern. pharmacodynamie* 34, 195-203(1928); *Physiol. Abstracts* 13, 475.—Sparteine exerts independent actions of augmentation and depression on the heart. Augmentation predominates when the drug is used in diln.; depression predominates when the drug is used in great concn.

H. L. D.

Isopropyl alcohol. U. G. BIJLSMA. *Arch. intern. pharmacodynamie* 34, 204-13(1928); *Physiol. Abstracts* 13, 475.—The use of isopropyl alc. as a substitute for EtOH is common in cosmetics, mouth washes, etc., and the question has arisen whether the procedure is harmless or not. Both alcs. have qualitatively the same effect on man and animals. Quantitatively the isopropyl alc. is 2.4 times stronger than EtOH for the same mol. concn. In some female rabbits hematuria occurred with each. The effects of drops in the eyes were the same for both alcs. Local and general toxic effects were similar, the latter being quantitatively somewhat greater with isopropyl alc. It follows that the use of isopropyl alc. in mouth washes and for outward application need cause no concern.

H. L. D.

Hypoglucemic action of colloidal sulfur. G. PENNETTI. *Arch. intern. pharmacodynamie* 34, 214-23(1928).

H. L. D.

The action of solanum pseudocapsicum on the circulatory system. J. M. WATT, H. L. HEIMANN AND E. MELTZER. *J. Med. Assoc. S. Africa* 11, 298(1928); *Physiol. Abstracts* 13, 475-6.—An ext. of the leaf of this plant produces a profound effect on the circulatory system. The leaf contains an alkaloid or alkaloids, but these have not yet been isolated in a pure form. An impure alkaloidal product produced the same effects as the ext.

H. L. D.

Electrocardiographic investigation of the action of insulin on the heart. III. Insulin and the damaged heart muscle. E. v. HAYNAL, L. VIDOVSKY AND G. GYÖRGYI. *Klin. Wochschr.* 7, 1543-9(1928); *Physiol. Abstracts* 13, 511.—An electrocardiographic investigation of the action of insulin on the heart, embracing 33 cases of heart disease of various kinds. In 14 of the cases insulin produced only alterations in the form of the electrocardiogram; in the other 19 changes of rhythm or cond., or both, were observed. The disturbances of rhythm occurred during the hypoglucemic phase, and were resolved by intravenous injection of glucose. They occurred principally in patients with myocardial disease. The authors recommend a high carbohydrate level along with insulin in all diabetics with diseased myocardium, and the injection of glucose along with insulin in all cases of diabetic coma with cardiovascular symptoms.

H. L. D.

Influence of the nervous system on glucemia. II. Effect of sympatho- and parasympatho-mimetic drugs on blood sugar. L. LA GRUTTA. *Rivista patol. sper.* 3, 206-21(1928); *Physiol. Abstracts* 13, 590.—Injection of adrenaline, pilocarpine, and atropine separately produces hyperglucemia in dogs. Muscarine produces slight hyperglucemia, and ergotamine some hypoglucemia. Injected together, adrenaline and pilocarpine, adrenaline and muscarine, adrenaline and atropine produce hyperglucemia; atropine and ergotamine produce some hypoglucemia; and pilocarpine and ergotamine produce some hyperglucemia.

H. L. D.

The supposed neutralization of insulin by blood. G. CAIZZONE. *Rivista patol. sper.* 3, 243-5(1928); *Physiol. Abstracts* 13, 589.—Injection of blood corpuscles produces hyperglucemia, which masks the effect of insulin when the 2 are mixed and injected together. H. L. D.

Insulin sensitiveness of man. K. CSÉPAI AND Z. ERNST. *Wien. klin. Wochschr.* 41, 25-6(1928). H. L. D.

Comparison of the oxytocic, pressor and antidiuretic activities of commercial samples of pituitary extract. U. G. BIJLSMA, J. H. BURN AND J. H. GADDUM. *Quart. J. Pharm.* 1, 493-508(1928).—Four com. exts. of the posterior lobe of the pituitary have been estd. in comparison with the international standard for their oxytocic and pressor power by 3 independent workers. One worker has also tested their antidiuretic power on the unanesthetized dog and another has devised a new method of testing for this action on a normal human being. This method is now described. The results obtained by different workers agree with one another, except that there are differences of opinion as to both the pressor and oxytocic powers of one of the exts. and as to the antidiuretic power of another. It is shown that the antidiuretic effect is not due either to the pressor or to the oxytocic principle. The test for any one of these 3 active principles does not provide a reliable index of the concn. of any other of them in com. exts. The present international standard can only be used as a standard for antidiuretic activity if it is found that different preps. of it contain the same concn. of the antidiuretic principle. W. O. EMERY

Action of drugs on the kidney. E. B. VERNEY. *Quart. J. Pharm.* 1, 546-57(1928).—An attempt has been made to classify drugs with diuretic action into groups, the activity of each of which can be the most readily interpreted in terms of one of the present theories of urinary secretion. In this connection a theory of urinary secretion is delineated. W. O. EMERY

Effect of pituitary extract and adrenaline on ketonuria and liver glycogen. J. H. BURN AND H. W. LING. *Quart. J. Pharm. and Pharmacol.* 2, 1-16(1929); cf. C. A. 22, 3700.—Injections of pituitary ext. reduce the amt. of the ketonuria seen in the spring months when rats are given a diet of butter fat; they also cause the disappearance of glycogen from the liver during the 1st 5 days of fat diet. Injections of adrenaline have various effects on the ketonuria. They may lessen it; they may leave it unchanged; or they may increase it. Anderson and Anderson have previously described the augmentor effect and the present writers have confirmed it, but have not been able to reproduce it with sufficient regularity to investigate its nature. Injections of adrenaline do not seriously affect the rise in liver glycogen, but may reduce its amt. below the normal on the 2nd and 3rd days of the fat diet. When they do, they increase the ketonuria coincidentally. The rise of liver glycogen in the spring months occurs at just as great a rate as in the winter; hence the greater ketonuria in the spring than in the winter months is not connected with the amt. of liver glycogen. W. O. EMERY

Occupational lead poisoning. B. CHAIKES AND C. LEWIN. *Med. Klin* 24, 848-51(1928); *U. S. Pub. Health Eng. Abstracts* E-789c, 6.—A total of 1560 Pb workers have been examnd. at the Berlin-Lankirtz medical center. Org. changes in the blood, kidneys, nervous system, intestinal canal and liver can rightly be attributed to the action of Pb, if as the result of a complete examn. it is shown that the patient had previously suffered from Pb poisoning and, naturally, if signs of this are still present. The diagnosis of Pb poisoning depends mainly on clinical examn.; to base a diagnosis on the presence or absence of the 4 cardinal signs alone is not sufficient. C. R. FELLERS

Lead in the treatment of cancer. H. C. ULLMAN. *Southwestern Med.* 13, 73(1929).—Although it caused marked injury to the blood and kidneys colloidal Pb also had considerable effect on some of the tumors. Insol. Pb phosphate has essentially the same effect on tumors as colloidal-metallic Pb, is much less toxic, has no effect on the kidneys and has little effect on the blood in most instances. The prepn. is stable and apparently does not grow more toxic with age. In many forms of cancer at least, Pb definitely augments the effect of radiation. C. R. FELLERS

Plasmochine in pregnancy. K. V. THAKKAR. *Indian Med. Gaz.* 44, 198(1929).—In pregnancy complicated by malaria, plasmochine is a valuable therapeutic agent. FREDERICK G. GERMUTH

Tattooing of the cornea with chloroplatinic acid solution for leucoma. B. P. BANAJI. *Indian Med. Gaz.* 44, 201(1929).—The application of a 2% soln. of  $H_2PtCl_6$  to the affected surface is of distinct benefit in the treatment of leucoma. Reduction of the Pt salt occurs in about 2 mins. FREDERICK G. GERMUTH

Sionon, a new substitute for sugar. HELMUTH REINWEIN. *Deut. med. Wochschr.*

55, 397-8(1929).—Sionon, a com. prepn. of *d*-sorbitol, is valuable in the treatment of diabetes.

feeding of about 0.5 g. of sucral (a specially prepd. form of  $\text{Fe}_2\text{O}_3$ ) to debilitated and nervous patients, during the course of 10 days, increased the basal metabolic rate in 6 cases of a total of 10.

ARTHUR GROLLMAN

**Hyperthyroidism and sensitivity to insulin.** E. ADLER. *Wien. Arch. inn. Med.* 16, 343-54(1929).—Five insulin units were injected subcutaneously in 8 normal individuals and in 15 cases of hyperthyroidism of different sorts. Blood sugar detns. were made to show the sensitivity to insulin. There was no marked difference in the reaction in the normal cases and in the cases with hyperthyroidism. No definite relation could be made out between the severity of the case and the sensitivity to insulin nor between the stage of the disease and the sensitivity. There was also no definite relation between increase in basal metabolism and sensitivity to insulin. H. F. H.

**Caffeine in thyroid surgery.** CHARLES C. MILLER. *Am. Med.* 35, 30-4(1929).—It is almost impossible to stop a heart under  $\text{CHCl}_3$  anesthesia, if it has been refortified with caffeine. Digitalis does not accomplish this.

FRANCES KRASNOW

**Chronic poisoning by an irritant contained in cooking utensils and tap water.** LEO SPIRO. *Am. Med.* 35, 40-5(1929).—The nature of the irritant is not detd. F. K.

**The thyroid and manganese treatment.** HERBERT W. NOTT. *Am. Med.* 35, 86-9(1929).—Report of a case of epilepsy in a dog, which, after rectal injection of 1 grain of  $\text{KMnO}_4$  in hot water, seemed to show immediate relief. FRANCES KRASNOW

**The effect of hyoscine and morphine on renal function.** ROGER W. BARNES. *Am. Med.* 35, 97-9(1929).—These drugs are not contraindicated in cases of impaired renal function.

FRANCES KRASNOW

**Value of methylene blue-gentian violet 5 per cent in preoperative skin preparation.** KINGLEY ROBERTS. *Ann. Surgery* 89, 183-90(1929).—Good results are claimed.

FRANCES KRASNOW

**Alcohol injection in angina pectoris.** WM. J. MIXTER AND JAMES C. WHITE. *Ann. Surgery* 89, 199-202(1929).—Good results were obtained. FRANCES KRASNOW

**Studies on the venom of a sea serpent.** *Hydrus platurus* of the Pacific Ocean. ERNEST G. NAUCK. *Arch. Schiffs-Tropen Hyg.* 33, 167-70(1929).—The venom is a neurotoxin.

FRANCES KRASNOW

**Influence of soda on activity of the gastric secretory glands.** EUG. BABSKII. *Arch. Verdauungs-Krankh.* 44, 182-94(1928).—Administration of soda during a 16-day period, either by rectum or *per os*, shows no decrease in secretory activity of the gastric glands. There seems to be a tendency toward an increase in salt content.

FRANCES KRASNOW

**Administration of bile-producing substances *per os* and by duodenum.** N. S. ABRASHYEVA. *Arch. Verdauungs-Krankh.* 44, 230-8(1928).—Olive oil, cream-butter and a mixt. of  $\text{MgSO}_4$  and peptone, administered either *per os* or by duodenum, influence alike the secretion of bile into the intestine.

FRANCES KRASNOW

**Urine sugar and blood sugar after abundant glucose feeding.** BARBARA AND JACQUES GOLDBERGER. *Arch. Verdauungs-Krankh.* 44, 315-37(1928).—The blood sugar curve shows a more or less characteristic hyperglucemia during the first 2 hrs. followed by a hypoglucemia. When 100 g. glucose in 400 cc. weak tea is given either to healthy individuals or to sick persons the sugar-regulating mechanism is normal. In cases of liver disorders, there is during the first 3 hrs. a characteristic rise in blood sugar accompanied by marked decrease in diuresis. Following this is a lowered blood sugar curve (not hypoglucemic) accompanied by a very marked diuresis. In non-insulinized diabetics there is a constant relationship between the blood sugar values and the urine sugar values. The increase in sugar elimination is brought about by the abundant urine excretion and produces the picture of "Glucosehyposthenurie."

FRANCES KRASNOW

**Secretory function of the liver, pancreas and stomach after the duodenal administration of magnesium sulfate.** LOUIS HIRSCHBERG. *Arch. Verdauungs-Krankh.* 44, 393-405(1928).—After the duodenal administration of 30 cc.  $\text{MgSO}_4$  (30%) the bile darkened in color and increased in amount. Such treatment also called forth an increase in the pancreatic enzymes as well as rise in the gastric secretion (mucus and acid).

FRANCES KRASNOW

**Studies of the effects of antimony salts. II. The effect of aminostiburea on cases of kala-azar.** E. C. HODGSON, RAM TARAN SEN AND C. DAS. *Indian J. Med.*

**Research 16, 31-4(1928).**—The drug is a valuable addn. to those already discovered for kala-azar treatment. FRANCES KRASNOW

**Gymnema sylvestre in diabetes mellitus.** R. N. CHOPRA, J. P. BOSE AND N. R. CHATTERJEE. *Indian J. Med. Research 16, 115-24(1928).*—The leaves of *Gymnema sylvestre* contain a substance which has a hydrolytic action on cane sugar. There is also an oxidase-like substance which produces glucolysis in a solution containing glucose. When administered subcutaneously to rabbits, the extracts of the leaves or gymnemic acid and its Na salt have no effect on the blood sugar. F. K.

A comparative study of the action of cinchonidine and cinchonine on the heart. R. N. CHOPRA, B. B. DIKSHIT AND J. C. DAVID. *Indian J. Med. Research 16, 125-33(1928).*—Intravenous injections of cinchonidine in animals produce a marked depression of the amplitude of auricular and ventricular contractions accompanied by a fall of blood pressure. Cinchonine produces an apparent stimulation of the auricle and depression of the ventricle. Both cinchonidine and cinchonine temporarily restore the normal rhythm of the heart after it is experimentally made irregular with aconitine. Levo-rotatory cinchonidine is a more powerful depressant than dextro-rotatory cinchonine. FRANCES KRASNOW

The prevalent compounds of antimony in the treatment of kala-azar. III. Aminostiburea: an analysis of the treatment in 52 cases. L. EVERARD NAPIER. *Indian J. Med. Research 16, 141-7(1928); cf. C. A. 23, 2478.*—Aminostiburea is of considerable value. It is of relatively low toxicity to mice and is well tolerated by man. 3.31 g. per 100 lb. body wt. should effect a cure in 91% of the cases. Its special value seems to be in its action on resistant cases. FRANCES KRASNOW

Studies in malaria, with special reference to treatment. IX. Plasmochine in the treatment of malaria. J. A. SINTON AND W. BIRD. *Indian J. Med. Research 16, 159-78(1928).*—Plasmochine was much more effective than quinine in producing a permanent cure in benign tertian malaria. In the treatment of malignant malaria, the latter is more effective. Plasmochine has a narrow margin of safety in the dosage.

X. Quinine-troposan in the treatment of chronic benign tertian malaria. J. A. SINTON, W. BIRD AND W. B. F. ORR. *Ibid 333-9.*—Troposan seems to be a helpful adjuvant to quinine. The relapse rate was less than that usually seen after the cinchona alkaloids or quinine-stovarsol but was greater than after plasmochine. The drug was well tolerated over a period of 3 weeks of continuous treatment but prophylactic measures should always be taken against chance of poisoning. XI. The cinchona alkaloids in the treatment of benign tertian malaria. J. A. SINTON AND W. BIRD. *Ibid 725-46(1929).*—The quinine and alkali treatment seems to be more efficacious than quinine alone. The four crystallizable alkaloids of cinchona bark (quinine, quinidine, cinchonine and cinchonidine) showed almost equal value in preventing relapses. Cinchona febrifuge is equal to other alkaloids in treatment of chronic infections. FRANCES KRASNOW

Action of antimony compounds on the adrenals. R. N. CHOPRA, J. C. GUPTA AND S. G. CHOUDHURY. *Indian J. Med. Research 16, 441-6(1928)*—Expts. on Belgian hares show that after intravenous administration of org. Sb compds., there is a definite increase in adrenaline content of the gland. After 10 injections the content is nearly doubled. FRANCES KRASNOW

The action of insulin on the free muscle sugar of the normal and diabetic heart. E. W. H. CRUICKSHANK AND SHEONATH PRASAD. *Indian J. Med. Research 16, 473-7(1928).*—The addn. of insulin to the normal heart reduces the free sugar. When the diabetic heart is treated with normal blood which contains insulin the effect in reducing the sugar is greater than the change due to merely perfusing the diabetic heart with normal blood. FRANCES KRASNOW

Experimental study of the action of insulin on normal and diabetic hearts. E. W. H. CRUICKSHANK, B. NARAYANA AND D. L. SHRIVASTAVA. *Indian J. Med. Research 16, 479-512(1928).*—The blood sugar of dogs in India averages 0.112% as compared with 0.09% in the West. The glycogen content of the heart is readily depleted by prolonged administration of volatile anesthetics but is not materially affected by amytal. The action of insulin is not affected by anesthetics. The glycogen content of the normal dog heart is 0.55%; that of the diabetic heart (unfed with sugar) is 0.75%. Insulin, in the presence of available sugar, will effect a storage of sugar as glycogen in the heart muscle. Insulin in excess will, by producing hyperglucemia, effect a marked reduction in glycogen. The diabetic heart perfused with diabetic blood will not utilize sugar. There is no great difference between the power of the normal and diabetic heart to utilize sugar, when both sugar and insulin are added to the blood circulating through them. FRANCES KRASNOW

The comparative action of ephedrine and pseudoephedrine from Indian varieties

of Ephedra on the heart. R. N. CHOPRA AND K. VENKATACHALAM PILLAI. *Indian J. Med. Research* 16, 780-7(1929).—Both drugs have a stimulant action on the sympathetic and vagus nerve endings (ephedrine stimulating the sympathetic ganglia also) and a pressor action. Pseudo-ephedrine stimulates the myocardium while ephedrine depresses it.

Emetine poisoning. F. G. CAWSTON. *J. Trop. Med.* 32, 22-4(1929).—Discussion.

Tellurium therapy in leprosy. RODOLFO STANZIALE. *J. Trop. Med.* 32, 33-6(1929).—Good results are obtained. There was a regression of the tubercle and a lysis of the bacilli.

Some observations on plasmochine. H. R. MAJUNDER. *J. Trop. Med.* 32, 47-9(1929).—Plasmochine is a powerful anti-malarial drug; combination with quinine makes it more powerful. It has none of the disagreeable nervous symptoms of quinine and is thus better tolerated. The toxicity of the drug is not very great.

The action on the frog of intracerebrally injected substances. N. EBBECKE. *Z. Biol.* 88, 465-86(1929).—The anions ( $\text{Cl}^-$ ,  $\text{I}^-$ ,  $\text{SO}_4^{--}$ ,  $\text{PO}_4^{--}$ ) are ineffective, but the cations form a definite series: Li, Na—indifferent; Mg, Ca—sedative and paralyzing; K, Rb, Sr—violently exciting, followed by a paralyzing effect; Cs, Ba exciting and paralyzing effect followed by injury. Convulsions of the strychnine type are obtained if the osmotic pressures of the solns. are increased.  $\text{NH}_4\text{Cl}$  gives a similar effect. Narcotics paralyze from the time of injection to the "wearing off." With alkaloids delay in the onset and disappearance of the paralytic effect are characteristic.

Studies on antagonistic nerves. XXXVI. The influence of parasympathetic poisons on the transmission speed of nerve excitation. HAKAN RYDIN. *Z. Biol.* 88, 531-9(1929).—A method is described for graphic representation of nerve stimulation. Atropine retards the speed of nerve transmission, this action being reversible after washing with Ringer soln. Acetylcholine increases the speed of transmission in most cases. XXXVII. Temporary stimulation under the influence of sympathetic and parasympathetic poison. L. ASHER AND N. SCHEINFINKEL. *Ibid* 540-52.—Atropine lengthens the duration of "chronaxie" while acetylcholine has the reverse effect. Both adrenaline and atropine increase the refractory period; acetylcholine and ergotamine decrease it.

The value of acterol (irradiated ergosterol) in the treatment of thyroparathyroidectomized dogs. JOHN C. BROUGHER. *Am. J. Physiol.* 86, 538-41(1928).—Acterol (irradiated ergosterol, 1 cc. = 100 cc. cod liver oil in vitamin D) given intramuscularly to dogs from the day of removal of the thyroids and parathyroids prevented the development of violent tetany provided the animals were able to consume a Ca-rich diet (milk).

The effect of withdrawal of drinking water on the susceptibility of rats to certain drugs. GEORGE CRISLER. *Am. J. Physiol.* 86, 552-5(1928).—Withholding drinking water from rats for 48 hrs. or more caused depression and increased their susceptibility to morphine and  $\text{MgSO}_4$  (depressants), but decreased it to strychnine (stimulant).

The influence of the daily oral administration of magnesium sulfate or lactose on the blood volumes of normal, beriberi and fasting pigeons. O. W. BARLOW AND M. S. BISKIND. *Am. J. Physiol.* 86, 594-8(1928).—The daily addition of cathartics ( $\text{MgSO}_4$  or lactose) to normal pigeons had no significant effect on red cell count, total vol. or sp. gr. of the blood. In fasting pigeons or pigeons having beriberi,  $\text{MgSO}_4$  or lactose did not affect the loss of body wt., did not alter the blood vol., but did tend to limit the fall in the red cell count usually seen in untreated birds.

Changes in blood sugar following injections of peptone in the dog. W. W. BRANDES AND J. P. SIMONDS. *Am. J. Physiol.* 86, 618-22(1928).—Peptone injected into anesthetized dogs caused a hypoglycemia in the peripheral venous blood during the period of low blood pressure. When the blood pressure rose and the liver became less engorged with blood a rather marked rise in blood sugar occurred.

The effect of ergotamine on phlorhizin glucosuria. A. B. ANDERSON AND M. D. ANDERSON. *J. Physiol.* 65, 456-7(1928).—In previous work (*C. A.* 22, 3229) the effect of tyramine on phlorhizin glucosuria was studied. It is now found that ergotamine and ergotamine do not suppress phlorhizin glucosuria; but rather that they cause a rise in the D/N ratio of a phlorhizinized animal. Conclusion: Phlorhizin does not act on the sympathetic nerve endings in the kidney, thus causing glucosuria.

Some factors affecting the response of rabbits towards insulin. KATHLEEN CULHANE AND S. W. F. UNDERHILL. *Proc. Physiol. Soc., J. Physiol.* 65, xx-xxi(1928).—The following animals were found to cause inaccuracies in the test: (1) Rabbits that

had been used on rough tests and had therefore received doses of insulin varying widely from 0.5 unit per kg.; (2) animals below 1600 and above 3000 g. in wt.; (3) animals that had been in use more than one year; (4) females that had been used for breeding; (5) "Ginger" rabbits and Belgian hares.

J. F. LYMAN

The seat of action of strychnine, veratrine, and barium in the striated muscles of the frog. GIUSEPPE RUSSO. *Boll. soc. ital. biol. sper.* 3, 956-9(1928).—An isotonic soln. of  $\text{BaCl}_2$  at  $p_H$  7.4 was allowed to act on the distal and on the proximal portion of the sartorius muscle. While the distal portion reacted regularly to Ba with fibrillary twitchings and contractures, the proximal portion showed only contractures. A curarized muscle responded to the action of Ba with fibrillary twitching and contractures like a normal muscle, whereas a muscle paralyzed by strychnine lost entirely the property to respond to Ba with fibrillary contractions but still exhibited contractures. The frog was paralyzed completely by strychnine and then a soln. of veratrine (1:1,000,000) in Ringer was allowed to act on the muscle sepd. from the body. After a few mins., the muscle gave typical veratrine curves when stimulated by an elec. current. *Conclusions.*—(1) The two most characteristic effects of Ba on the mech. function of the muscle, twitchings and contractures, can be differentiated in the frog. (2) Fibrillary twitchings are produced by a mechanism located in the neuro-muscular synapsis between the seat of action of curare (external) and the curare-like action of strychnine (internal). The mechanism of the contractures is probably situated more internally than the former. (3) Veratrine acts on the muscle of an animal paralyzed by strychnine; hence its seat of action is more internal than that of strychnine, namely, on the interior structures of the muscle fibers.

P. M.

The reaction to adrenaline of the vascular region of inflamed tissues. MARIO GIANOTTI. *Boll. soc. ital. biol. sper.* 4, 3-7(1929).—Adrenaline acted less intensely on the inflamed tissue of rabbit ears than it did on normal tissue. Various hypotheses are advanced to explain this behavior.

PETER MASUCCI

Histological alterations of the nervous system in insulin intoxication. MARIO GOZZANO. *Boll. soc. ital. biol. sper.* 4, 73-6(1929).

PETER MASUCCI

The liberation of sulfite from sodium thiosulfate in the organism. E. MENECHETTI. *Boll. soc. ital. biol. sper.* 4, 107-9(1929).—M. proved that  $\text{Na}_2\text{S}_2\text{O}_3$  when injected into the organism is transformed as follows:  $\longrightarrow \text{S}_2\text{O}_3 \longrightarrow \text{polythionates} \longrightarrow \text{SO}_4$ . The detection of  $\text{SO}_3$  in the presence of  $\text{S}_2\text{O}_3$  and polythionates was accomplished by the following method: (a) The reagent used was an aq. soln. of fuchsin 0.20 g. and methyl green 0.07 g. per l. One drop of this reagent when added to 2 cc. of urine or serum produces a violet-red color; if sulfites are present the color disappears at once. Thiosulfates, polythionates and sulfates do not interfere. In this manner it is possible to detect in 2 cc. of urine 0.00004 g. sulfite ( $\text{Na}_2\text{S}_2\text{O}_3 + 7\text{H}_2\text{O}$  1:50,000); in 2 cc. of serum 0.00005 g. (1:40,000). (b) Thiosulfate was detd. in the presence of  $\text{SO}_3$  by acidifying the urine with HCl so that S sepd. out. 0.0004 g. thiosulfate or  $\text{Na}_2\text{S}_2\text{O}_3 + 5\text{H}_2\text{O}$  1:5000 was detd. by this manner in 2 cc. of urine. Serum was acidified with HCl until acid to litmus; the S sepd. out and was reduced to  $\text{H}_2\text{S}$  which was detected with  $(\text{AcO})_2\text{Pb}$  paper.  $\text{Na}_2\text{S}_2\text{O}_3 + 5\text{H}_2\text{O}$  1:4000 can be detected in this manner. The  $\text{SO}_3$  test is more sensitive than the  $\text{S}_2\text{O}_3$  test. With the above methods,  $\text{Na}_2\text{S}_2\text{O}_3$  and  $\text{Na}_2\text{SO}_3$  were injected intravenously and subcutaneously into dogs. Even by the injection of strong doses of  $\text{S}_2\text{O}_3$  and small doses of  $\text{SO}_3$ , it was not possible to detect the presence of either. The liberation of  $\text{SO}_3$  following the injection of  $\text{Na}_2\text{S}_2\text{O}_3$ , therefore, cannot be demonstrated.

PETER MASUCCI

Colloidal sulfur as an antidote for corrosive sublimate. E. MENECHETTI. *Boll. soc. ital. biol. sper.* 4, 133-5(1929).—Three methods are described to show that S in the organism can form sulfides with salts of Hg. Rabbits and guinea pigs were poisoned with  $\text{HgCl}_2$  administered via the gastric route or injected subcutaneously. Raffo's colloidal S failed to give any protection, but Wackenroder's S allowed animals to survive which had received lethal doses of  $\text{HgCl}_2$ . Therefore, as an antidote for  $\text{HgCl}_2$ , a colloidal S is required whose degree of dispersion and stability is such that it can pass into the general circulation, be fixed by the organs and be released gradually, continuously, and safely, in the form of  $\text{H}_2\text{S}$ . Raffo's S is too highly dispersed and Heffter's S is too little dispersed for this purpose.

PETER MASUCCI

The propagation of the excitement caused by veratrine and nicotine in the sartorius of the toad. G. E. GHIRARDI. *Arch. sci. biol. (Italy)* 13, 185-205(1929).—Nicotine and veratrine applied in minute doses to a part of the muscle cause an excitement that is extended to the other parts and can be discovered by stimulating to contraction. Larger doses produce contractions transmitted to the normal part, completely in the case of nicotine, partly for veratrine. While the tension after veratrine is in-

creased, spontaneous contractions are imposed and transmitted to the normal part of the muscle. Veratrine diffuses slowly through the muscle. The tension and contraction are two different functions of the fibers and the sarcoplasmia. A. E. MEYER

**Vital staining in the eye.** F. P. FISCHER. *Kolloidchem. Beihefte* 28, 333-42 (1929).—Acid dyestuffs pass after intravenous injection from the blood into the aq. humor. They stain the iris, but not the ciliary body. Such dyestuffs are fluorescein, uranin, eosin, Me-eosin, aescorcin and trypan blue. Basic dyestuffs, as methylene blue, toluidine blue, methylene green, alizarin blue S, pyronine G, safranin O, fuchsin basic and Me violet, do not pass, but stain the ciliary epithelium. The ciliary epithelium is an O-producing, or anodic tissue, the iris a cathodic one. The aq. humor is more basic than blood. A. E. MEYER

**Glukhorment in the treatment of diabetes.** MARCEL LABBÉ AND FLORIDE NEPVEUX. *Presse méd.* 36, 913-17(1928).—Glukhorment does not have a disturbing effect on the stomach, as synthalin has. The organism does not become tolerant to it. Its effect is less intense and less reliable than that of insulin. The chem. compn. is not known; it is supposed to be a mixt. of pancreatic ext. and synthalin. A. E. MEYER

**Investigation concerning the diuretic action of urea in the treatment of exudates and transudates.** D. SIMICI, I. MARCON AND M. POPESCO. *Presse méd.* 36, 946-50 (1928).—Urea acts as a diuretic in both health and disease proportionally to the amt. given. The action lasts 24 hrs. after the last dose; blood urea is normal after 24-48 hrs. The dose is 25-50 g. over a period of 4 to 7 days. Chlorides and uric acid also are eliminated in a larger amt. A. E. MEYER

**Study of the action of some double thiosulfate salts in normal and tuberculous guinea pigs.** JORGE GASCON. *Rev. facultad cienc. quim.* 5, Pt. 1, 41-72(1928).—The methods of prepn. of the following compds. are given: *sodium aurothiosulfate*, *sodium argentothiosulfate*, *sodium cuprous thiosulfate*. The Au salt has no hemolytic effect on the red corpuscles of the rabbit, nor on the blood count and hemoglobin content. The lethal dose in guinea pigs is 0.037 g. per kg. The Ag salt has a strong hemolytic action even in  $1/10000$  diln. The soln. ppts. protein soln. Intravenous injections of 0.01 g. in 2 cc. saline have no influence on the blood count and hemoglobin. The lethal dose is 0.25 g. per kg. Subcutaneous injections cause injuries of the tissues. The Na-Cu salt could not be tested for its hemolytic action as it is not stable at 37°. 0.01 g. has no effect on the blood count or hemoglobin content in the rabbit. The lethal dose in subcutaneous injections in the guinea pig is 0.09 g. per kg. The injections are injurious to the tissues. In the expts., the guinea pigs were infected with *B. tuberculosis* and later treated subcutaneously with the salts in doses of 0.0005-0.01 g. The Ag salt cannot be given in higher doses than 0.0005 g. every fifth day. No improvement was observed; the same result was obtained with the Cu salt. The Au salt can be given in higher dose, but had no influence on the disease. A. E. MEYER

**Isolation of methanol from tobacco smoke.** CARL NEUBERG AND MARIA KOBEL. *Biochem. Z.* 206, 240-4(1929).—MeOH was demonstrated in tobacco in the form of a Me ester of pectinic acid and as a ether compd. in lignin. The MeOH has now been isolated and identified by its b. p. and elementary compn. in the tobacco smoke. S. MORGULIS

**Potassium permanganate in the treatment of pneumonia.** JOHN L. CHESTER. *Ann. Internal Med.* 2, 1175-84(1929).—KMnO<sub>4</sub> seems to have a true sp. action on the pneumococcus. Two grains are dissolved in 750 cc. of water and the soln. given in 120 cc. amts. per rectum. JOHN T. MYERS

**Glycogenolysis due to adrenaline in hepatic disease.** SELLING BRILL. *Arch. Surgery* 18, 1801-16(1929).—Patients with widespread disease of the liver will give after the injection of adrenaline an almost flat blood sugar curve. They should be given large amts. of glucose pre- and postoperatively. JOHN T. MYERS

**Creolin therapy in rabbit coccidiosis.** B. J. KRIJGSMAN. *Centr. Bakt. Parasitenk.*, I Abt., 111, 426-8(1929).—The following mixt. was substituted for the drinking water of infected rabbits and had considerable value: creolin, 2.5 cc.; NaHCO<sub>3</sub>, 4.0 g.; syrup simpl., 400 cc.; oil of anise, 4 drops; and water, 2000 cc. JOHN T. MYERS

**The treatment of anemia with novogen.** HAROLD BORCHARDT. *Folia Haematol.* 38, 44-51(1929).—"Novogen" is made from animal blood. It contains, chiefly, hemoglobin, lecithin, Ca phosphate, maltose and Fe and Mg peptones. It is useful in the treatment of anemia in 3 teaspoonful doses daily. JOHN T. MYERS

**The fate of colloidal iron administered intravenously.** II. Long experiments. CYRIL J. POLSON. *J. Path. Bact.* 32, 247-60(1929); cf. C. A. 22, 4651.—The distribution of Fe resulting from intravenous administration was observed for 14 months. It is excreted largely by the cecum and the kidneys. An excess is stored principally

in the liver, but some goes from the liver to the lymph nodes where it remains in the body for some time. Some also goes to the lungs probably by way of the spleen, where it is held for a time, essentially as a foreign substance. JOHN T. MYERS

The treatment of experimental tuberculosis by calcium administration. J. CLIFFORD HOYLE. *Quart. J. Med.* 22, 451-9(1929); cf. *C. A.* 23, 1173.—There is no evidence that Ca exerts a direct therapeutic effect on tuberculosis. Bibliography. JOHN T. MYERS

The pharmacology of the strychnine derivatives (ethylstrychnine or strychnal), MARIO AIAZZI MANCINI. *Arch. farmacol. sper.* 27, 225-38(1929).—The chem. behavior of ethylstrychnine (I) resembles very much that of strychnine (II). I treated with  $K_2Cr_2O_7$  and  $H_2SO_4$  gives a violet coloration, which differs only very slightly from that given by II. The sensitiveness of I toward a few reagents was compared with that of II: with  $HgCl_2$ , I 1:5000, II 1:2000; with Bouchardat's reagent, I 1:30,000, II 1:30,000; with picric acid, I 1:3000, II 1:6000; with Mayer's reagent I 1:350,000, II 1:200,000. The pharmacol. action of I in warm-blooded animals is almost identical with that of II. The fatal doses of I were 25-28 mg. per kg. for the rabbit and 25 mg. per kg. for the guinea pig, while the corresponding fatal doses of II are 0.6 and 3-3.5 mg. per kg. (Schmiedeberg). Thus the toxicity of I is much smaller than that of II. Marked stimulations of the bulbar centers were obtained with I in doses that were non-convulsive and did not primarily affect the blood pressure. Since I is much less toxic than II, I may become of value as a respiratory stimulant. In cold-blooded animals the action of I differs much from that of II, since with I the paralyzing and curarizing action prevails. Rabbits to which a non-convulsive dose was administered did not show convulsions when the same dose was given for about 12 days in succession. From this and from the fact that the pos. test for I in the urine with Mayer-Valzer's reagent disappears within 48 hrs. after the last administration, A. concludes that I has no cumulative action. G. SCHWOCH

Behavior of thyroxine in the animal body. EMIL ABDERHALDEN AND ERNST WERTHEIMER. *Arch. ges. Physiol.* (Pflüger's) 221, 82-92(1928); cf. *C. A.* 22, 4160.—Thyroxine solns. are deprived of active principle by the various tissues to different degrees, muscle being most active, liver of minimal effect. Heated tissue exerts a greater effect than does the fresh organ, and tissue exts., fresh or heated, are without effect. G. H. SMITH

Effect of parenterally introduced foreign stimulating agents upon compensatory renal hypertrophy after unilateral nephrectomy in rats. O. PECZENIK AND E. BEER. *Arch. ges. Physiol.* (Pflüger's) 221, 215-29(1928).—The increase in wt. of the kidney remaining after unilateral nephrectomy in rats is much greater if the rats are injected with caseosan. Since the kidney tissue, as detd. by dry wt., is increased this represents a true hypertrophy. Phlogetan, which lacks protein, exerts practically no stimulating action. Caseosan alone, or in combination with phlogetan, has no effect upon the excretion of water, N, or urea by normal animals, and injections of these substances prior to operation (nephrectomy) prevent the water and urea retention which are observed after operation in uninjected animals. G. H. SMITH

Fixation of potassium in muscle. Reply to Neuschlosz. RUDOLF HÖBER. *Arch. ges. Physiol.* (Pflüger's) 221, 478-85(1929).—The conclusion of Neuschlosz (*C. A.* 20, 3498) to the effect that there is a connection between tonus formation and K fixation is questioned. G. H. SMITH

Formation of urine in the frog kidney. XVI. Effect of caffeine on the oxygen utilization of the kidney and the mechanism of caffeine diuresis. KARL J. ANSELMINO. *Arch. ges. Physiol.* (Pflüger's) 221, 633-40(1929).—By applying Warburg's method to minced kidney tissue it was found that small doses of caffeine do not modify the respiration, although it is inhibited by larger doses. Small doses of caffeine did not materially modify anaerobic glycolysis. G. S. SMITH

Effect of infusion of isotonic saline solutions on the respiration. HERMINE BAER. *Z. Kinderheilk.* 46, 45-54(1928).—No sp. effects of the saline injections upon the metabolism could be detected. G. H. SMITH

Poisoning by tetraethyl lead. F. HEIM DE BALSAC, E. AGASSE-LAFONT AND A. FEIL. *Progrès méd.* 1928, 1275; *Ann. hyg. publ. ind. sociale* 1929, 55-6. G. T.

Cinchophen preparations and their action and mode of action upon the urate excretion. TENMIN KAKU. *Acta Med. Keijo* 11, 47-66(1928).—See *C. A.* 23, 2215. A. J. VORWALD

The pharmacological action of the essential oils from *Atractylis ovata* Thunb. SANGTAE KIM. *Acta Med. Keijo* 11, 83-104(1928).—The Chinese drug "Jutsu," an ext. of *Atractylis ovata* Thunb, when injected into the dorsal lymph sac of frogs causes a

weakening of respiratory movements with a gradual motor paralysis and finally a cessation of respiration. When applied to a beating frog heart either excised or *in situ* it causes a paralysis and finally an arrest of heart beat in diastole. With subcutaneous injections into mice there appears an increased reflex activity, increased perspiration and convulsions with respiratory failure. Subcutaneous injections into rabbits cause a slight motor paralysis of the extremities and a transient respiratory increase and a fall of blood pressure. Perfusion of blood vessels causes a dilatation and when applied to smooth muscle organs there occurs a loss of tonicity. The skeletal muscles and motor nerves are slightly influenced. With greater doses the above effects are increased.

ARTHUR J. VORWALD

**A study of the toxicology of bismuth.** R. FABRE AND M. PICON. *J. pharm. chim.* [8], 8, 249-58, 297-308(1928).—The recent therapeutic use of oil-sol. Bi salts, e. g., camphocarbonate (cf. *C. A.* 23, 2215) in large doses suggested a study of the resulting distribution of Bi in the various organs. First, the methods of detg. small quantities of Bi are reviewed, including the electrolytic methods of Hollard and Bertiaux (*C. A.* 14, 913), Schoch and Brown (*C. A.* 10, 2442) and Pregl's microchem. method (*C. A.* 17, 2253). For quantities less than 1 mg. the Bayle and Amy method (*C. A.* 22, 3108), (app. illustrated), gave excellent results. Of colorimetric (confirmatory) detns., the Labat and Péry method (*C. A.* 18, 1097) is sensitive to 5 mg. Bi per l. in 2 cc. of soln. taken. The method of Laporte (*C. A.* 18, 1259) indicates 0.1 mg. Bi accurately within 3%. By applying the use of the spectrophotometer to this method, an exact method of detg. Bi may be developed based on an observed linear variation of optical density with diln. of Bi at the wave length of 5200 Å. U. (cf. *C. A.* 22, 4402). As to the content of Bi in the various parts of the organism, the Bi, whether introduced by intramuscular (rabbit and dog) or intravenous (rabbit) injection of oil soln. of Bi camphocarbonate, becomes fixed in notable quantities in the liver and the kidneys; very little Bi is found in the brain even after prolonged treatment. The blood carries a notable proportion. Aside from the urinary duct, the salivary secretion, also the hair, play an important part in the elimination of Bi.

S. WALDBOTT

**Chemotherapeutic researches on cancer.** A. T. TODD, *et al.* *Cancer Rev.* 14, 325(1929).—The substance chiefly used in these researches and in the treatment of cases of malignant disease was a colloidal Pb selenide alone or combined with Na thio-sulfate. Thereby it was hoped to combine the supposed specific action of Pb upon cancer cells with the analgesic properties of Se. The dosage first given was 40 mg. of Pb, increasing to 80-100 mg. with a full course amounting to 0.5 g. With the prepn. D4S 5.0 mg. are given, followed by increasing doses at weekly intervals. Numerous patients showed mental symptoms of some severity, and other symptoms of Pb poisoning occurred, but were not very marked. The blood changes during treatment were followed, and the serum lipase was estd., but the value of the latter is not evident. 44 cases of malignant disease in man have been treated. In 8 cases there is stated to have been relief from pain, and retardation of the growth is claimed in 8 cases. Fourteen patients were alive 2-8 months after the cessation of treatment, but the av. survival of 20 out of 25 patients who died was under 6 months. No case of "cure" is recorded. An investigation was also made of the action of different Pb compds. on various enzymes and of their action upon tumor-bearing rats and mice. The results of the latter expts. do not appear to be very conclusive. The prepn. of various colloids of Pb, Se and TI is described. Analysis of various organs and growths after Pb treatment showed no selective deposition of Pb in the growths.

H. G. WELLS

**Electrocardiographic studies on the actions of drugs. I. The vagus in ether anesthesia.** HARRY GOLD, PATRICK L. GRYZWACZ AND VALENTINE A. NOWICKI. *Am. Heart J.* 4, 336-45(1929).—Results were recorded on the susceptibility of the cardio-inhibitory nerves to stimulation by morphine in the dog. Ether depresses the vagus and may abolish partially or entirely the effects of stimulation of these nerves by morphine. After large doses of morphine, deep ether narcosis may abolish vagus effects upon the sinus and not those upon conduction. Inhaled ether in doses which do not paralyze respiration depresses the vagi. Atropine is still effective after the full effects of ether have been induced.

R. C. WILLSON

**An experimental study of the influence of ferromagnetic cubic and paramagnetic amorphous iron oxide on the blood.** C. A. DOAN, F. R. SABIN AND C. E. FORKNER. *Am. J. Med. Sci.* 177, 201-8(1929).—The Fe was administered by mouth in doses of either 3 or 6 mg. per day to rabbits weighing from 1800 to 2800 g. Ferromagnetic  $Fe_3O_4$  failed to aid in the regeneration of hemoglobin after simple anemia and seemed to delay the return to normal.

R. C. WILLSON

**The pharmacology of some ethylene-halogen compounds.** GENÉ H. KISTLER AND

ARNO B. LUCKHARDT. *Anesthesia and Analgesia* 8, 65-74(1929).—EtOH, Et<sub>2</sub>O, C<sub>2</sub>H<sub>5</sub>Br<sub>2</sub>, C<sub>2</sub>H<sub>4</sub>Cl<sub>2</sub>, C<sub>2</sub>H<sub>4</sub>I<sub>2</sub>, paraldehyde and CHCl<sub>3</sub> were used. When injected intravenously in small doses into anesthetized dogs, all the ethylene halides coexhibited depressant effects upon respiration, blood pressure and knee jerk. The toxicity increases in the order: C<sub>2</sub>H<sub>4</sub>Br<sub>2</sub>, C<sub>2</sub>H<sub>4</sub>I<sub>2</sub> and C<sub>2</sub>H<sub>4</sub>Cl<sub>2</sub>. When C<sub>2</sub>H<sub>4</sub>Cl<sub>2</sub> (0.5 cc. per kg.) was administered by mouth to the dog without anesthesia there resulted excitement, incoordination, salivation, vomiting, nausea and depression; all effects appeared within 30 mins. after introduction. Larger doses were vomited.

R. C. WILLSON

The effect of anesthetics on the red blood cells. WILLIAM WEBSTER. *Anesthesia and Analgesia* 8, 106-9(1929).—N<sub>2</sub>O, ethylene, EtCl, CHCl<sub>3</sub> and Et<sub>2</sub>O were examd. There is an increase in the no. but not the size of the red cells.

R. C. WILLSON

The action of different drugs on the blood pressure of the pigeon. TSUNEMICHI HAYAMA. *Folia pharmacol. japon.* 7, 14-5(1928); *Ber. ges. Physiol. expil. Pharmacol.* 47, 347.—Adrenaline and digitalein increase the blood pressure, although larger doses of the latter cause a secondary decrease. Acetylcholine, choline, pilocarpine and oryzanin (a vitamin B prepn.) effect an increase, larger doses causing a secondary decrease. Physostigmine and atropine have no effect.

R. C. WILLSON

The biologic diagnosis of drunkenness. II. The phagocytic capacity in experimental alcoholic intoxication. VINCENZO M. PALMIERI. *Giorn. batteriol. e immunol.* 2, 697-704(1927); *Ber. ges. Physiol. expil. Pharmacol.* 47, 175.—When 8-5 cc. abs. alc. per kg. body wt. was introduced into the stomachs of dogs, there was a decrease in the phagocytic capacity, Simon's index and Wright's index. The depressions reached their height 2-6 hrs. after the ingestion and were parallel with the amt. of alc. introduced.

R. C. WILLSON

The effect of the intravenous administration of magnesium sulfate. Experimental studies. H. J. STANDER. *J. Am. Med. Assoc.* 92, 631-6(1929).—"MgSO<sub>4</sub> in doses ranging from 0.05 to 0.49 g. per kg. body wt., administered to dogs either intramuscularly or intravenously in 10 or 25% soln., did not produce any marked changes in the blood on chem. examn. but did produce definite histological changes in the liver and kidneys, in the form of moderate necrosis in the central part of the liver lobule and moderate degeneration in the convoluted tubules of the kidneys. MgSO<sub>4</sub> when administered in large amts. is toxic and may produce death."

R. C. WILLSON

The action of histamine on the alkaline reserve. SALOMON KATZENELBOGEN. *J. Am. Med. Assoc.* 92, 1240-1(1929).—Intramuscular injections of 0.5-1.0 cc. histamine (1:1000) produced an increase in the blood alk. reserve in 14 of 18 rabbits. The increase is noted even 25 mins. after injection, but is more pronounced after 60 mins., usually returning to the initial value within 100 mins.

R. C. WILLSON

The influence of alkalies on the motility and secretion of the stomach. MAX DEGENER. *Münch. med. Wochschr.* 75, 1838-40(1928).—The stomach was emptied and 300 cc. 5% alc. soln. given to stimulate its action. At the height of its secretion (40-60 mins. later) 2.5 g. magnesia usta in H<sub>2</sub>O was given and its effects were studied. The emptying time of the stomach was shorter. In hyperacidity there was a neutralization up to 30 mins., while in normal acidity this neutralization lasted up to 1 hr.

R. C. W.

The action of bile acids on the heart. T. HOSOKAWA. *Okayama-Igakkai-Zasshi* 39, 593-603(1927); *Ber. ges. Physiol. expil. Pharmacol.* 47, 283.—Cholic acid (0.03-0.01%) added to Ringer soln. increases the beat vol. of the frog heart; 0.002-0.005% desoxycholic acid and Ringer soln. have the same effect. The first decreases, then increases the beat frequency; the latter decreases it. This action is independent of the pH of the soln. and of the vagus nerve. Ringer soln. flowing through the liver increases the beat vol. of the heart but to a smaller degree than Ringer soln. plus 0.03-0.04% cholic acid.

R. C. WILLSON

The influence of larger doses of morphine on the respiration. MASAMI NISISITA. *Okayama-Igakkai-Zasshi* 40, 797-818(1928); *Ber. ges. Physiol. expil. Pharmacol.* 47, 350.—The optimal inhibiting dose in rabbits is 20 mg. per kg. body wt. This dose removes the irritability of the respiratory center toward CO<sub>2</sub> (5-10%). After the completion of the CO<sub>2</sub> inhalation there is a transitory respiratory increase and a "detoxification stimulation." Larger doses of morphine alone or in combination with CO<sub>2</sub> respiration, lobeline and atropine sulfate always increase the reaction capacity of the respiratory center. The chief cause of death is not respiratory paralysis but the convulsant action of morphine.

R. C. WILLSON

Studies on the regulation of blood coagulation from the pharmacological point of view. II. The influence of some sympathetic poisons on the blood coagulation. HISASHI TANAKA. *Okayama-Igakkai-Zasshi* 40, 836-59(1928); *Ber. ges. Physiol. expil. Pharmacol.* 47, 272.—Small doses (0.001-0.01 mg. per kg.) of adrenaline injected intrav-

enously into rabbits reduce the coagulation time by 50–66%, increase the fibrinogen and thrombin and decrease the antithrombin. Large doses (0.03–0.05 mg. per kg.) reverse these changes. The action of small doses of adrenaline is reversed by preliminary administration of atropine or yohimbine. Tyramine (0.005–0.01 g. per kg.) and tetrahydro- $\beta$ -naphthylamine in small doses accelerate blood coagulation, while larger doses inhibit it.

R. C. WILLSON

**Chemical modifications of blood following intravenous injection of urea.** B. VALERA FUENTES, J. DUOMARCO AND A. MUNILLA. *Rev. asoc. med. Argentina* 41, 885–909 (1928); *J. Am. Med. Assoc.* 92, 272.—Intravenous injections of urea (1.5–5.0 g. per kg. body wt.) produced toxic symptoms in dogs similar to those produced by renal deficiency during the evolution of uremia. Death follows when non-protein N reaches 500 mg. per cc. The ratio, coeff. of urea N : total N, which normally is 0.5, reaches 0.9, the total blood N exceeding 100 mg. No modification of the blood uric acid, creatine and creatinine was produced. The mineral metabolism was unchanged as regards Ca, NaCl and inorg. P.

R. C. WILLSON

**The Doeberner reaction.** VII. Syntheses with  $\beta$ -aminoanthracene (CIUSA, MUSAJO) 10. Synthesis of an isomer of thyroxine and of related compounds (HARRINGTON, MCCARTNEY) 10. Synthesis of isomeric ephedrine and their homologs (NAGAI, KANAO) 10. 3,4-Methylenedioxyphenylarsonic acid (BALABAN) 10. Chemotherapy of some Br derivatives of phenylarsonic acids and arsenobenzenes (HAYTHORNTHWAIT) 10. Some derivatives of arylthioarsinous acids (BARBER) 10.

## I—ZOOLOGY

R. A. GORTNER

**The increased consumption of oxygen of marine animals under the influence of high pressures. Its variation as a function of the duration of compression.** MAURICE FONTAINE. *Compt. rend.* 188, 662–3 (1929); cf. C. A. 23, 2502.—In studying the effect of compression on the  $O_2$  consumption of *Pleuronectes platessa* it was found that the percentage above normal consumption increased with time up to 90 mins. and then began to fall. The values for a small animal (0.120 g.) were higher than those for a larger one (0.275 g.). The pressure employed was 100 kg. per  $cm^2$ .

D. D.

**The iodine content in species of fish from the east and west coasts of U. S. A. Preliminary communication.** GULBRAND LUNDE AND JENS BØE. *Tids. Kemi og Bergvesen* 8, 139–40 (1928); cf. C. A. 23, 2193.—Lunde has earlier shown that the I content in species of fish from the Norwegian coast is much higher than that found by other investigators in fish from other places. The authors have examd. a series of samples from the east coast of U. S. A. The samples were collected at Woods Hole, Mass. in June and July, 1928. The results are: examd. material collected at La Jolla, Cal., in June, 1928. *Merluccius* from the northeast coast of N. America contained in mg. I per kg. in the muscle, resp.: *Brevoortia tyrannus* (menhaden), 0.46–0.90; *Pollachis* (cod), 0.42–1.52; *Scomber scombrus* (mackerel), 0.12–0.27; *Melanogrammus* (haddock), 6.74–24.07; *Brosimius brosme* (cusk), 0.17–0.49; *Pseudopleuronectes* (flounder), 0.53–1.89; *Gadus callarias* (cod), 0.79–2.82. Analysis of muscle from the east of southern Calif. gave: *Scomber japonicus* (mackerel), 0.099–0.2; *Paralichthys oblongus*, 0.12–0.18; *Paralichthys biforniensis*, 0.318–1.298; *Paralabrax clathratus* (kelp bass), 0.040–0.068; *Lepidion* (sheepshead), 0.068–0.364; *Emtrioloca jacksoni* (black perch), 0.040–0.068. The I contents found by the authors are much higher than the analyses of fish from the U. S. Bur. of Fisheries, Document No. 967). The I content of the fish from the American coast is much smaller than that of fish from the Norwegian coast. Only the haddock approximates the I content of fish from the Norwegian coast.

A. DROGSETH

**A note on hemerythrin.** G. F. MARRIAN. *Brit. J. Exptl. Biol.* 4, 357–64 (1927); *Physiol. Abstracts* 13, 570.—Hemerythrin solns. have been prepd. from the body fluid of *Phascolosoma* and dissoen. curves drawn between the temps. of 0° and 53°. The dissoen. curve is not appreciably affected by changes of  $p_H$  within the range in which the pigment is relatively stable ( $p_H$  6 to 10). The heat of formation of oxyhemerythrin is calcd. at 10,350 calories per gram mol. The spectroscopic examn. of the various compds. is described. The presence of heme in the mol. has not been demonstrated, nor can the pigment function as a peroxidase.

H. L. D.

**Carbon dioxide from the nerves of cold-blooded vertebrates.** G. H. PARKER. *Am. J. Physiol.* 86, 490–504 (1928).—A colorimetric method for  $CO_2$ , sensitive down to  $2.5 \cdot 10^{-5}$  cc., is described. The leg nerves of the frog produced 0.0022 mg.  $CO_2$  per g. nerve per min. in winter and 0.0034 mg. in summer. The lateral-line nerve of the dog-

fish produced 0.0024 mg.  $\text{CO}_2$  per g. of nerve per min., the nerve fibers producing about 66% more than did the nerve as a whole. Each nerve impulse in a series of impulses passing over 1 cm. of the lateral-line nerve of the dogfish liberated approx.  $2.8 \cdot 10^{-13}$  mg. of  $\text{CO}_2$ . J. F. LYMAN

The oxygen consumption of the frog heart. I. A J CLARK AND A. C. WHITE. *J. Physiol.* 66, 185-202(1928).— $\text{O}_2$  consumption was measured on a Barcroft manometer or by Weizsäcker's method. The resting metabolism of the frog heart was about 25% of that at moderate work.  $\text{O}_2$  consumption due to contraction varied directly with the diastolic vol. and was not influenced by the resistance against which the heart contracted. Heart muscle was very sensitive to acid, being arrested by a fluid of about  $\text{pH}$  6.2 which seemed to be sufficient to inhibit the initial anaerobic break-down process. II. Effect of lipoids, ions and narcotics. *Ibid* 203-16.—Resting metabolism in frog heart was not markedly changed by lack of  $\text{Ca}$ , excess of  $\text{K}$ , narcotics, soaps or lipoids. Ionic changes and narcotics depressed the  $\text{O}_2$  consumption due to contraction. Blood serum, alc ext. of blood serum and  $\text{Na}$  oleate increased the metabolism of hypodynamic hearts. The chem. changes which cause the resting  $\text{O}_2$  consumption appear to be of a different nature from the catabolic processes with contraction. J. F. LYMAN

The tarsal chemical sense of the screw worm fly, *Cochliomyia macellaria* Fab. CYRIL E. ABBOTT. *Psyche* 35, 201-4(1928).—These flies can easily distinguish between pure water and a sucrose soln. when the solns. are allowed to touch the tarsi. Water vapor was not an important factor in the response but water starvation increased the no. of responses. There was no difference in the response of the sexes. Urea solns did not call forth feeding responses; they appeared to be repellent. C. H. R

Insect nutrition and metabolism. A summary of the literature. B. P. UVAROV. *Trans. Entomol. Soc. London* 1928, 255-343.—A very complete summary of the literature upon insect nutrition and metabolism. The information is arranged under the following headings: the food of insects (classification, phytophagous, saprophagous, carnivorous, special foods, food selection); chem. compn. of insects and their products (ash, N substances, fats and allied substances, carbohydrates, pigments, secretions, excretions); enzymes (digestive enzymes and others); metabolism (N substances, fat, glycogen and other carbohydrates, ash); influence of diet on growth and reproduction (N, carbohydrates, fats, mineral elements, vitamins, endocrine glands and their secretions, complete artificial foods for insects); bibliography (24 pages). C. H. R

The relation between temperature and the pedal rhythm of *Balanus*. WILLIAM H. COLX. *J. Gen. Physiol.* 12, 599-608(1929).—The frequency of the pedal movements of the rock barnacle, *B. balanoides*, increases with temp.; the data show 3 groups of thermal increments and 3 critical temps. The values ( $\mu$ ) computed from the Arrhenius formula are largely those previously found to be associated with respiration and neuromuscular activities. C. H. RICHARDSON

The function of nutrients dissolved in water on the metabolism of aquatic animals. X. The significance of the dissolved nutrients for the metabolism of young carps. BORIS KOSTOMAROV. *Arch. Hydrobiol.* 19, 31-65(1928).—Young carps (*Cyprinus carpio*) (3 groups) were (I) not fed, but were kept in nutritive solns., or (II) fed with daphniae, etc., or (III) kept unfed in pure tap water. At the end of the expts. the solid matter and the ash content were detd. separately in head, body and intestines. Peptone + glucose, peptone + saccharose, peptone + glucose + saccharose, ext. of dried daphniae, ext. of dried fish, ext. of meadow hay, yeast ext., concoction of hay, and hemolyzed ox serum served as nutrient solns. The fish of group I were able to utilize the dissolved substances in order to maintain their metabolism, though the amts. taken up were not quite sufficient to allow the fish to maintain all their bodily functions. No formation of new tissue occurred. The decrease of the solid matter was always smaller in I than in III, especially in the heads. From this it is concluded that I did not hunger as much as III. The exts. seemed to be more suited for utilization than the solns. of chemically pure substances. The metabolism was greater in the summer than in the winter. Numerous references are given. G. SCHWOCH

Precipitin reactions with various tissues of *Ascaris lumbricoides* and related helminths. GRAEME A. CANNING. *Am. J. Hyg.* 9, 207-26(1929).—Antigens prepd. from single germ layers of *Ascaris lumbricoides* induce antibodies which give reactions most intense with the homologous antigen. The highest degree of tissue specificity is exhibited by the anti-cuticle serum; specificity is less with anti-egg and anti-sperm sera. As regards species specificity the anti-sperm serum reacts with the greatest range of related ascarids. G. H. SMITH

Surface permeability of marine invertebrates as the cause of the toxicity of sea-water of abnormal composition. ALBRECHT BETHM. *Arch. ges. Physiol.* (Pflüger's)

221, 344-62(1928).—In the forms studied, *Carcinus maenas* and *Aplysia punctata*, the blood gives higher values for Ca and K than does the sea water, while in *Carcinus* the Mg of the blood is lower than that of the water. If brought into an artificial sea water containing a deficiency or excess of an ion the blood changes correspondingly, the change taking place more promptly in *Aplysia* than in *Carcinus*. Permeability was demonstrated for Ca, K, Mg and Cl. Reduction in Ca causes a fall in tonus and reflex irritability, changes which are reversible.

G. H. SMITH

Effect of different concentrations of calcium salts on the frog heart in the early summer. BRUNO KISCH. *Arch. ges. Physiol.* (Pflüger's) 221, 469-73(1929).—The Ca requirements of the heart of the summer frog are greater than those of the winter frog, but the necessity for increased amts. of Ca does not persist throughout the summer. When the Ca is reduced disturbances of heart action result.

G. H. SMITH

Antagonism and synergism in the effect of magnesium and calcium salts on the heart. BRUNO KISCH. *Arch. ges. Physiol.* (Pflüger's) 221, 474-7(1929).—With respect to contractility the frog heart in early summer gives evidence of an antagonism between Mg and Ca salts. In the autumn this is lacking.

G. H. SMITH

Properties of the cutaneous secretions of certain tree-frogs near Rio de Janeiro. J. VELLARD. *Compt. rend.* 188, 1064-6(1929).—The secretions were examd. of *Hyla faber*, *H. albomarginata*, *H. crospedopsila*, *Trachycephalus nigromaculatus*, *Phyllomedusa burmeisteri*. The solns. were rich in mucus, opalescent, and, with exception of that from the last, coagulated by heat, alc., and strong acids. The fourth one had a  $p_H$  of 6.9, the last, 6.7; both of these gave the biuret and xanthoproteic, but not the Millon, ninhydrine, or K ferrocyanide reactions, nor the molybdate reaction characteristic of the venom of *Bufo marinus*. The secretions of the first and third were wholly nontoxic; that of the second caused general contractions in pigeons, but the latter always recovered; those of the last two were very toxic. The venom of *Tr. nigromaculatus* was effective on mammals, birds, batrachians, and reptiles, but the lethal dose could not be determined. It acts on the nerve centers, and later causes hemorrhages. The parotid venom of *Ph. burmeisteri* acts very similarly; its lethal doses were found to be: intravenously in pigeons 0.15 mg., dog (6-8 kg.) 1.8 mg., rabbit (1.5 kg.) 0.5 mg.; intramuscularly, pigeon 3 mg., guinea pig (400 gm.) 4 mg.; orally in *Lachesis jararaca* 0.5 mg. The venom of *Tr. nigromaculatus* lost its toxicity when heated 30 mins. at 45°; that of  $p_H$  was only slightly affected after 15 mins. boiling.

J. J. WILLAMAN

Employment of Paris green at the anti-malarial station of Porto Torres, Sardinia (CLUZEL) 14.

## 12—FOODS

F. C. BLANCK AND H. A. LEPPER

The quartz lamp as a detector in the food industries. THEO KÜHLEIN. *Chem.-tech. Rundschau* 44, 602(1929).—The evacuated and non-evacuated types of Hg vapor lamps are briefly described. The use of these lamps for analytical purposes depends on the fluorescence of substances in ultra-violet light. Sausage may be tested since flesh is red and cartilage bluish. Meat exts. and yeast exts. may be distinguished by means of their yellow-brown and grayish fluorescences. In ultra-violet light whole milk is canary yellow, skim milk, colorless, butter, yellow and margarine, bluish. Adulteration of butter by 25 per cent margarine can be detected by this means. The yellow fluorescence of pure cacao butter is lost on adulteration with coconut or palm-kernel fat. In a similar way ultra-violet light can be applied to the examn. of flours, sugar, fruit juices and alc.

E. PICKERING

Eliminating insect pests from foods by fumigation. L. V. BURTON. *Food Ind.* 1, 366-70(1929).—The use of the vacuum fumigator for the disinfection of cereal products, candies, nuts, cheese, cured meats and dried fruits is described and the principal pests affecting each food are enumerated. Either HCN or CS<sub>2</sub> or combinations of CS<sub>2</sub> and CO<sub>2</sub> are used. The CO<sub>2</sub> decreases the explosion hazard. The CO<sub>2</sub>-CS<sub>2</sub> mixt. may also be used in protected open tanks because the mixt. is heavier than air. In vacuum fumigation of foods, CS<sub>2</sub>-CO<sub>2</sub> mixt. is preferred, the amt. of CS<sub>2</sub> required being from 30 to 14 lbs. per 1000 cu. ft.

C. R. FELLERS

The food value of Eleusine cereals. I. Chemical and biological analysis of Afri-can cereals. A. ORRU. *Boll. soc. ital. biol. sper.* 4, 281-7(1929).—The cereals tested were *Eleusine atra*, *E. fusca* and *E. alba* grown in Eritrea. By feeding 5 rats exclusively with eleusine, it was possible to keep them alive and in good condition for a period of at

least 65 days. The increase in wt. was considerable (av. 209%). *Eleusine* flour has a higher nutritive value than corn meal.

**Cereal chemistry in Europe.** D. W. KENT-JONES. *Food Ind.* 1, 392-3(1929).—A survey. PETER MASUCCI. C. R. FELLERS

**Peroxides in the cereal industry.** G. VAN DER LEE. *Food Ind.* 1, 352-3(1929).—Benzoyl peroxide, known commercially as "Novadelox," is widely used in the bleaching of flour. The action is largely on the carotin of the oil. The oil content of wheat flour is approx. 1% and the carotin content is 0.0001-0.0002%. Active O evolved from benzoyl peroxide combines with the unsatd. carotin, giving a stable colorless carotin (-) compd. Theoretically, 0.0005 to 0.001 g. of benzoyl peroxide can bleach the carotin present in 100 kg. of flour but in practice 2 to 3 times as much is used because a part of the peroxide combines with other flour constituents. Whole-wheat flours cannot be bleached white because of the brown bran fragments. About 24 hrs. is required for the reaction to go to completeness and thorough mixing is advocated. C. R. FELLERS

**A gluten washing machine.** T. R. JAMES. *Cereal Chem.* 6, 244-6(1929).—Illustration and description of a machine for washing glutes and thus eliminating the personal equation. L. H. BAILEY

**Wheat flour studies. XV.** The use of the viscometric method for measuring the proteoclastic activity of flours. ARNOLD H. JOHNSON, B. L. HERRINGTON AND SAMUEL G. SCORR. *Cereal Chem.* 6, 182-96(1929); cf. C. A. 22, 2009.—A viscometric method of detg. the proteoclastic activity of flours is described, according to which the digested flour-water suspension is extd. 3 times with 1 l. of water. The residue in a vol. of 100 cc. is acidulated and the viscosity detd. When a patent flour-water suspension is digested at 30°, for 24 hrs., about 10% of the protein is changed to the extent that it no longer imbibes water on acidulation. The effects of comparable treatment on the proteins are greater in low-grade flours. E. g., 47% of the proteins of a second clear flour no longer imbibed water when the flour-water suspension was digested at 30°, for 24 hrs. Rate of decrease in viscosity was greater at higher temps. Amino N as detd. by both the formol titration and the Van Slyke methods increased during autolysis of flour suspensions. The formol titration is probably the most convenient method of detg. the proteoclastic activity of flours, but information is not given concerning the abs. quantity of protein changed by the hydrolysis. L. H. BAILEY

**Modifications of Rumsey's method for the determination of diastatic activity in flour.** J. G. MALLOCH. *Cereal Chem.* 6, 175-81(1929).—Several modifications of Rumsey's method for the detn. of diastatic activity are proposed. These are (a) control of acidity, (b) correction for the vol. of the flour, and (c) improved procedure for the detn. of the blank. A method for obtaining diastase-free flour is outlined. L. H. B.

**Determination of degree of acidity of flours by colorimetric spot-test.** RAYMOND HERTWIG AND J. S. HICKS. *Cereal Chem.* 6, 162-3(1929).—Flour standards representing different Beta Chlora treatments, as 1.5 oz., 2.0 oz., 2.5 oz., etc., Beta Chlora, resp., per barrel, are used for comparisons with the flours being tested. The unknown flour and the standards are placed in adjoining depressions of a porcelain spot plate. The surfaces of the flours are smoothed with a spatula or "slick" and a drop of suitable indicator such as chlorophenol red, bromocresol green, or bromothymol blue soln. is placed on the center of each flour portion, allowed to remain for 3 to 5 mins. and then the color on the unknown is matched with the standards. Such a method is useful in mill control to ascertain the uniformity of treatment of the flour. L. H. BAILEY

**Hydrogen-ion determination in flour and bakery products.** E. O. WHITTIER AND EMILY GREWE. *Cereal Chem.* 6, 153-62(1929).—The H-ion concn. of a 20 g.-100 cc ext. of a flour, cake, or bread is not the same as that of the unextd. substance. The Bailey electrode method and the capillary quinhydrone method applied to such exts. give results that may, in general, be safely used for comparative purposes, but should not be considered the true values for the unextd. samples. The ball quinhydrone method, in which no water or only a negligible amt. is necessary, gives readily reproducible  $p_H$  values when applied to flours and bakery products in the range 5.0 to 8.0, and the time required is comparatively short. The values so obtained more nearly represent the true H-ion concn. of the samples than those obtained by the other methods discussed. L. H. BAILEY

**Carotinoid pigments in flour.** C. G. FERRARI AND C. H. BAILEY. *Cereal Chem.* 6, 218-40(1929).—Pure carotin concn. can be measured by detg. the transmittancy at wave length 435.8 mm. of its petr. ether soln. A reasonable basis for the assumption that dil. solns. of carotin and petr. exts. of flour are similar has been established. These facts permit the correlation of the transmittancy of flour exts. with carotin concn. in accordance with the procedure described for pure carotin. It has been shown that the

presence of a small quantity of another pigment like xanthophyll would not cause an error of any significance in the estn. of flour color expressed as carotin alone. For the purpose of flour-color measurement the assumption is made, therefore, that the flour pigment is carotin. In carrying out such measurements the transmittancy of a gasoline ext. of flour is detd. The concn. of pigment expressed in mg. of carotin per l. of soln. is learned by consulting the curve showing the relation between per cent transmittancy and carotin concn. The concn. of pigment in the flour is then computed from the proportion of flour and solvent used in prepg. the ext., and the results are expressed as parts of carotin per million parts of flour.

**Granulation of flour and its relation to baking quality.** C. B. KRESS. *Cereal Chem.* 6, 202-14(1929).—The granulation of a flour makes only a little difference in its baking quality; the big difference is due to the wheat from which it is made. A flour of medium granulation has a tendency to produce a more even grain. Considering vol., color, texture and grain equally, the best flour is found in the 30% to 40% of medium granulation. That is, if one sifts out the coarsest and the finest flour until there is about 40% left of medium granulation, the best baking quality is obtained. The granular flour produces a little more acid than the fine flour during the first, second and third hrs. of fermentation. At the end of 4 hrs. the dough made from the granular flour has the same acidity as that made from fine flour. It is evident, from the rate of evolution of gas, from the increase in acidity and from the vol. of the dough during fermentation, that both fine and medium granular flour, such as is ordinarily made in good milling, has practically the same rate of fermentation.

**A single-figure estimate of baking scores.** R. K. LARMOUR. *Cereal Chem.* 6, 164-74(1929).—As there is no standard system for reporting bread characteristics, it is necessary for the baker to score the loaves produced, and thereby set a value upon the various characteristics observed. Loaf vol. may be accurately detd. and recorded in definite figures but texture, color, appearance, oven spring, etc., are not so readily detd. Arbitrary values must be placed on these characteristics if they are to be included in scoring. L. suggests weighting the various factors, and having them related; thus 30 cc. loaf vol., 2 points in texture, 3 points in color, 6 points in appearance and 6 points in absorption are each equiv. to 6 points in the final bread score. All the points in the score are added together to form the final bread score.

L. H. BAILEY

**A quick viscometric method for measuring the staleness of bread.** L. P. KARACSONYI. *Cereal Chem.* 6, 241-3(1929); cf. *C. A.* 23, 3029.—Ten g. of the crumb of the bread is broken in small pieces and wetted with distd. water, worked through a No. 5 XXX silk bolting cloth into a porcelain dish, completely transferred to a 250 cc. Erlenmeyer flask, the bread and water to weigh 100 g. K. used a viscometer similar to that of Luers and Ostwald (1919). This instrument had a water equiv. of 74 secs./5. Detns. were made at 20°. Reproducible results were obtained.

L. H. BAILEY

**A technological method for the study of yeast.** E. E. WERNER AND WM. SIEDHOFF. *Cereal Chem.* 6, 196-201(1929).—Yeasts are tested by subjecting them to the same conditions in bread doughs. A standard flour is used. One series of doughs is made by adding little or no sugar and duplicate doughs are made by the addn. of 5% of sugar. Variations in the yeasts will be manifested in these doughs.
